Vines.—The earliest Vines should be pruned at once, as advised in a former calendar. It is not necessary to wait till all the leaves have fallen before pruning, only the wood must be brown and hard and the leaves turning yellow. The pruning will cause the Vines to go more quickly and thoroughly to rest. It is important that the house be thoroughly cleaned and the Vines also. Any weakly Vines or those in an unsatisfactory state may be improved by removing the soil down to the roots and replacing with fresh turfy loam with an admixture of a tenth of old mortar rubbish and a fifteenth part of half-inch bones, lifting any roots available for the purpose, laying them out upon the fresh compost, and covering them not deeper than 6 inches. This is best performed before the fall of the leaf. It is a mistake to allow Vines when at rest to become very dry at the roots; comparative dryness is desirable, yet great injury is caused by allowing the soil to become dust-dry, especially Vines in pots which are to be started in November; those for that purpose being now completely at rest, the wood thoroughly ripe, the laterals cut close home, and the canes shortened to about 6 feet, more or less according to the situation of the plump eyes. Whilst the cuts are dry dress them with styptic or "knotting" to prevent further trouble from bleeding. They should be kept in a cool airy house. The borders of the earliest houses—i.e., the outside borders, should have a covering of some kind to protect the roots from the heavy autumn rains, which reduce the temperature considerably. Glass lights are every way preferable, throwing off heavy rains and allowing the sun's heat to penetrate the soil. We, however, with many others, are obliged to be content with a covering of leaves and litter after the weather sets in cold; and though convinced that good Grapes can be produced without material to throw off the rains, yet reason and practice justify their employment wherever available for the exclusion of moisture in undue proportions to the requirements of the Vines.

Late Grapes, whatever may be said to the contrary, keep much better when the roots are not chilled by the autumn rains; therefore tarpauling, shutters, or thatched hurdles should be held in readiness for use when required, avoiding, however, their unnecessary use. Grapes ripening will require a dry warm atmosphere with a free circulation of air, keeping the laterals well stopped, which if allowed to grow cause damp and decay of the berries and excite root-action. Ripe Grapes should be looked over frequently for the removal of shanked or decayed berries.

Wasps are very troublesome this season; scrim canvas placed securely over the ventilators excludes them better than anything we have tried.

Young Vines, especially those that have made a strong growth, are late in ripening and should be assisted with fire heat, maintaining a minimum of 65° and maximum of 75° from fire heat, continuing it until the wood is ripe, accompanied with free top and front ventilation. Similar remarks apply to late Grapes not yet ripe. Ventilate freely and maintain by artificial means a temperature of 75° to 70°, falling a few degrees during the night, discouraging any further growth by the removal of the laterals as they are produced.

Peaches and Nectarines.—In the earliest forced houses it is undesirable to allow the borders to be too much saturated and cooled by the autumnal rains, therefore houses from which the lights have been removed should have them replaced as soon as the rains occur, admitting, however, full ventilation top and front. In the latest houses it may be desirable, if the autumn be cold and wet, to assist the ripening of the wood with a little fire heat, admitting air abundantly, and cutting out the bearing wood of the current season so as to admit light and air to play freely about next year's fruiting wood, remembering that a crowding of the foliage only tends to immaturity, so that if the shoots are too thick thin them well out, it being better done now than at the winter pruning, of which little ought to be required in the case of trees grown under glass. A good syringing will occasionally be required to free the foliage of red spider, but avoid anything approaching to a confined moist atmosphere, yet affording copious supplies of water to the inside borders, so as to prevent premature falling-off of the foliage.

Cucumbers.—With shorter days the cold of the nights increases, which necessitates the earlier closing of the house, and the employment of the syringe also earlier, so as to have the foliage fairly dry by dusk. Fire heat will also be necessary to maintain a temperature of 75° to 70° by artificial means, falling about 5° during the night. Afford every encouragement to the autumn fruiters, removing the first fruits, also the male blossoms and tendrils. No shading will now be necessary, and avoid morning syringing, damping being sufficient. Sow at the middle of the month for a supply of fruit at Christmas onwards. Telegraph (one of the best), Osmonston Manor, and Duke of Edinburgh (Munro's) are suitable varieties. Any sorts difficult to secure seed of may be increased by cuttings, placing them in a brisk bottom heat and covering with a hand or bell-glass until rooted, as they will be in about ten days.

Melons.—The last batch will be well up the trellis and showing blossoms. If the crop be wanted quickly these early blossoms should be impregnated. A portion of the plants may have the first fruits removed, and will afford a later and fuller crop from the second laterals. Earth-up the plants after the fruit is set, not before; and after this be sparing of the syringe, employing it only during bright afternoons, and then early, taking care not to overwater at the roots, yet maintaining a genial moisture in the atmosphere by sprinkling; promote also healthy root-action by proper moisture in the soil. Plants in frames will require no more damping overhead, and should only have sufficient moisture in the soil to keep the foliage from flagging, keeping it rather thin and the fruit elevated above it on inverted flower pots, applying good linings so as to finish off the ripening satisfactorily, which requires a warm, dry, well-ventilated atmosphere.

PLANT HOUSES.

Stove.—In removing stove plants from conservatories care must be taken when they are returned to the stove not to excite them into growth, which from the higher temperature they are likely to be; seeking rather to prevent growth by withholding water so as not to injure the foliage, and by keeping the atmosphere drier than during the summer. This more particularly applies to Allamandas, Bougainvilleas, Clerodendrons, Ixoras, &c., that have ceased flowering; but plants that were started late in the season will continue flowering for some time yet, and at no time are they more acceptable than in late summer and autumn. Many of the freest-flowering stove plants do best in an intermediate house in winter, whilst others, as Ixoras, require a higher temperature. The temperature should now be 65° to 60° at night, 70° to 75° by day from fire heat, with an advance from sun heat of 10°, ventilating freely. In dull weather damping twice a day will be sufficient, syringing early in the afternoon any plants in growth so as to have the foliage fairly dry before nightfall, but any plants going to rest need not be syringed. Shading except for very tender foliage plants will not longer be required. The blinds should be thoroughly dried and stowed away. The glass both inside and outside should be well cleaned, as the plants require after this all the light that can be given them.

Orchids.—The temperature should still range from 75° to 85° by day in the East India house, maintaining it until the end of the month, when a gradual reduction must be made, for the present keeping up a growing atmosphere, giving every possible encouragement to Aërides, Saccolabiums, and Phalaenopses. The blocks, baskets, and pots must be damped in the morning, and the plants will be benefited by being syringed on the afternoons of

bright days. Shade as little as possible, only sufficient to prevent the sun scorching the foliage. Dispense with shading altogether in the Cattleya house, thoroughly cleansing the glass inside and outside in order to afford all the light possible, it being very important to have the growths well ripened. All pseudo-bulbous plants having completed their growths should have an increased amount of air, but no change in the treatment of Orchids should be brought about suddenly. *Cattleya citrina*, *Laelias acuminata*, *albida*, and *majalis* should be thoroughly exposed to light, placing *Laelia purpurata* and *Cattleya Mossiae* in the warmest part of the house to enable them to complete the growth as soon as possible. *Calanthe vestita* and *C. Veitchii* may have weak liquid manure, as the stronger the pseudobulbs are the stronger will be the flower spikes. See that scale is kept from the leaves. *Calanthes Masuca* and *C. veratrifolia* may be repotted if not already done. *Odontoglossums* that started late into growth may be shifted into larger pots without disturbing the roots, or as little as possible. In order to have the growths of Orchids well matured before the dull days the plants should be exposed to as much sun now as they will endure without injury, for unless the growths be well matured the plants will not flower satisfactorily.

TRADE CATALOGUES RECEIVED.

B. S. Williams, Victoria and Paradise Nurseries, Upper Holloway, London, N.—*General Bulb Catalogue and Lists of New Plants, Fruit Trees, Roses, &c.*

New Plant and Bulb Company, Lion Walk, Colchester.—*Catalogue of Lilies, Orchids, and Miscellaneous Bulbs.*

Webb & Sons, Royal Seed Establishment, Wordsley, Stourbridge.—*Illustrated Catalogue of Dutch Flower Roots, &c.*

Daniels Brothers, Royal Norfolk Seed Establishment, Norwich.—*Illustrated Catalogue of Bulbs, Fruit Trees, Roses, &c.*

John Laing & Co., Stanstead Park Nursery, Forest Hill, London.—*Catalogue of Bulbs, Roses, Hardy Plants, &c.*

TO CORRESPONDENTS.

. All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

ADDRESS (R. G.).—Write to Kent & Co., High Holborn, London, who can probably supply you with what you require.

DESIGNS FOR FLOWER BEDS (W. A. and S.).—"The Parks and Gardens of London," ss. 5d., post free from this office, contains many designs and modes of planting flower beds effectively.

PROTECTING FRUIT (C. Allen).—As all your scares fail to frighten the birds and you cannot shoot them, your only remedy is to cover the trees with nets.

POTATOES (J. B.).—The produce you mention is large. Our correspondent wishes to be told of a furniture oil that will destroy and prevent worms in woodwork.

PRESERVING APPLES AND PEARS (Zephyr).—We store them thinly in a rather cool and dark place. Mr. Cannell, Swanley Nurseries, Kent, can supply you with the list you require.

VINES OVER-LUXURIANT (A Nine-years Subscriber).—The Vines being young no great injury can have been done by neglect in stopping the shoots. Set to work at once and cut away all the laterals to within three or four leaves of the rods or canes, and any subsequent growth they may make stop at the first leaf, and the rods cut back to the top of the rafter. This will admit light, and by continuing the fire heat and ventilation until the leaves turn yellow there is no reason why the wood should not ripen perfectly. See notes on young Vines in this week's "Work."

PROTECTING TREES FROM CATTLE (Cartoon).—The most suitable are wrought-iron tree guards 6 feet high and 2½ feet in diameter in the centre, with flat bars upright, so that cattle or horses cannot get their heads through the bars and eat the trees. Their price is about 2½s. each. Standard trees only are suitable, having straight clean stems and well-formed heads. Beech must take precedence of all trees upon a chalky soil, and should be planted most extensively, the Purple-leaved also succeeding, and the Fern-leaved though a much smaller tree is very ornamental. English Elm, Chichester or Huntingdon Elm, Horse Chestnut, scarlet-flowered Horse Chestnut, Lime, red-twigged; Scarlet Maple, Norway Maple, Sycamore (this with Beech for the most exposed positions), variegated Sycamore, Scarlet Virginian Maple, Turkey Oak, Scarlet Oak, and Mountain Ash are all ornamental trees.

MENTHA PULEGIUM GIBBAITARICA (Juno).—This valuable green carpet-bedding plant is hardy, yet it not infrequently suffers by excessive wet during winter and spring, especially if it is planted in large masses. A good mode of wintering it is to plant very small tufts of it now on a dry south border, placing two or three rooted sprays together and about 3 inches apart in rows 6 inches asunder, or at such other distance that a small hoe can be run through the ground between them as required. The tufts should not be more than half an inch across in November. If much larger many of the plants are almost certain to damp-off. In very wet soils and districts the plants should be conveniently disposed for receiving the shelter of spare sashes, frame lights, or handlights. The Ivy-leaved Geranium is *L'Elegante*. It may be placed out of doors in summer, but colours best on the shelf of a light greenhouse, the plant not being overpotted.

BEES ATTACKING PEACHES (Zero).—You have no remedy against your neighbour, for you cannot prove that the bees which attack your fruit are his, and if you could it would be difficult in a court of law to prove trespass against the bees.

PEARS CRACKING (Gardenia).—Your soil is probably sandy and poor

where the Pear tree is growing. If you take away some of the present soil and replace with a rich compost it will improve the tree. Or the roots may have got into an ungenial subsoil, in which case dig a trench round the tree and cut away all tap roots tending downwards. We are sorry we cannot assist you with plans of flower beds, these depend so much on position and surroundings; but if you will send us the plans we will advise you how to plant them.

EGG PLANTS IN GREENHOUSE (S. S. T.).—At this season of the year Egg Plants do very well in a greenhouse provided they are not placed where there are sharp currents of air, such as near the ventilators; but the plants must be grown to a fruit-bearing state in a closer, warmer, and moister atmosphere than that of a greenhouse. The shelf of a stove or a dung-heated frame is necessary for growing the plants well until they nearly arrive at maturity. They must be watered copiously yet carefully, and syringed frequently to keep down red spider, with which the plants are especially liable to become infested.

ROSE CULTURE IN A CLAY SOIL (Pierre Nolting).—We consider the failure of your Roses is attributable to faults of soil and not of climate. Drainage, mechanical division, and plenty of rich stable or farmyard manure are the prime movers in the successful treatment of such soil for Rose culture. Make drains of 2-inch pipes 4 feet deep and 20 feet apart, then spread a layer 6 or 8 inches deep over the surface of any hard gritty matter. There is nothing better for the purpose than coal ashes, and if you cannot get enough of them take road scrapings, stone chippings from a mason's yard, or, better still, if there should be any old buildings in course of demolition near you, get all the old bricks and mortar you can and pound them to pieces of the size of a walnut. Spread a layer of equal thickness of manure upon the grit, and then trench the soil 18 inches deep, taking pains to mix the grit and manure with the whole of the soil as it is turned over and chopped to pieces. After this is done lose no time in marking the stations with stakes, putting in a stake for every Rose, and working a little more manure and coal ashes into each station to insure a good start, and that no water shall accumulate about the roots. Seize a favourable opportunity in November for planting when the soil is not too wet; secure each Rose to its stake, but put no dung, litter, or mulching of any kind upon the surface over the roots, as is done so advantageously in light sandy soils, for the greater the exposure of such heavy soil to frost, sun, and wind the better for the soil and the plants growing therein.

PRUNING DOUBLE FUZZE (An Irish Subscriber).—As a mass of beautiful golden flowers is usually required, the plants should have such pruning as they require as soon as possible after the flowers fade. At this season of the year only irregular growths should be shortened. The price given for clipping hedges varies in different districts. In Lincolnshire and Yorkshire the men usually earn 3s. per day at such work.

MARÉCHAL NIEL FOR GREENHOUSE (W. P. M.).—We should make a rich deep station for the Rose outside the house, and train the growth inside after the manner of a Vine. We have a Rose thus planted that gives us hundreds of grand blooms yearly. Perhaps your plant outside is too closely pruned. This Rose always flowers most freely from shoots made late in the summer.

LAVERNE FROM CUTTINGS (E. B.).—Slips 3 or 4 inches in length, or cuttings of the same length inserted now in sandy soil under handlights, will strike readily. Slips will also strike if inserted firmly in the sandy soil of a shady border. The white-foliaged plant is *Cineraria maritima*. Cuttings inserted now in sandy soil in pots placed in a frame and kept partially shaded will strike. The other plant is a *Sedum*, but we cannot determine the species as the spray was much crushed. It may be increased readily by cuttings treated the same as *Geranium* cuttings, or by division of the roots in the spring.

GRAPES DECAYING (J. I. C.).—Cut out decaying and moulded berries promptly, promote a drier atmosphere, and ventilate efficiently; also apply a little fire heat during cold nights to prevent the berries becoming cold and thereby condensing the moisture on their surfaces. The same treatment will arrest the scalding of which you complain. The minimum temperature of the house should not be lower than 55°, with a little ventilation at the top of the house at night.

PREPARING GROUND FOR POTATOES (Robertson).—The part you do not propose planting with Potatoes next year may be occupied with any description of vegetable crop excepting "roots," but for alternating with Potatoes a cereal crop would be preferable, such as Wheat, Barley, or Oats. The part required for growing Potatoes next year should be manured in autumn and then ploughed or dug-in. In March, or so soon as the soil is in good working order, cross-plough or drag and dress with lime at the rate of eighty bushels per acre, and harrow lightly. No manure to be given at the time of planting; and as the ground has long been under Potatoes, it is probable that a dressing of lime only without the manure would improve the quality of the tubers.

PRUNING SHRUBS (Idem).—This is the worst time of the year for cutting back overgrown evergreens or other description of shrubs. Any irregularities of growth may be cut in now, but not so as to denude the plants of too much foliage. Defer the cutting-back until the close of March or beginning of April, and even then if the shrubs are old and much overgrown it is doubtful if they will break satisfactorily from the old wood.

BRITISH PLANTS (Scintion).—The following list will perhaps meet your requirements:—*Achillea Millefolium* rosea, *A. tomentosa*, *A. Ptarmica* flore-pleno; *Aconitum Napellus*, *Acorus Calamus*, *Agrimonia Eupatoria*, *Ajuga reptans*, *Alchemilla alpina*, *Anchusa ochroleuca*, *Anemone nemorosa* flore-pleno, *A. Pulsatilla*, *Antirrhinum majus*, *Aquilegia vulgaris*, *Arenaria lariofilia*, *A. verna*, *Arneria maritima*, *Asarum europæum*, *Asperula odorata*, *Betonica officinalis*, *Caltha palustris* flore-pleno, *Campanula glomerata* var. *alba*, *C. latifolia* var. *alba*, *C. patula*, *C. Rapunculcus*, *C. rotundifolia* var. *alba*, *C. Trachelium* var. *alba*, *C. Cardamine pratensis*, and double and purple and white vars., *Cheiranthus fruticulosus*, *Colchicum autumnale* var. *flore-pleno*, *Convallaria majalis*, *Corydalis lutea*, *Cypripedium calceolus*, *Dactylis glomerata* elegantissima, *Dianthus cæsius*, *D. deltoideus*, *Epilobium angustifolium*, *E. hirsutum*, *Epimedium alpinum*, *Erigeron alpinus*, *Fragaria vesca* fol. var., *Fritillaria meleagris*, *Galanthus nivalis*, *Gentiana acaulis*, *G. verna*, *Geranium lancastriense*, *G. pratense* and vars. double blue and white, *G. sanguineum*, *Hepatica triloba*, *Hypericum calycinum*, *Lathyrus latifolius*, *L. pratensis*, *Lotus corniculatus*, *Lycynis diurna* plena, *L. Flos-cuculi* plena, *L. Viscaria* plena, *Lysimachia nummularia*, *Lythrum Salicaria*, *Myosotis palustris*, *M. sylvatica*, *Orobanch niger*, *Primula acaulis* and many vars., *P. elatior*, *P. farinosa*, *P. scotica*, *P. veris*, *Prunella vulgaris* laciniata,

Pulmonaria officinalis and var. *alba*, *Pyrethrum parthenium* vars. *flore-pleno* and *aureum*, *Pyrola media*, *P. rotundifolia*, *Ranunculus acris* *plenus*, *Salvia pratensis*, *Saxifraga aizoides*, *S. caespitosa*, *S. cernua*, *S. decipiens*, *S. denudata*, *S. elongata*, *S. elegans*, *S. Geum*, *S. granulata* and double variety, *S. Hirculus*, *S. hirta*, *S. hirsuta*, *S. hypnoides*, *S. incurvifolia*, *S. letevirens*, *S. leptophylla*, *S. muscoides*, *S. nivalis*, *S. oppositifolia*, *S. platypetala*, *S. stellaris*, *S. umbrosa*, *Scrophularia nodosa* *variegata*, *Sedum acre*, *S. albescent*, *S. album*, *S. anglicum*, *S. dasyphyllum*, *S. Forsterianum*, *S. glaucum*, *S. micranthum*, *S. oblongum*, *S. reflexum*, *S. rhodiola*, *S. rupestre*, *S. sexangulare*, *S. Telephium*, *S. villosum*, *Sempervivum tectorum*, *Silene acaulis* and var. *alba*, *S. maritima* and var. *flore-pleno*, *Solidago virgaurea*, *Spiraea Filipendula* and var. *plena*, *S. Ulmaria*, *Statice bniervosa*, *S. nana*, *S. rariflora*, *S. reticulata*, *Stellaria Holostea*, *Stipa pennata*, *Symphytum officinale* fol. var., *S. tuberosum*, *Tanacetum vulgare* *crispum*, *Teucrium Chamædrys*, *Thalictrum alpinum*, *T. minus*, *Thymus citriodorus* *aureo-marginatus*, *T. Serpyllum variegatis*, *Trifolium repens* *pentaphyllum*, *Trollius europæus*, *Tussilago Farfara* *foliis variegatis*, *Verbascum nigrum*, *Veronica Chamædrys*, *V. hybrida*, *V. spicata*, *Vinca major*, and *V. minor*. Many are in cultivation. For height, time of flowering, and colour consult a catalogue.

INSECT (*J. Weaver*).—We cannot name any insect unless we see a specimen.

NAME OF FRUIT (*J. M.*).—Duncan.

NAMES OF PLANTS (*L. W.*).—1, *Adiantum pubescens*; 2, *Panicum variegatum*; 3, *Pteris serrulata*; 4, *Fittonia argyoneura*. (*Rev. E. C.*).—*Fuchsia coccinea*. (*J. S. E.*).—*Acer Negundo variegata*.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

THE CULTIVATION OF WINTER TARES OR VETCHES.

UPON certain soils winter vetches are an important fodder crop, and they may be styled a preparatory crop in the rotation adopted upon different soils. The cultivation may be considered comparatively trivial and inexpensive. Under ordinary farming few farmers ever think of doing anything for them except merely ploughing, sowing, harrowing, rolling, &c.; but upon the home farm where winter vetches are to be grown, and if not in high condition, manure should be applied. The land should be quite clean before ploughing and sowing, for if only a few bunches of couch grass or docks appear they should be forked out by hand, and thus save the extra horse labour. In the event of a considerable quantity of couch being in the soil a short fallow will be necessary, the best plan being to rafter or half-plough the land and then scarify across the rafters, which will lift out the couch and enable it to be dealt with by the usual process of dragging, harrowing, and rolling. The best implement of the drag kind we have seen is that recently invented and manufactured by Howards of Bedford, and named the improved self-lifting drag-harrow, with bud tines covering $4\frac{1}{2}$ feet of ground. This is an admirable implement, and upon all land after ploughing and undergoing the fallow process it is calculated to supersede all other drags or scarifiers on account of its easy draught and effective working. No home farm should be without it, as it is useful for many purposes in ordinary cultivation.

Vetches may be drilled if only for the purpose of burying the seed better, and it is usual to sow two bushels of vetches and one bushel of rye per acre upon that portion which is intended for the earliest use, whether for sheep-feeding or for cutting-up to feed horses, cattle, &c. The portion required for second early purposes may be seeded with the same quantity of vetches with one bushel of winter oats per acre. The portion required for the latest use should have, in addition to the same quantity of vetches, one bushel per acre of White Tartarian oats, for this kind of oat will bear the weather of an average winter; and as they are the latest sort with which we are acquainted they will remain in good condition for cattle as long as the vetches are available. The object of sowing corn with the vetches is for the purpose not only of protecting them during the winter months, but also to hold them up from off the ground, in which case there is not so much waste when fed off by sheep, and the vetches retain their soiling value longer for cattle and horses. We are aware that upon some light land hill farms sowing corn with the vetches is objected to; but there is no objection we have ever heard of when sown upon loamy or mixed soils. It is said, and perhaps with some truth, that upon certain poor and light soils the

growth of cereals in connection with a pulse crop interferes with the well-doing of the corn crops which follow. There is, however, a far more serious objection to vetches when grown upon either chalk hill land or light gravels, and we have often heard it designated as poison to the succeeding crops, although the vetches may have been fed-off by sheep eating oilcake at the same time. We have always thought that the mischief arises from the peculiar way in which vetches root in the land, and have often observed the numerous and minute white rootlets that completely intersect the soil whereon vetches have grown. From this circumstance it is that upon light gravelly, chalky, or sandy land, the soil which was already too light and porous is made still more so by the decaying fibrous roots of the vetches, and this is in some of our driest seasons fatal to the root crops which follow.

There is, however, another side to the picture, because our experience has shown us that upon heavy land this peculiar rooting of the vetches has a beneficial effect upon clay or strong soils. The rootlets of the vetches search the soil in every direction and make it pervious to air and water after the decay of the roots, and this is one of the reasons why vetches are recommended as a double crop with beans, the former intersecting the soil with surface roots, whereas the latter dive down into the subsoil with a single taproot. In this way a capital preparatory or fallow crop is produced, not only valuable in its own produce, but providing for the succeeding wheat or barley crop in the most economical and efficient manner. The sowing of vetches upon strong soils raises an important question, it being the only way in which sheep can be profitably and advantageously fed on the fallow break. Upon light and dry soils we can grow capital roots to be fed-off by sheep in the autumn and winter months; but upon strong flat-lying land this cannot be done, for upon such land at such a time of year the tread of the sheep would be positively injurious, whereas upon the light soils it is the best known provision for cereal produce.

We will now refer to the advantages of vetches fed-off in the summer months, so that as fast as the land is cleared it may be resown with mustard, the value of which is, that it may be either fed with sheep, or, if the season is too wet for folding, the crop may be ploughed under as a preparatory crop for wheat. We have often seen a crop of mustard as high or higher than the hurdles, so completely buried in the act of ploughing, that to a common observer it would not be known a green crop had been grown thereon. This is done best by the use of the skim coulter with a short chain and iron weight attached to the plough, which drags the green crop down and buries it so entirely as to resemble a fallow. Thus with vetches fed-off and mustard succeeding either fed by sheep or buried, we have one of the finest preparations known for wheat upon strong land; and when the sheep have eaten cake whilst feeding no further manuring is required, and the land may then be ridged-up and sown at the first and earliest opportunity, which is so essential to the production of a full crop of wheat upon strong and difficult tillage land.

Vetches are sometimes sown as a crop to be harvested. We, however, cannot recommend it with confidence to the home farmer, for notwithstanding the crop itself often proves valuable, and although the land would be kind and mellow after the crop has been harvested, yet it is an exhausting crop as regards the manure question, and the haulm of vetches is rarely obtained in such condition as to make it of consequence as cattle fodder. In this latter respect it will not bear comparison with a crop of peas, especially if an early sort is selected, for it is somewhat against seeding vetches that the harvest is usually later. It must be admitted, however, that winter vetches are often dear, sometimes from 10s. to 12s. per bushel, at which price they pay well for growing. The pulse or grain of vetches is of good feeding value for cattle, horses, and pigs, and in their composition and feeding properties they very much resemble lentils, which contain a large amount of flesh-forming materials. In the event of a wet harvest, if the vetches were injured for seeding purposes they would still

have a large feeding value, for we have known them when cheap purchased for feeding sheep and cattle, and mixed with linseed cake. Both vetches and cake, however, should be reduced to meal, and in feeding it is then best and most conveniently mixed with cut roots without any waste.

Sometimes where winter vetches are grown for the purpose of cutting-up for cows as a soiling crop only, and a succession of food required, Italian rye grass is often sown in the vetches, and when the vetches and rye are drilled at 9 inches it offers a good opportunity for sowing the Italian grass in the early spring, and horse-hoeing the land between the rows with narrow hoes to bury the seed. This is a plan more approved than sowing Italian grass with summer tares, because they are more apt to suffer from a blight called red rust than winter vetches. It is, in fact, very rare to see a crop of winter vetches suffer from blight, especially when rye or oats are sown with them as above directed, for it protects them and shelters them from the effect of blighting winds. We find many hill farmers dissatisfied with the growth of vetches, and only grow them for the want of a substitute, as they are so much approved as food for young lambs, having a change of saintfoin once a day. But we can with great confidence recommend a rotation for summer feeding without the vetches—viz., first rye, then trifolium three sorts, and some also spring-sown to be followed by turnips, and upon all these green crops mangolds may be used and preserved during winter and spring on purpose to assist the lambs whilst feeding on these crops, and saintfoin to the exclusion of winter vetches entirely, without deteriorating the preparation of turnips.

WORK ON THE HOME FARM.

Horse Labour.—In order that this may be set out in due course it is necessary that the rotation of cropping upon the home farm should be decided on, the sooner the better, as nearly as circumstances will permit. The most general rotation is the four-course—viz., first, roots; second, Lent corn or spring wheat; third, clover or grasses; fourth, wheat. This is in many parts of the kingdom a sort of customary rotation upon light kind soils, and it is very simple and comparatively easy to carry out if the manager understands the ordinary practical working and stocking of the land. But we cannot recommend this course of cropping upon a farm of really good land, which will bear a much severer course and yield more profit; but to those who are rather inexperienced the four-course rotation offers a good opportunity for the easy conducting of a farm. When once it is decided what rotation shall be pursued the work should now be laid out for the horses, and immediately after the harvest is complete. We will, therefore, consider the four-course system to have been decided on. In this case the first work will be, if any portion of the land coming in for roots is foul with couch grass, to at once commence a course of autumn cultivation, and, if steam power is available upon the farm or can be obtained by hire, to immediately begin the working of the land. Whether horse power or steam power is used avoid by all means, when there is much couch grass, ploughing the land; but instead of ploughing to scarify and break up the ground both lengthways and crossways a few inches in depth. In the event of sufficient horse labour being attached to the farm the dragging, harrowing, rolling, &c., should proceed immediately after the scarifier, and as soon as the grass, &c., is brought to the surface. It is a common practice to burn the grass and weeds as soon as it is quite free of the earth. This is a question of dry weather. We therefore prefer to diminish the labour of preparing the couch for burning by carting it away at once, although a portion of earth may be attached, and this may be done independent of the dry weather requisite for burning. If drawn to a heap when it becomes rotten it makes good manure for meadow land, and also a valuable article upon the farm for various purposes, such as placing at the bottom of pigsties, cattle pens, &c. Without being heaped at all, it may be drawn direct from the field and laid out upon any meadow or pasture land which has been closely fed, and if spread directly and after a short time chain-harrowed it will sink into the land and improve the herbage immensely. We have often tried it in comparison with farmyard dung, and found it quite equal in produce of grass, and superior in improving the quality of the herbage.

After the grass has been carted away the land may remain to be deeply ploughed after the wheat season is over, and fallowed for roots in the spring. Any portion of the roots lain which is quite clean should at once be seeded with trifolium on the corn stubble and dragged in, chain-harrowed, and left rolled. The seed required will be not less than 20 lbs. per acre, and three sorts for a succession may be sown. Rye for early sheep food or cutting up for cattle should now be sown, but the land should be ploughed, and a dressing of $1\frac{1}{2}$ cwt. of Peruvian guano may be applied with the best results. It will bring the rye very forward, and the manure not used up by the rye will be available for the succeeding root crop. The next crop generally sown for a fodder crop is winter vetches, but these need not have any manure applied as they may receive nitrate of soda in the spring if it is requisite to force them on early.

Hand Labour will still be various, for it will be quite necessary

in many cases to give the mangold crop another hand-hoeing, and in case of showery weather continuing we like to pick up the weeds and heap them in the field by women or boys, to be carted away when the roots are cleared in the same way the Swedes and common turnips will require to be treated. In many cases during the harvest and the delay caused by heavy storms it has been quite impossible to do the work necessary for root culture at the proper time.

Hedge-trimming, too, must be done, for this work is often delayed until the corn crops are cleared, and where the hedges consist of whitethorns the sooner it is done the better. We always prefer the early part of July for this work; if delayed until autumn the wood becomes hard and difficult to trim so closely as is really requisite. When fences are composed chiefly of high wide banks growing wood of various kinds it is not so important, but these should be done before Michaelmas; and where they are not required as fencing against horned cattle the wood may all be cut close to the bank, so that in the spring of the year the grass and weeds, together with the young shoots of wood, may all be cut together, and furnish good food for cattle and pigs.

FAMOUS POULTRY YARDS.—No. 2.

COMBE ST. NICHOLAS VICARAGE (REV. HANS F. HAMILTON).

(Continued from page 197.)

WE will now endeavour to describe Mr. Hamilton's chicken house. It is a magnificent structure, resting against a stone wall that forms its back; the front is entirely of glass lights like a greenhouse; the upper part of the back too is of glass, for it rises higher than the wall. Ventilation is secured by sliding windows in both front and back. The roof is tiled, but lined underneath with felt to keep it warm. The whole building is 75 feet long and 12 broad, and is divided into five compartments. It is so constructed that should Mr. Hamilton tire of the poultry fancy it may be easily adapted to horticultural purposes. The floor is dry—a perfect run for early chickens. Yet let us not be mistaken: though we have never ourselves had such a model house for early broods we once watched the growth of chickens in a similar one of a friend, and observed that they require to be moved when six or eight weeks old to less luxurious abodes or they outgrow their strength. At present it is put to an excellent purpose. Various fine Brahma and Dorking hens were sitting on the ground, among them one Brahma with wonderful pencilling; hens left thus to amuse themselves moult early and well. Each of the five compartments opens into a separate spacious orchard run sloping southwards, hurdling and wire netting divide them. In one of these were by far the best Dark Brahma pullets we have seen of late; lovely Silver-Grey birds in perfect condition, not of the weedy form we generally see with fine pencilling, but large, deep-bodied and heavily feathered.

Hence we somewhat retraced our steps, and passed down a pretty path leading through a shrubbery from the vicarage to the church. On the left was a gate, and through this seven charming runs quaintly irregular in shape, most of them well sheltered with shrubs and low-growing wood. The sheds are thatched and some of them very rustic; several are so arranged as to give access to more than one run: this struck us as being a great merit of Mr. Hamilton's arrangements, that from so many of the houses the birds can be turned out into one run while another is freshening. We peeped into one shed untenanted by birds, where was a pretty sight, an intelligent-looking Colley surrounded by her family. In another run was a late Dark Brahma cock of last year, a splendid fellow for which we augur many prize cards in the season. We have always had great faith in the worth of some late chickens allowed to run at ease for a year or more. The last two runs have no sheds at all, but veritable houses. Mr. Hamilton has ingeniously adapted two old-fashioned thatched cottages for poultry below and Canaries above. In one of the runs connected with them were four grand Dark Dorking hens, in the other a Dark Brahma cock of the Ansdell strain and a mixed troop of chickens, chiefly Dark Brahmas. The first part of the house we entered had apparently once been a barn; on one side are a row of exhibition pens, and underneath them a row of larger pens for moulting birds; along the beams are nailed many cards the signs of cups and prizes. The lower room of one cottage is devoted to sitting hens, that of the next is a roosting house. We scaled the queer old stairs, and there in perfect luxury were some wonderful Belgian Canaries. All live stock in the establishment is highly bred, and here we saw some of the best birds that Mr. Hamilton could procure in Antwerp. They seemed thoroughly to appreciate the quiet of their cottages, and we must say we at once longed to bring cottages into use for our feathered collection. But we must pass on. Back through these sheltered runs, we cross the church path and emerge at the bottom of the large orchard runs before described; with them on our right hand we pass along a smooth grass lawn at the bottom of the orchard, untenanted by birds at present and devoted to archery. Here behold the quaintest of all poultry houses, a disused omnibus! after many a jolt at last quietly grounded and well felted above, and a comfortable quarter it looked.

POULTRY.—DORINGS—Coloured.—Cockercels.—Cup, J. Taylor. 2, H. Lingwood, 3, F. Parlett. **Pullets.**—1, B. Smith. 2 and 3, T. C. Burnell. *Any other variety.*—Cockercels.—1, T. C. POINT CUPS. For the winner of the most points in Poultry, Pigeons, and Cage Birds—Mrs. J. T. Holmes, Bath. For the winner of the most points of Rabbits—J. Robertshaw, Thornton, Yorks.

JUDGES.—Poultry: Rev. G. F. Hodson. Pigeons: Mr. Tegetmeier. Canaries: Mr. W. A. Blakston. Rabbits: Mr. W. A. Allison.

HALIFAX AND CALDER-VALE POULTRY SHOW.

THIS Show was held at Halifax on the 31st ult., and was the fortieth Show held at that place. The entries in poultry and Pigeons were much larger than in any previous year.

Game headed the list with Black Red cockerels, the first and second were very good, the rest very poor; but, on the contrary, the pullet class was good, the first being a very correct bird in all respects. Brown Red cockerels were bad, but the pullets very good. Ducking cockerels were a fair lot, but pullets were also better in this case, the first a good one in all respects. Pile cockerels were young but promising; the best of this variety was the first-prize pullet. *Spanish* had only three entries, but the winners were about perfect. *Dorkings* five entries, and very good. *Cochins* very good, and in fine order; the cup for the best pen in the Show, Game or Game Bantams excepted, was awarded to a pen of Buffs, to which we preferred the Partridge or Spanish. In *Brahmas* first were Dark and second Light. *Hamburghs* were good, and mostly in fine feather. Game Bantams competed with the large Game for a cup and were a much better section, almost

every bird being good, the cup going to a most perfect Black Red cockerel in full feather.

Pigeons numbered 290 as against 80 entries last year, nor did the quality fail in the least when considered in proportion, the exhibits proving so good that very few were left unnoticed. Pouter cocks headed the list with some good birds, the cup in the first section being awarded to a Blue Pouter cock. Carrier cocks were a grand lot, first and second Blacks and third Duns, and the whole class highly commended. In hens first and third were Blacks and second Dun, and these were quite equal to the cocks. In Barbs first was a Black cock, and one of the best young birds we have seen in real back properties; the second, also Black, was close upon the first. Tumblers (Almond) were also good, the first hen and second cock a very close run; the third also a good hen. Short-faces of any other variety were—first a nice Yellow Bald, second Red Mottle, and third an Agate. In Dragons, of which there were three classes, there were some very good birds, while others were quite as wide of the true standard of a Dragon. Jacobins were very good; first and third Red, and second Yellow, the cup for this section being awarded here. Turbits were divided into two classes, and were very good, although many failed in the style of spike, which in many cases was set on far too low. English Owls were provided with four classes, but many of the best birds were quite ragged in moult, and not fit to be shown, the cup for the third section going to a Blue hen of rare quality of head properties. Antwerps were very numerous and good, but some of the pens were empty, and not a few in moult, the cup being awarded to the best Short-faced Silver Dun we have yet seen. Magpies and Swallows.—First a Black Swallow, as also the cup for the section; the second and third Magpies. Long-faced Tumblers were mostly Mottles, and Trumpeters poor. The Selling class was very good, some of the birds being quite equal in merit.

POULTRY.—GAME-Black Red-Cockerel.—1 and 2, W. Rudd. *Pullet*.—1, H. C. Mason. 2, H. Hicks. *chc, J. A. & H. H. Staveley. Brown Red-Cockerel*.—1, J. Hodgson. 2, R. Barker. *Pullet*.—1, T. JUDGES.—Mr. J. Dixon, North Park, Bradford; Mr. E. Hutton, Columbarian House, Pudsey.

SHOW OF THE OXFORD ORNITHOLOGICAL SOCIETY.

THIS Society held its annual Show of young Pigeons, bred by the members, on Tuesday the 3rd, in the Corn Exchange, Oxford. We have before given our opinion that such societies and such shows do much good. The prizes are almost nominal in value, and the members hold a friendly contest for comparison of their birds, shown *bona fide* as Nature made them. There were in all thirty-seven classes, though unfortunately some of them had no

entries. We regretted to see few visitors to the Show, doubtless owing to the fact that the great sale of Pigeons was going on in London, and drew away many prominent members of the Society.

Carriers were represented by ten Blacks, five Duns and two Blues in three classes. The first Black, deep in the moult, promises to be magnificent in wattle and beak; the second is nearly as good. The Duns and Blues, though so few, were good. **Pouters** had two classes; only one had entries. First and third were Blues, second Yellow. If we mistake not the first Blue will turn out a very remarkable bird. **Dragoons**.—This fashionable variety had five classes. The Blues were the best filled and the best class. The first Yellow was remarkable both for colour and form. The Whites were large. **Tumblers** had four classes, three only of which had entries. The first and second Short-faced looked to us very equal, and birds sure hereafter to make their mark. The class for Balds or Beards was almost entirely composed of the former variety. Two Beards, a Yellow and a Silver, alone appeared. **Turbits**.—We thought the winning Blues a little coarse, but good in face. We admired Mr. Salter's little bird (highly commended). The Silvers all came from one loft; we thought their peaks a little too low. In the Any other class a small Black, bright in colour, was first, a good Red and Yellow being respectively second and third. There were younger birds in this class still squeaking, which we think will one day be quite equal to the earlier winners. **Jacobsins**.—The first Red was a splendid bird all round, with wondrous colour, mane, and rose; his hood might, perhaps, be up a little more. In Yellows the first was best in hood and chain, but a little dull in colour; the second beautifully bright in colour, not quite so short in beak. All the prizes for Blacks went to one exhibitor; the first winner is small and very lustrous in colour. **Owls**.—One class of three had alone representatives, but their quality quite made up for the deficiency in the other two. First a Blue, second a Silver, third a Blue; all remarkable birds, but the first about the best for its age we ever saw. **Archangels** are indeed looking up. All the prizes went to Red Archangels, to the exclusion of a Black. First dark purple, forward, and through the moult; second and third will be as lustrous when older. **Magpies** were, of course, good in Oxford; the third (Black) looked younger than first and second, but will be wonderful in colour. The first (Yellow) was an extraordinary bird for colour; second and third nice Reds. **Fantails** had but two entries, pretty little birds of Scotch type and good carriage. **Antwerps**.—The Short-faced were all Silver Duns save one Blue-cheker, which took third prize. The Long-faced classes had large entries. *Any other variety*.—First and third were Blue Priests; the first the very best we ever saw; second a fine Pigeon.

The Show was judged by Mr. Allsopp, and his awards seemed to give complete satisfaction. On looking round one could not help being struck with the large number of prizes which were most deservedly awarded to Mr. S. Salter of Oxford. The lofts which can produce so many remarkable young birds of so many classes must indeed be something to see.

PIGEONS.—CARRIERS.—Black.—1 and 2, W. G. HAMMOCK. 3, J. CHANDLER. Dun.—1, W. G. HAMMOCK. 2 and 3, W. G. FLANAGAN. Blue.—1 and 2, W. G. HAMMOCK. **POUTERS**.—Pied.—1, J. CHANDLER. 2, T. HERRIFF. 3, R. SALTER.

INDIAN MINAH (MINO) BIRD.

WE have been asked for instructions by an Ashby-de-la-Zouch correspondent as to the treatment of the above bird, but we are not acquainted with one so designated. The name "Minah" may be mistaken for that of Mino, one of the order of Passerines, thus described by L. Figuier:—"The Passerine Dendroica [the Mino being one of that family] are characterised by a bill more or less strong, compressed on each side of the point. They feed on berries and insects, and comprehend numerous genera. . . . The Mino has been assigned to various families. Swainson places it among the Sturniidae; Gray in the sub-family of Graculinæ, under the family of Corvidæ. However, we prefer placing it as we have. They are sought after by the orientals in consequence of their gentle habits and the facility with which they imitate, like the Parakeets, all sorts of phrases and even airs. Their song is very agreeable. The Minos have a bill analogous to that of the Orioles, but their general form and habits approximate more to the Starlings, among which they ought to be ranged. They are

eminently social in their habits, searching for their food in large flocks, and passing the night in numbers on the same or on neighbouring trees. Their natural disposition being peaceful, lively, and confiding, they appear to prefer the vicinity of man's residence and the cultivated fields that surround his dwelling. They frequently attend upon flocks of sheep, to feed upon the insects that infest these ruminants' skins. In countries where locusts abound they are of great service to man by feeding upon them. The Isle of Bourbon was at one time so infested with locusts that it threatened to become uninhabitable. The idea was entertained of introducing some Minos, and these birds multiplied so fast that in a few years the pests had disappeared. Unfortunately the services of the Minos had to be paid for dearly, for they showed a *penchant* for fruit, and made great havoc among the cherries, mulberry trees, &c. When insects became scarce they even attacked the cereals and other crops. These Passerines readily habituate themselves to confinement, and in a short time become as tame as Starlings. Like these birds, too, they possess the talent of remembering and repeating words and various cries. They inhabit Africa, Asia, and Java. In their migrations they sometimes visit the southern countries of Europe, but they are rarely seen in France."

The illustration which accompanies the above remarks represents the bird to be in size betwixt the Golden Oriol and Starling with the centre portions of the outer flight feathers marked, as also are those about the sides of the head, from the back part of which some fan-shaped feathers gracefully project. The tail, like a Robin's, inclines upwards.—GEO. J. BARNESBY.

VARIETIES.

At the next Dairy Show to be held at the Agricultural Hall on the 10th, 11th, 12th, and 14th of October prizes amounting in value to close upon £600 will be offered for competition for poultry and pigeons. Last year it will be remembered there was a show of poultry, but the classes were somewhat limited, and were for birds of any age. On this occasion all the poultry classes will be for birds bred this year. The rules relating to trimming and other such practices will be very strict—a hint that exhibitors may do well to remember. The schedules will be ready by the end of the week. Mr. W. J. Nichols is the Hon. Secretary of the poultry department.

— WE are requested to announce that a Committee Meeting of the Poultry Club will be held in London on Wednesday, September 25th, when the members of the Committee are specially requested to attend.

— WE are glad to hear that more stringent rules than heretofore against trimming are to be inserted in the schedules of the Agricultural Hall and Crystal Palace.

— WE hope there is still some chance of the Oxford poultry and pigeon Show being held. We lately saw requisitions largely signed by the citizens in some of the Oxford shops requesting the Town Council to reconsider their decision, and we also understand that nearly half that body are about to memorialise the Mayor to convene a special meeting to reconsider the question.

— THE great sale of the studs of pigeons belonging to Mr. P. H. Jones and Mr. Roper attracted a large number of fanciers to Stevens's last week. The prices realised by the Turbits of the latter gentleman were even greater than those of the high-class fancy varieties of the former, though many of those sold for large sums—e.g., £12, £13, £14. One celebrated Black Turbit cock fetched £26, and others correspondingly high figures.

STRONG HIVES.

STRONG men, strong horses, and strong stocks of bees recommend themselves. The work they do when fairly tried commands respect and attention, gives confidence and satisfaction. Strong hives put their owners on the highest platform and above the influence of whims and prejudices, and they remain unaffected amidst popular agitations. On the contrary, apiarians with weak hives are easily influenced and soon catch the fever of whims and fancies and help to make them epidemic. New and better kinds of bees and hives are sought and purchased, fashions of every sort are followed, and money spent without returns or corresponding results. "The resting places" are always before us—at the next station. Shall we arrive at it soon? Some twenty years ago some of the Ayrshire bee-keepers on adopting the Stewarton hive predicted that straw hives would go out of fashion and be extinct in twenty years. Some of these prophets speedily returned from wooden to straw hives, and had them made on the Stewarton principle—that is to say, the bottom hives made of straw, with rims of wood on their tops for bars and slides. Since that time many enthusiasts have predicted the downfall of straw hives, they have been doomed again and again, and they have been refused admission to a Crystal Palace bee show; but somehow or other the national doomsday of such hives never comes. Present appearances indicate that this day will never come. Straw hives

were never in such vogue and demand as they are now. My time is taxed heavily to answer letters from all parts of England asking where large straw hives can be bought; and Mr. Samuel Yates of Manchester, who employs all the hive-makers he can find, is seldom able to meet the demand for them.

"To the enlightened apiarian," says the "RENFREWSHIRE BEE-KEEPER," "the day of monster supers, as of big straw skeps, is over. Profitable bee-keeping consists in adopting the hive and system of bee-management by which the greatest weight of comparatively small completed and most marketable supers can be obtained." I am sorry that your able correspondent makes such sweeping assertions. He would make it appear that the Stewarton hive is the acme of perfection, and that all other systems of management are defective. Our apiarian associations are working hard to introduce the bar-frame hive and the American slinger. Some two or three years ago one high up in the bar-frame school said the best way to assist cottagers would be to let a slinger be placed in every parsonage for general use; then the honey could be obtained without the destruction of combs. This notion is not at all in harmony with that of our Renfrewshire friend, who asserts that profitable management consists in adopting the hive and system which gives the greatest weight of small supers. This may be his opinion, but surely other folk may be allowed to think differently. We have had a honey fair annually in Wrexham from time immemorial, and many generations will come and go before small supers will take the place of honey jars in that market. Ever since I was born a hundred times more run honey has been consumed in this country than honeycomb, and for many future generations the probability is great that fifty times more run honey will be wanted than honeycomb. The Stewarton hive is adopted and adapted for supering, and I have not been slow to commend it for that purpose; but other kinds of hives serve their day and generation and their day is not over, and, if I am permitted to prophesy, I would say will never be over while bees are kept for profit. The great bulk of my customers for honey want it in a run state; they give good prices for it, and want more every season. I and hundreds besides keep bees for profit, and we are quite satisfied with our hives and systems. Our hives will bear comparison with other kinds of hives as to cost, convenience, and results. In 1868 our Renfrewshire friend had glorious results in supers from a Stewarton hive. The results same year from a straw hive in an adjoining county (Lanark) were equally good—viz., 328 lbs. gross. Mr. Briscoe has taken 56 lbs. of super honey from a Stewarton hive this year, and "H. J." another correspondent of this Journal, has taken 54 lbs. of super honey from a standard bar-framer of black bees.

In penning these notes my object is to help the readers of the Journal to form a right and safe conception of successful bee-keeping, and thus induce them to lay a good foundation this autumn for success next year and to expect good results from strong stocks of every description. The shape and materials of hives are of far less importance than their size and strength. All kinds of hives can be worked either on the swarming or non-swarming principle, and all kinds of hives can be either supered or nadired. If I were to adopt the Stewarton principle of supering, which is a good one, I would use my present straw hives slightly modified in their crowns, and never dream or have occasion to dream of their inferiority. I am not an admirer of bar-frame hives, but if I used them and wanted to work out the Stewarton principle I would not cast them aside, but use them with tiers of supers and removing the crown boards. I am now preparing my stocks for next year's campaign by having a large young effective force in every hive. Strong stocks, like healthy children, need less care than weakly ones. When bees from condemned hives cannot be obtained for strengthening stocks we resort to artificial feeding with a view to get a batch of brood in August or September. Strong stocks in any kind of hives make strong bee-masters. The satisfaction of success one year gives stimulus and strength for future work. Every favourable season for honey we have records of astounding results from strong hives, and we have reasons for expecting greater things in the future than we have had in the past.

Since the above was written a working man and his wife have been here seeking information. They have eight large hives pretty well filled; three of them have old queens three years old, certain to die next year. Several questions about supering led me to ask him how much he got for his run honey. He said 1s. 4d. per lb. I advised him to get all the run honey he could from his bees and sell it at that price.—A. PETTIGREW.

STEWARTON HIVES.

ABSENCE from home has prevented me from giving an earlier reply to the inquiries of "H. J.," relative to the management of Stewarton hives. Full instructions have appeared in the pages of the *Journal of Horticulture* more than once from the pen of "A RENFREWSHIRE BEE-KEEPER."

A strong Stewarton hive in full work requires three stock boxes, and two will not accommodate the bees sufficiently to prevent swarming and keep the queen out of the supers. Before winter

one or two of the lower boxes are removed, according to the strength of the colony. Last winter out of three stocks one retained two boxes, and the others not being so populous each passed the winter in a single box. In all cases the upper box has been the winter domicile. Driving is not required. As the autumn advances the bees retire into the upper chambers, and the lower ones are simply removed, carefully wrapped up to exclude moths, and are restored to the bees when the warmth of advancing spring enables them advantageously to occupy a larger mansion.—J. E. BRISCOE, *Albrighton, Wolverhampton.*

OUR LETTER BOX.

AMERICAN BEE JOURNAL (W. H.).—Apply to Messrs. Trübner & Co., Ludgate Hill, London.

A STEWARTON HIVE—DRIVING BEES (E. S.).—The swarm which you put into a Stewarton hive at the end of May has either been a small one or in some way mismanaged, seeing it has filled one box only. A bit of guide comb would have prevented the bees making their combs across the bars. You should not have filled the grooves of the bottom box, or in any box, with beeswax. The grooves are meant for use, and when filled with wax the slides could not be used. Your better way now will be to let the bees remain where they are; you will gain nothing by driving them into another hive. If they have not food enough for winter put a nadir (that is, one of the empty boxes) below the hive and feed them. By placing a dish or trough on the board inside the empty hive, with chips of wood in it, you will be able to feed the bees easily. Bees are driven from one hive to another by simply turning the full one on its crown, placing an empty one over it, tying a cloth round the junction, and drumming on the bottom or full hive for twenty minutes.

REMARKS.

- 4th.—Very hazy morning and a close warm day.
 - 5th.—Hazy morning, a little sunshine about 10 A.M., afterwards slightly foggy; slight shower about noon; dull afternoon.
 - 6th.—Dull morning, fine about 11 A.M.; afternoon bright and sunny; fine evening.
 - 7th.—Fine bright day.
 - 8th.—A somewhat dull and showery day, although there was occasional sunshine.
 - 9th.—Slight shower in morning, but on the whole a fair day.
 - 10th.—Fine bright day throughout.
- Barometer readings higher than those of last week. Shade temperatures mostly above, though the minimums were a trifle lower than last week. Very little rain.—G. J. SYMONS.

COVENT GARDEN MARKET.—SEPTEMBER 11.

TRADE and supply much the same as last week, consequently prices remain unaltered.

From observations taken near London during forty-three years, the average day temperature of the week is 66.8°; and its night temperature 45.3°.

TOMATO CULTURE.

THE Tomato is a vegetable which is not grown by every person who has a garden, because there are many persons who do not know how to use it, and others, again, think it difficult to cultivate. The first obstacle may easily be overcome, as full directions as to the best way of using this wholesome vegetable may be learned out of any shilling cookery book, and as to the culture of the plants, that too is simple. They may be grown in two ways—i.e., under glass and in the open air. In cold districts some seasons they do not succeed very well out of doors, but this is often more the fault of the cultivator than the tenderness of the plant.

In raising young plants some propagate them from cuttings, others from seed. Both ways may be successfully practised. Now is a good time to take cuttings from old plants. Place six or eight of them in a 6-inch pot, root them in a gentle heat, and afterwards keep them closely pinched in, but growing in a moderate temperature until about the new year, when they may be potted off singly and allowed to grow to form early fruiting plants. This is an excellent plan of retaining a good stock and securing early fruit in a simple way. Plants treated like this and properly cared for will produce fruit throughout the whole season. We are cutting fruit from plants now that were bearing in the month of April. These were raised from seed sown about February 1st.

Where plants are raised from seed sown early in spring for fruiting during the summer and autumn they should be treated at first like tender annuals as regards temperature, and their after requirements are simple. They will grow almost without care, but it is when they are just arriving at a fruit-bearing condition that they require attention. When the plants are allowed to grow as they like and make as much wood as possible they will never bear well. If they are to have a fair chance of fruiting they must be very closely pinched-in. This applies to their culture at all times and in all places; it is indeed the mainspring to success. We have plants now bearing two and three dozen fruits planted out against a south wall, and there is hardly an inch of growth on them that is not bearing fruit. Had they been allowed to ramble about, in all probability we should not have secured a single fruit. From the time the first fruit is formed we begin cutting off the side shoots, and ever afterwards they are kept closely cut-in to the bunches of flowers. When plenty of fruit sets on the main stem we prefer growing them with a single stem, allowing no side branches to grow; but when side growths are allowed they are cut in similarly to pinching the main stem.

Our crop of Tomatoes in pots has been the subject of general remark this season, and yet we have only three pots of them. They are growing against the back wall of a cool vinery, and each plant covers a space of about 12 square feet. Many side shoots have been taken from the centre one, but all of them have been pinched-in to the flowers, sometimes nothing but the flowers being left on

the stems, and in this way each plant in a 12-inch pot has produced about a hundred fruits. This I consider a profitable crop, as nothing else would have come to maturity on the back wall under the shade of the Vines. When grown in pots the plants should be potted in a rich mixture of about half loam and half cow dung. Some object to growing Tomatoes in rich soil, thinking it makes them run too much to wood. It does make them do this, but a succession of fine fruit cannot be secured unless there is some good stuff at the roots to produce them, and overluxuriance can always be checked by cutting off the shoots and throwing the strength into the fruit. Strong doses of liquid manure should also be given those in pots. In the open air they should be planted in moderately rich soil, and here they may also be given manure water about this time as the crop demands considerable nourishment. We have grown Tomatoes in pots trained to a single stake, but this is not such a profitable way of cultivating as that above indicated.

Out of doors there are generally many green Tomatoes which fail to colour before the plants are cut down by the frost: all such should be cut off with the stems attached, and if they are hung up in a dry room or warm glass house they will ripen and give a supply of fruit throughout the winter.—A KITCHEN GARDENER.

OBJECTS OF HORTICULTURAL INTEREST IN AND NEAR PARIS.

Now that the principal shows in England are mostly over many of the gardening community will doubtless be wending their way to Paris to see the department of horticulture in connection with the Exposition at the Trocadéro, and especially the exhibition of fruits, which opened on the 16th inst. and continues until the middle of October; and as all may not know the additional points and places of interest horticulturally worth seeing, we subjoin a list of some of the more important.

The Jardin des Plantes, south of the Seine in an easterly direction beyond the Halles-aux-Vins, in addition to containing the best-arranged botanical garden in Europe, has excellent botanical, mineralogical, and anthropological museums. There is a good collection of Pears, and the official and economic plants are very interesting. Visitors will find Professor Decaisne, M. Albert, jardinier-en-chef, and the staff most courteous to English horticulturists; and pages might be written about the advantages furnished, almost gratuitously, to students of science and natural history of all nations from this mine of information, and few know what obligations foreigners are under in this respect to the liberality of the French nation. The garden may be reached by omnibus.

The Jardin d'Acclimatation in the Bois de Boulogne, beyond the Arc de l'Etoile, contains much that will interest the horticulturist; and among the objects is a large test collection of Vines planted in the open.

The Jardin de la Ville de Paris at La Muette, beyond the Trocadéro, is a vast manufactory and store for plants used at the municipal entertainments and in the decoration of

most of the parks, public gardens, and squares of Paris, but is more worthy of a visit in the winter or early spring; here about two million of plants are annually raised.

The Jardin du Luxembourg attached to the Palace south of the Seine is well kept, and in the borders are some showy perennials. There is also a fair collection of Roses, originally commenced, I believe, by M. Laffay, some good specimens of trained fruit trees, an apiary, and the head-quarters of an apiarian society. M. Jolibois is jardinier-en-chef.

The Tuileries gardens, so centrally situated, will irresistibly lead the visitor to the Champs Elysées. Their cosmopolitan assembly and the Bois de Boulogne are all too well known and conspicuous to need any description here.

The Parc de Monceaux, near the Boulevards Hausmann and Malesherbes, and a favourite lounge of the Parisians especially on fête days and holidays, may be reached on the return from the Bois, and, notwithstanding a few palpable eyesores, good taste prevails, and it has been truly styled the prettiest little park in Europe.

The Parc des Buttes Chaumont, formed out of the old gypsum quarries near La Villette and within the eastern barrier, is very pretty and well kept, and will repay a visit. Some fine views of Paris are here attainable. The Parc de Vincennes, reached either by water or rail, may also be visited if time permits.

The cemetery of Père-la-Chaise in the extreme east of the city will not repay the traveller either by its beauty or its horticulture.

Versailles, with its magnificent grounds and its Grand and Petit Trianon, should be taken if possible on a day when the fountains play, and this is usually on a Sunday. A similar occasion should be selected for St. Cloud and the fine-timbered park separating it from the great national fiddle museum and manufactory at Sevres. These may be reached either by water, rail, or tramway, but the undulating and well-wooded banks of the Seine are so pretty in this direction that most will prefer the water at least one way.

The gardens attached to the Louvre, the Palais Royal, and adjoining the Chapelle Expiatoire in the Boulevard Hausmann, and many others in the various squares in different parts of the city, are well kept, and constitute cool and pretty lounges.

Not the least interesting point for horticulturists, perhaps one of the most remarkable on the Continent, is the great central market or Les Halles, which, in addition to an omnium gatherum of all comestibles, has a division devoted to fruits, flowers, and vegetables on a much more extensive scale than anything of the kind to be found in London. In addition the following are good fruit and vegetable markets:—The Marché St. Honoré near the Rue St. Honoré, the Marché de la Madeleine in rear of the Church of the Madeleine. There are also several other fine and airy markets for vegetable produce in different parts of Paris. The flower markets on the Quai Napoleon, near Notre Dame, that on each side of the Madeleine, and those in the Place St. Sulpice, and at Chateau d'Eau are held on different days of the week, and in the two former an hour or two may be pleasantly and profitably spent.

The following trade horticultural establishments will offer more or less of attractions to travellers possessed of gardening tastes—viz., the nurseries of E. Verdier, fils aîné, 37, Rue Clisson, and C. Verdier, fils, 28, Rue Baudrimont, both in the twelfth arrondissement, and near the Jardin des Plantes; and that of M. Levêque et fils at Ivry-sur-Seine, each celebrated for the production of new Roses. Roses for forcing are also largely grown by M. Jamain at Les Glacières, between the Portes d'Orléans and de Fontainebleau. The finest exotics and the most exquisite bouquets and cut flowers will be found in the shops of Madame Scogard, Rue Faubourg St. Honoré; Maison Debrie, 12, Rue Neuve des Capucines; Vaillant-Roseau at 41, and Labrousse at 12, Boulevard des Capucines; and Bourgeau, 6, Place de la Madeleine.

Nearly all the great seed establishments, including those of Messrs. Vilmorin, Andrieux, & Co.; Paul Tollard and Loise Chauvière, are situated on the Quai de la Mégisserie, east of the Louvre, and in the same locality are some good shops where nearly every variety of horticultural tools and sundries in use on the Continent may be obtained. Notable are those of Allés frères, L. Francin, C. Boret, and Maison au Forge de Vulcain. In some of these shops a good deal may be learned, although the tools and appliances are not all advances upon those in use in this country. In the same quarter, along the north bank of the Seine, during the planting season a

large amount of nursery stock is on certain days of the week pitched for sale, and during seasons of cold drying east winds often appears anything but a successful venture for intending planters.

Primeurs will be found as early, as fine, and expensive as anywhere in Europe at M. Chevet's in the Palais Royale, at Potel & Chabot's, Boulevard des Italiens, and at M. Joret's, 16, Place du Marché St. Honoré, and in the Boulevard des Capucines next the Grand Hotel. Curious seeds and Algerian and colonial produce may be seen and obtained at Maison à la Ville de Marseilles, 158, Rue de Rivoli, and of M. Hediard, 21, Place de la Madeleine.

In the suburbs Mushrooms are grown largely at Montrouge, outside the Porte d'Orléans. At Bourg-la-Reine, in the same direction, is the nursery of MM. Jamin & Durand, where the finest possible specimens of training and pruning of fruit trees will be found. M. Margottin fils, well known as a rosierist and grower of Grapes, has also an establishment here. At Sceaux are the nurseries of MM. Thibaut & Keteleer, Croux et fils (Vallé d'Aulnay), and L. Paillet, all worth visiting, and in the same locality at Fontenay-aux-Roses large numbers of Roses are grown for market. Brie-Comte-Robert, also famous for its Roses, is best reached by rail from the station in the Place de la Bastille; but the great Rose centre is at Grisy-Suisnes, about two leagues south, and approached by an omnibus, which runs daily from Brie station to Grisy-Suisnes, where are situated the Rose nurseries of MM. Scipion Cochet, Grainger, L. Cochet, Carré, and many others. English rosarians will be struck with the numberless patches of Roses, varying in size from a rood to a couple of acres, in the open fields and entirely unprotected, the result being the production of clean and healthy-looking but not over-vigorous stuff.

A large amount of fine vegetables is grown both within and without the fortifications, especially towards the east of Paris, and passengers alighting at the Bel Air station of the Paris Ceinture Railway during certain seasons of the year will see some acres covered with cloches used for Lettuces, Cucumbers, various salads, Cauliflowers, &c. In a north-westerly direction, accessible by rail from the St. Lazare station, is Argenteuil, where fine Asparagus, Figs, Strawberries, and Vines are chiefly grown, but not altogether according to English ideas.

There are many other horticultural haunts and objects within reach of Paris, notably the establishment of M. Rose-Charneau at Thomery, but time and space prevent further reference for the present. A passport and politeness will be found useful, and the usual introductions to the museums and most of the public places above alluded to.—T. LAXTON, Bedford.

BULBOUS PLANTS FOR WINTER AND SPRING DECORATION.

Narcissuses.—Next to the Hyacinth in point of elegance and fragrance comes the Narcissus. Its erect and lofty heads are admirably suited for intermingling with other spring flowers, and it has the further advantage of remaining a long time in bloom. The treatment recommended for the Hyacinth will meet precisely the requirements of the Narcissus, only that in potting the latter the bulbs should be buried in the soil right up to the necks. Three bulbs may be placed in a 32-sized or 6-inch pot, and single bulbs can be potted in large 60's or 48's; for decorative purposes both sizes are very suitable. Where large quantities of both these and Tulips are grown for home decoration the bulbs are oftentimes planted thickly together in boxes to grow and show their flowers when they are lifted, and placed in pots as required; but to those who wish to grow a few, and to excel in growing them, it is preferable to proceed as directed last week for growing Hyacinths. Many Narcissuses are admirably adapted for early forcing, especially the Double Roman and Paper White varieties. Other attractive and desirable sorts are Bazelman Major, Grand Monarque, Grand Pimo Citronier, Newton, Queen of the Netherlands, and States General. Jonquils, both the double and single varieties, are sweet-scented and attractive, but perhaps are not so suitable for forcing as the Polyanthus Narcissus, yet if potted in the manner described and allowed to grow naturally until the days lengthen they are very beautiful, and do not become drawn and lanky.

Crocuses, that pretty "harbinger of spring," one of the first flowers of our borders, an ever-welcome visitor, may be grown successfully in pots, and few plants can equal the brightness and purity of the colours of blue, yellow, and white represented by the Crocus. Crocuses, like Narcissuses, are some-

what impatient of a close confined atmosphere, and therefore must have abundance of air after they are removed from the plunging material, and must be placed near the glass while advancing into bloom. Albion, Bride of Abydos, Garibaldi, Golden Yellow, Mont Blanc, and Sir John Franklin are cheap and reliable varieties. The soil that suits them is the same as that recommended for the Hyacinth, but care must be taken that plenty of drainage is given, for Crocuses have a great dislike to soddened soil. Place as many corms of each variety as can be conveniently placed together in a 6-inch pot, cover over with soil, and plunge them under a covering of cocoa-nut fibre. Allow them to remain there until they have fairly started into growth and have filled the pots with roots, when they should be removed either to a cool frame or to a shelf in the greenhouse. A temperature of 45° to 50° after this will be sufficient to excite them to bloom, for if placed in a strong heat the flowers are apt to perish, and the foliage to increase in length and luxuriance.

Snowdrops.—The modest-looking Snowdrops should not be overlooked if variety is desired; but they bloom at such an early period naturally that it is only necessary to pot patches from the open ground where such can be readily procured. These should be plunged for a time like the Crocuses, and then be removed to a shelf or cold frame to expand their flowers.

Lachenalias.—The varieties pendula, tricolor, and versicolor are not grown so extensively as their beauty and adaptabilities entitle them. Their treatment is so simple, and they increase so rapidly, that the smallest greenhouse should not be without them. Mr. Ollerhead succeeds admirably with them grown in baskets simply filled with moss. As many bulbs as can be conveniently placed within the moss are employed, and when water is required the basket is dipped in a tank. By this treatment each basket becomes a globe of bright flowers, and its beauty and simplicity are almost beyond imagination. The plants also succeed admirably potted in the usual way and placed on shelves near the glass. The true variety of pendula is undoubtedly the best for pots and general decorative purposes. Not a day's unnecessary delay should be permitted in procuring and potting bulbs of these distinct and attractive spring-flowering plants.

Ixias, Sparaxis, and Tritonias all require similar treatment, and succeed well potted and placed on the shelf of a cold greenhouse. Their miniature Gladiolus-like spikes of bloom are both curious and attractive. Some of the best Ixias are grown in the Channel Islands.

Scillas bifolia, hyacinthoides, and sibirica are charming little greenhouse plants, and will flower beautifully in pots if left to come away in a steady and natural manner; so also will *Triteilea uniflora*. The bulbs should be placed thickly together in the pots.

Hyacinths, Tulips, Polyanthus Narcissus, and Crocuses are no doubt the most cultivated of the different selections given, but where there is room and variety wanted the others are all worthy of a good trial. The greatest secret no doubt in growing all of them well is allowing them to become established well at the root before subjecting them to a high temperature. Have a mixture of good staple soil as recommended, follow out the directions given as to potting, cover them with cocoa-nut fibre, and leave them to Nature for at least six weeks, and they will emit healthy and strong roots; then with an established foundation to work upon forcing may be successfully accomplished. The earlier flowers are wanted so correspondingly early must be the preparations for successfully producing them, but at no time subject any of them to a higher temperature than circumstances require.—J. W. MOORMAN.

DRESSING CARNATIONS.

YOUR correspondent "WYLD SAVAGE" writes rather wild, or wide of the mark, in his notes on this subject. He asks the question whether it is right and proper to dress Carnations? I reply, As the florist dresses them it is; as "WYLD SAVAGE" defines dressing them it is not. He implies in his remarks that gum is used. I can assure your readers that it is never used. Then he would lead your readers to believe that the cards hold the calyx like a vice—firmly. It is not so; the hole in the centre of the cards is so large that it does not touch the calyx. The object in using the cards is to show the flowers off to the best advantage, as is done with Asters, Zinnias, and similar flowers. Carnations, Picotees, and Pinks are not the only flowers that are dressed; the Chrysanthe-

mum and some other flowers owe more to the dresser's arts than they do. "WYLD SAVAGE" also asks how is it that "we rosarians" do not dress our flowers. I answer, Simply because it is unnecessary. If it were we should find "WYLD SAVAGE" doing it I have no doubt. If he has seen a Carnation so altered by dressing that he could not recognise it I have not.—J. DOUGLAS.

THE COMING INTERNATIONAL SHOW.

WE have received the following suggestive letter relative to the Great Exhibition proposed to be held in London in 1880. Practical suggestions made now are much more likely to be of value than grumbings after the event; we therefore readily publish the letter as containing hints worthy of consideration. We may remark, however, that at the last Great International held in 1866 there were many classes specially provided for growers of limited collections of plants, in the manner suggested by our correspondent:—

"Would it not be well if the Committee of the coming International Horticultural Exhibition were to issue a schedule at once, so as to give intending exhibitors an opportunity to prepare creditable examples for the occasion? It is not necessary that the prizes be affixed; we only want to know at present what is to be asked for.

"Again, it is to be hoped that the trade and private growers may be kept separate in everything, as many amateurs object (and with good reason) to enter the list against the trade; neither is it politic on the part of the trade to show against amateurs. It is submitted also that classes should be made in such a manner that those who are extensive growers shall compete amongst themselves, and those with more limited means and space be likely to meet with those only of their own calibre. Thus if a collection of, say, thirty plants is asked for, let there be also collections of the same for, say, twenty and twelve, and prohibit the same exhibitor from showing in more than one of the collections; this will allow the man who can only muster twelve to meet a friend in the same condition. The "big" men will have gone into the twenty or thirty.

"There should also be a definite number of specimens stated in each class, it being far more satisfactory to exhibitors and far easier for Judges when such is the case. For example, if a collection of Crotons, Alocasias, Anthuriums, Dracenas, &c., be asked for there should be in every instance a given number stated.

"If a collection of herbaceous plants are asked for, let it be stated if bulbs are to be included or excluded; and also let it be clearly stated what is to be the understanding or reading of the word 'hardy.' (1878-79)

"In classes for Tree Ferns it should be clearly stated that the stems should not be under a given height. In collections of exotic Ferns where Tree Ferns are excluded it should be stated if any Ferns without a stem may be exhibited, because a very fine example of *Cyathea medullaris* or *Dicksonia antarctica* could be shown without their having the slightest stem. In the case of a pair of Tree Ferns are we to understand they should be of the same species, or otherwise?

"A preliminary schedule issued as soon as possible, the stipulations being made clear and explicit, would be of great value to exhibitors, and would contribute materially to the completeness and grandeur of the show.—EXHIBITOR."

BORDER BEDDING DESIGN.

Now, when gardeners and proprietors are considering desirable combinations of flowers for the coming year, the following very effective arrangement of lines for an undulating flower border, forming the southern boundary of the pleasure ground at Minella House, may be usefully noted:—

The border is about 60 yards long, and facing north. The background is planted with evergreens, many of the shrubs being very rare, and all striking. Sloping from them and filling interstices between are perennials carefully selected; while gracefully arranged, according to their respective heights and colours, are four lines:—1, And next the margin of the walk, blue *Lobelia* alternately with the *Manglesi Geranium*. The flowers of the latter rise above and contrast remarkably with the former, seen from either end. On nearer approach the variegated leaves of the *Geranium* render more vivid the taste of the arrangement. 2, The shrubby yellow *Calceolaria Aurea floribunda*, still in contrast and gradually rising higher.

3, Henderson's Dark Red Beet; foliage bright, glossy, and brilliant; higher. 4, Tall pink Geraniums; handsome foliage, and reaching upwards to meet the perennials and shrubs already indicated, the whole forming a border that may be well imitated, but can hardly be surpassed.—W. J. M., *Clonmel*.

PEAR AUGUSTE JURIE.

A PEAR ripening at the same time as Beurré Giffard, and far superior to it in size and in flavour, is a great acquisition to the number of August Pears. Our figures were taken from specimens grown in the garden of the Royal Horticultural Society at Chiswick, where they were produced on an open pyramid, and where the fruit ripened to perfection this season from the 10th to the 12th of August.

The fruit is about medium size, roundish ovate, even and regular in its outline. Skin green, becoming yellowish green

always died off. The same with cuttings taken at this time of year and grown into strong plants before the beginning of winter. I have tried them in the warm Cucumber house, in cold frames, on the front shelf of a greenhouse, and on the back shelf of a half-span, always with the same result—viz., that in April I have not one left, and have to buy in a fresh lot for bedding.—H. R. C.

[H. R. C.'s] difficulty is not an uncommon one, and the reason is not far to seek. Nearly all are guilty, nurserymen included, of starving Verbenas through the winter, keeping a dozen, or even a score, store plants in a pit where there only ought to be one. They become as hard as sticks under that treatment, and are more likely to drag their existence through the subsequent barbarous treatment generally thought good enough for them—viz., being perched on a top shelf in a dry and draughty house where the fluctuations of temperature and other conditions are nearly as great as it is possible to have them in winter. It is true that those which do survive this treatment grow and produce cuttings when put under liberal treatment in spring; but can any rational man suppose their progeny can have as good a constitution as if the stock plants had been treated liberally throughout? No; if you want Verbenas to grow and produce such a display in summer and autumn as Verbenas should do, you must have cuttings from a healthy stock—rather a rarity I admit, but still existent—and treat them like growing plants all through the winter, say like herbaceous Calceolarias or Primulas, excepting that they must not be shaded at all after they are struck.

My cuttings are just rooted, and they will now be transferred to boxes where each plant will have at least 4 inches of room each way and as much in depth of soil. They will be kept just slowly moving all winter; you cannot keep such plants dormant without injuring them. I know of an instance this season where a gardener who wintered his plants on the ordinary starving system, being short of stock, begged a few cuttings from a neighbour who had kept his plants in the way I recommend, and the difference in the beds is very marked, so much so that the progeny of the liberally treated plants, although they are the same varieties as the starvelings, are taken to be distinct from them.

It is rather late now, but cuttings may still be taken from a healthy source. They should be inserted quite 2 inches apart in the pots or boxes, and allowed to remain in them till February. A little decayed manure should be mixed with the soil in the lower part of the pots, placing lighter sandy soil on the top, which will encourage them to

root quickly, and the richer soil will afterwards support them better. A gentle dungeb would be best to strike them in at this late season, gradually hardening them off afterwards as soon as rooted. They do not like much fire heat.

As "H. R. C." can manage all other ordinary bedding plants I trust these hints will be sufficient. There is nothing better than sulphur for curing mildew if the sulphur can be obtained good. The best for the purpose has a bright glowing look and feels harsh to the touch; that which feels soft and smooth is useless, you should be able to feel and hear it crunch. The sun ought to shine on it after it is applied, and the destruction of the mildew will be speedy.—WM. TAYLOR.]

SEDUM SPECTABILE.

Of all the flowers which I grow in my garden I have found none so alluring to diurnal insects as this beautiful autumn-flowering Sedum. I have a considerable quantity of it planted in clumps of threes; they form thus a large head of bloom, and I have counted on one of these clumps upwards of a score of humble bees of different species; the hive bee, too, seems fond of it, but not so fond as of the Mignonette near at hand. But besides I have seen on it at one time the following diurnal Lepidoptera:—Red Admiral (*Vanessa Atalanta*), Small Tortoiseshell (*Vanessa Urtica*), Painted Lady (*Cynthia Cardui*), Peacock (*Vanessa Io*), Brimstone (*Gonepteryx Rhamni*), Com-

Fig. 35.—Auguste Jurie Pear.

as it ripens, with a thin speckled coat of russet on the side next the sun, and otherwise marked with russet patches. Eye closed with tooth-like segments and set even with the surface. Stalk from 1 to 1½ inch long, inserted without depression. Flesh crisp, rather granular, sweet and briskly flavoured with a fine Melon perfume.

This is a valuable early dessert Pear, ripe in the second week of August.

This was raised from Beurré Giffard at the Ecole d'Horticulture, Ecully, near Lyons, which is under the able direction of our friend M. Willermoz, and was named in honour of M. Auguste Jurie, President of the Horticultural Society of the Rhone. It first ripened fruit on the 11th of August, 1851, and was described by Abbé D. Dupuy of Auch in "L'Abeille Pomo-logique" for 1863. As described by Abbé Dupuy it is bright red on the side next the sun, which is, no doubt, attributable to the climate of the south of France, for here we have found no trace of red upon it, though we have seen it with a slight orange tinge on the exposed side.

WINTERING VERBENAS.

I CAN manage all ordinary decorative plants, but Verbenas always beat me. I have tried taking up the old plants, but they have always been covered with mildew, and in spite of keeping them dry and dressing them with sulphur they have

mon Cabbage White (*Pieris Brassicæ*), Small Cabbage White (*Pieris Rapæ*), and Common Copper (*Lycæna Phlæa*). I have not noticed that the nocturnal Lepidoptera affect it, but it is very pleasant to anyone fond of seeing living creatures enjoy themselves to see how the above insects seem to rejoice in this pretty plant.—D., *Deal*.

NEWCASTLE BOTANICAL AND HORTICULTURAL SOCIETY.

AUTUMN SHOW, SEPTEMBER 10TH AND 11TH.

So remarkable have been the successes achieved at the several shows of this rejuvenated Society during the past few years that the last Exhibition, now under notice, was anticipated with more than ordinary interest—not by local exhibitors merely, but by horticulturists and cultivators in various parts of the country. We have the pleasure to record that the last success has proved more remarkable than ever. A fact that is peculiarly gratifying in connection with the Show is that every exhibit entered was staged, and when it is stated that there were 888 entries made by 158 exhibitors the circumstance noted is something for the Society to be proud of. The 158 exhibitors at this Show have done honour to themselves and set an admirable example to others, and we cordially congratulate the Society on having such an earnest body of supporters.

Under the most fortuitous circumstances the success of any show depends in a great measure on the perseverance, tact, energy, and exertions of the Executive Committee and Secretaries. That none of the Newcastle officials lack in these essentials is obvious, for in the space of a little more than two years they have raised their exhibitions from a commonplace local character to a position which justifies them being ranked amongst the best of provincial shows. Formerly competitors were confined to a limited radius, but now exhibitors of renowned repute enter from all parts of England, and even the "land o' cakes" adds its quota likewise.

The Show just held both in extent and quality of produce surpassed the most sanguine expectations. In consequence of the average high quality of the productions many worthy exhibits did not receive the Judges' awards. This may cause temporary disappointment, but the result will be to develop further and more indomitable energy in the future. Those who were successful were not humiliated, and future honours are well within their reach. They have only to increase their exertions, and in due time they will have their reward. Plants have hitherto formed an important element in the Society's autumn Show; this time the classes for them were very limited. The Committee acted judiciously in so doing. Summer is the time for plants—autumn for fruit, cut flowers, and table decorations. The Show of fruit was superb, and it was no easy task for the Judge to make his awards. The table decorations of vases, epergnes, &c., were a splendid feature of the Exhibition; and florists' flowers, especially Dahlias, well sustained the fame of northern florists. Table decorations, fruit, and florists' flowers were arranged in the Corn Exchange, which was tastefully decorated with banners and mottoes. The bouquets, flower baskets, and epergnes were in the Town Hall adjoining.

In Class I five prizes were provided for the most tastefully arranged table with flowers, plants, and fruit. There were seven competitors, and the tables extending the entire length of the room produced a magnificent effect. The first prize of £10 was well won by Mr. Cypher of Cheltenham with a table which had for its centre a beautiful plant of *Cocos Weddelliana* in a bed of *Selaginella* and Ferns, and containing also Orchids, white and red *Lapagerias*, and several fine Grasses. Encircling the base of the *Cocos* were four glass quadrants and four horseshoe-shaped glasses artistically filled with flowers; besides these were two end pieces, fourteen finger glasses, and twelve dishes of fruit. The end pieces had bases of *Dipladenias*, *Allamandas*, and *Ixoras*, and lighter-coloured flowers were employed in the tops. This table altogether was a model of lightness and artistic skill. The second, third, and fourth tables were very near to each other in point of merit, the third being also very effective. Mr. Moul, Ravensworth Castle; Mr. Methven, gardener to J. Lange, Esq., Heathfield House; and Mr. Robinson, gardener to C. Perkins, Esq., Kirkley Hall, were the respective winners.

Table plants were numerous and good. Mr. Westcott, Raby Castle, won first honours with neat examples of *Dracænas*, *Crotons*, and *Aralias*, beautifully surfaced with a *Selaginella*; Mr. Cypher and Mr. Lazenby, Woodside, Darlington, securing second and third prizes. Vases, epergnes, and bouquets were a fine display and occupied the attention of the Judges for a considerable time. For epergnes for the drawing-room, Messrs. Cypher, Bradley, Jones, and Hynes secured the prizes in the order named amongst eight competitors. Mr. Cypher was also first in the class for bridal bouquets; Messrs. Turner Brothers, Liverpool; J. Jones, Sunderland; and Mrs. Crament, Sunderland, had the remaining prizes. Twelve hand bouquets were staged; Mrs. Crament was first, and Mr. Cypher second. They were both very near to each other in point of merit, and far in advance of all

others. Mr. Cypher was first for a bridal bouquet, and Messrs. Turner Brothers second. Baskets of cut flowers were shown extensively, Mr. Davison securing the first position; and button-hole bouquets were very numerous. Mr. J. Battensby having the first prize with an arrangement of *Hoya bella*, *Bouvardia*, *Myosotis*, and *Maidenhair Fern*.

FRUIT.—This formed the most important feature of the Show, the Society's prize of £5 for eight dishes of fruit, distinct, black and white Grapes being allowed, brought out seven competitors, the first prize going to Mr. J. B. Jowsey, gardener to Gilpin Brown, Esq., Richmond, who staged fine *Gros Guillaume*, and *Muscat of Alexandria* Grapes scarcely ripe; *Royal George* Peaches, very good; and *Violette Hâtive* Nectarines; an *Enville Pine*, the top of which was scarcely ripe, whilst the bottom was too much so; a dish of Plums containing three varieties, apparently Jefferson's, Kirke's, and *Victoria*; a good dish of *Brown Ischia* Figs, and a small Melon too ripe. Mr. Westcott, Raby Castle, was placed second with *Muscat of Alexandria* and *Black Hamburgh* Grapes, both being fine in colour and finish; *Barrington* Peaches, *Pitmaston Orange* Nectarines, both very fine; a splendid *Queen Emma Melon*, *Providence Pine* with a plural crown, rather stumpy, and imperfect in shape, but quite ripe; *Moor Park* Apricots, and the *Raby Castle Fig*. Mr. Ingram of Alnwick Castle was third with an excellent *Queen Pine*; *Black Hamburgh* and *Muscat of Alexandria* Grapes, both very good; *Golden Queen Melon*, *Barrington* Peaches, *Pine Apple* Nectarines, and *Jargonelle* Pears. We have been particular in describing the three collections. Great care and scrutiny was exercised by one of the best judges of fruit in England, yet, nevertheless, many other good judges thought that in consideration of the not ripe *Muscat* Grapes, and the slight comparative value of *Gros Guillaume* for flavour, and the imperfectly ripened *Pine* and *Melon*, that the first collection was not really the best. The fact is, in a Show of such magnitude the labour was too great for one Judge, who could not fail being fatigued, and in that state no man can properly discharge duties so important.

For six dishes of hardy fruit (*Peaches*, *Nectarines*, and *Apricots* excluded), Mr. Shaw, Blackbrook, was first with *Williams' Bon Chrétien* Pears, *Prune Damsons*, *Hawthornden Apples*, *Golden Drop* Plums, *Cob Nuts*, and *Red Grape Currants*. Mr. Westcott was second with *Golden Pippin* Apples, *Red Currants*, *Morello Cherries*, *Washington Plums*, *Williams' Bon Chrétien* Pears, and *Raspberries*; and Mr. Brogden, Jesmond, third; all the collections being good.

For six bunches of Grapes, in not less than three varieties, Mr. Westcott was first with *Muscat of Alexandria* (fine berries), *Gros Guillaume*, *Bowood Muscat*, *Golden Queen*, and *Gros Colman*, all very fine in colour, size of bunch and berries. Mr. Hammond, gardener to Sir Wilfrid Lawson, Bart., Brayton, was second with *Black Alicante* (very good), *Muscat of Alexandria*, *Lady Downe's*, and *Buckland Sweetwater*; Mr. Thompson securing third honours with creditable bunches. A very fine class. For two bunches of *Black Hamburghs* Mr. West, Mr. Jowsey, and Mr. Laidlaw were awarded the honours in the order named. The first were very fine, hammered, and good in size of bunch and berry; the second lacked size, and the third were rather loose. There were twelve competitors. For two bunches of *Black Alicante* there were nine competitors, the first being Mr. Hammond with even and well-coloured berries and fine bunches; Mr. Westcott was second, and Mr. Ingram third, all exhibiting well. For two bunches of black Grapes, any other kind, Mr. Jowsey was first with *Gros Guillaume*, very fine, cut from grafts on the *Black Hamburgh*; Mr. Ingram was placed second with Mrs. Pince not quite ripe, but very fine in bunch and berries; and Mr. Laidlaw third with *Gros Guillaume*. For two bunches of white Muscats Mr. Jowsey was again first with good bunches and very fine berries; Mr. Ingram and Mr. Bradley securing the second and third prizes with capital produce. For two bunches of *Buckland Sweetwater* Mr. Jowsey, Mr. Hammond, and Mr. Moul secured the prizes in the order named. The bunches of Mr. Hammond were larger, but not so well finished as those of Mr. Jowsey. For the two heaviest bunches of Grapes Mr. Laidlaw won first honours with *Gros Guillaume* weighing between 8 and 9 lbs.; and Mr. Witherspoon was second with *Calabrian Raisin* weighing 4 lbs. 10 ozs. For two bunches of white Grapes, any other sort, there were eight entries, Mr. Ingram being first with *Trebbiano*, a very fine bunch indeed; Mr. Hammond and Mr. Jowsey second and third respectively with *Calabrian Raisin* and *Foster's Seedling*. The show of Grapes was altogether excellent, and as a consequence many highly creditable bunches failed to secure prizes.

Six *Pine Apples* were staged, the first prize being easily secured by Mr. Ingram with a perfection of a *Queen* weighing 5 lbs. 5 ozs.; Mr. Moul and Mr. Brown being next in order of merit. There were twenty *Melons* exhibited, Mr. Brown being first with a fine-flavoured green-fleshed variety.

PEACHES AND NECTARINES.—Peaches were excellent, seventeen dishes of six fruits being staged. The first prize was secured by Mr. Laidlaw with richly coloured examples of *Royal George*, the second by Mr. Elsworth, Liverpool, with *Late Admirable*; third by Mr. Irvine, Whitburn, with *Royal George*. Altogether

the Peaches were remarkably fine. There were ten dishes of Nectarines, the first prize being secured by Mr. Elsworthy with Victoria, Mr. Crozier and Mr. Laidlaw being next in order of merit.

Apples were both numerous and good. There were eleven dishes of dessert Apples. Mr. C. Rylance was placed first, and Messrs. Oliver & Petty second. For kitchen Apples Mr. Rylance was again first, his Lord Suffields being very fine; Mr. Service was second with fine fruit of Eckinville, Tower of Glamis, and Withington. Dessert Pears were also excellent, the first prize for four varieties being secured by Mr. Metcalfe, Grantham, with Louise Bonne of Jersey, Beurré d'Amanlis, Williams' Bon Chrétien, and Thompson's. The prizes for Plums were won by Mr. Rylance, Mr. Service, and Mr. Ingram, all staging Jefferson's.

CUT FLOWERS.—Within a circle of some twenty miles around Newcastle, writes Mr. Witherspoon, perhaps we have the keenest growers and exhibitors of florist flowers to be found anywhere in the kingdom. To select a dozen names, all amateurs, is no enviable task, but the following "baker's dozen" can make a show in September anywhere that is worth going a long distance to see. The gentlemen named not only can grow flowers, but also all know them well, and woe betide the reputation of the judge who blunders. We have first Mr. Battensby of Blayden, a capital all-round grower; Mr. Brown of Fence Houses, much the same but on a smaller scale; Mr. Brown, Bedlington, noted for Dahlias; Mr. Codling of Meldon for Gladioli, Hollyhocks, and Roses; Mr. Fenwick, Netherwitton, famed for Gladioluses. As usual, his winning stand was superb, and his leading flower, Catherine Fenwick, a seedling, white with carmine flakes, well merited the certificate awarded; it is a flower of great substance and without a fault. Mr. Flowdy for Dahlias; the Messrs. Harland and Mr. Scott for Pinks, Picotees, and Carnations. The Brothers Harkness of Allendale with rapid strides are coming on, as also is Mr. Oliver, who on this occasion had a certificate for a very fine light Dahlia; Mr. Sanderson of Whorlton for Globe Asters (his stand was really grand). Next we have Mr. Sporr of Svalwell, also quite an enthusiast, and who especially does his Gladioli well; and next, Mr. Walker, the acknowledged northern amateur champion Dahlia grower. On this occasion this good cultivator, who works hard in the Gateshead railway shops every day, took equal first for twelve, second for six; and though he was only awarded third for twenty-four, there were many good judges, including Mr. Bosten of Bedale, who would have been satisfied had he been awarded first. To speak separately of the many exhibits at this great Show made by the above and other exhibitors is impossible, as will be obvious when it is stated that the cut flowers staged exceeded four thousand.

Valuable miscellaneous collections of plants, &c., were exhibited by Messrs. Clark Brothers, Watson, and Robson & Son, which contributed greatly to the interest of the Exhibition; and the skeleton leaves from Mrs. Hodgkin, Manchester, had hosts of admirers. The weather was brilliant, and the crowd of visitors immense. The Newcastle Show has more than sustained its reputation, and the able and indefatigable Hon. Secretaries, Messrs. Taylor and French, have won another triumph.

PROTECTING PEARS FROM BIRDS.

MEETING the other day a gentleman who is devoted to his garden, and works in it both with zeal and skill, we commenced talking about fruits and the fruit of this year—thence I mentioned the terrible destruction by the birds. My friend said, "I prevent all that mischief to the Pears by cutting a slit in a card the size of a playing card and passing the stalk of the Pear through the slit up to the middle of the card, forming, in fact, a sort of collar or Elizabethan ruff to the Pear; then the birds cannot reach the fruit to pick into it, and all is safe." The plan is ingenious, and may be adopted by amateurs in regard to their pyramid fruits. I had noticed that the Pears most frequently injured were those which had a convenient perch for the little predators just above the fruit, and that being wanting some escaped; but the card plan would cause the Pear to be perfectly protected from the piercing and destroying bill, as no bird can pick into fruit while it is on the wing or hovering—it must have a firm foothold, and then, having that, will work away; lacking it, it cannot reach the dainty, and must depart considerably disappointed.—WILTSHIRE RECTOR.

PERILLA ATROPURPUREA LACINIATA.

THIS is the first year I have grown this dark-foliaged plant, and I must say I like it very much. It is far superior to the old *Perilla nankinensis*, which usually turns brown in the autumn, which the new one does not, its colour being a rich purplish black. For large beds or borders when associated with yellow *Calceolarias*, as we have it here, it is fine, and has been much

admired during the past summer. In addition to its capital colour the foliage is deeply cut and serrated, as the latter part of the name implies. I obtained the seed from Messrs. Sutton and Sons of Reading.—GEORGE COOKE, *Nannan Park Gardens, North Wales.*

ROYAL HORTICULTURAL SOCIETY.

SEPTEMBER 17TH.

THIS, the first of the monthly meetings that are held throughout the winter, was not a large one, but was rendered attractive by fine collections of Dahlias from Messrs. Keynes & Co., Mr. C. Turner, and Messrs. Rawlings Brothers. Some good Tuberous Begonias were exhibited, and an interesting collection of fruit was sent by Mr. Rivers; also some good dishes of Tomatoes were staged in competition for the prizes offered by Messrs. Carter and Co. and Messrs. Hooper & Co.

FRUIT COMMITTEE.—Henry Webb, Esq., V.P., in the chair. Mr. Rivers, Sawbridgeworth, sent twenty-two dishes of fruit, amongst which were Stump the World, Radcliffe, Lord Palmerston, and Princess of Wales Peaches. Amongst the Pears was a seedling not named, to which a first-class certificate was awarded on condition that a name be given before the certificate is handed to Mr. Rivers. It is a seedling from Seckle, and of very high quality. Several varieties of Plums were included, mostly seedlings, and promising, especially one raised from Autumn Compôte, which is very prolific, much darker than its parent, and very fine. Gros Maroc Grape was represented by a bunch of fine appearance, the berries being very large and purplish black in colour. A vote of thanks was unanimously awarded for the collection. Mr. Mould sent a seedling Grape, which was not considered equal to other varieties already in cultivation. From Mr. E. Nelson, Dunmore House, Stanwell, and J. C. Atten, Esq., Stamford, came seedling Apples which were of no particular merit. Mr. A. Rann, St. Giles's Cemetery, Cambridge, sent an Apple named St. Giles's Seedling, which was of good keeping quality but not ripe. Mr. D. Abbot, gardener to Charles H. Frith, Esq., Riverdale, Sheffield, sent a seedling Pea, which was desired by the Committee to be tried at Chiswick, also a Tomato, for which a letter of thanks was awarded. From the Society's gardens came Late Admirable, Rivers' White, Exquisite, Belle Imperiale, and Desse Tardive Peaches, also a seedling Peach, No. 40, and Nectarine Albert Victor. Mr. Thomas Andrews, Elmstead Lodge, Bath, sent a seedling Pea, which was recommended should be tried at Chiswick. Some very fine Onions came from Mr. Walker, Thame, showing the same variety raised from winter and spring-sown seed, to which a cultural commendation was awarded. A large and handsome kitchen Apple, D. T. Fish, was sent by Mr. Turner, which measured 13½ inches in circumference. It was gathered from a cordon, and is a variety evidently deserving of cultivation.

For the prizes offered by Messrs. James Carter & Co., High Holborn, for twelve fruit of Vick's Criterion Tomatoes ten dishes were staged, the first prize falling to Mr. R. Phillips, gardener to Capt. Jackson, The Deodars, Meopham, Kent; the second to Mr. C. Ross, gardener to C. Eyre, Esq., Welford Park, Newbury; and the third to Mr. W. Scott, Pembroke Cottage, Cambridge, all showing very smooth and even dishes, but we have seen this variety attain a larger size. Prizes were also offered by Messrs. Hooper & Co. for a similar number of fruits of Acme Tomato. Mr. A. Hopkins was awarded the first prize for very large fruit, and Mr. Miller, gardener to J. Friend, Esq., Northdown, Margate, the second. The Acme is a larger and flatter fruit than the Criterion, but not quite so smooth and firm.

FLORAL COMMITTEE.—Dr. Denny in the chair. Dahlias were the principal feature of the meeting. A very fine collection of sixty named varieties came from Messrs. Keynes & Co., Salisbury, also a dozen promising seedlings, two of which received certificates. Aurora, a beautiful variety of excellent shape; the petals are somewhat pointed, flat, and imbricated; the ground colour is buff with bronzy orange shading; an elegant symmetrical flower, and very distinct. This variety received a first-class certificate. A second-class certificate was awarded to Gaiety, which is also a very large flower, each petal containing three distinct colours, the ground being yellow flaked and striped with red, the points of the petals being tipped with white. A vote of thanks was also awarded to Messrs. Keynes & Co. for the collection. A first-class certificate was awarded to Mr. Turner, Slough, for Dahlia Joseph Ashby, a very bright crimson-scarlet flower, full, and symmetrical. Mr. Rawlings, Romford, also received a first-class certificate for Dahlia Clara, a very striking variety, colour rosy lilac changing to mauve, the centre of the petals being tinted with salmon. To Mr. Cannell, Swanley, were awarded two first-class certificates for single Dahlias lutea and Paragon; the first is clear yellow, about 2 inches in diameter, and very useful for cutting; the other is a beautiful velvety maroon edged with claret, and a most striking flower. Mr. Cannell also exhibited a collection of twenty-four varieties of Pompon Dahlias, a stand of Verbenas admirably set up, the flowers forming perfect pyramids of bloom, the stand being covered with *Lycopodium denticulatum*; also a

stand of French Marigolds, to which a vote of thanks was awarded. Mr. Smith, Edmonton, also received a vote of thanks for a small but good collection of Dahlias.

Begonias.—A first-class certificate was awarded to *Begonia Nellie May*, which was exhibited from Chiswick; plant of robust growth, flowers produced in threes and fours, very large, drooping, and in colour deep rose—a beautiful variety. Messrs. Hooper and Co. sent several dwarf and well-grown plants, including *Louis Thibaut*, a double variety, which received a first-class certificate. The plant is of dwarf habit, with showy orange scarlet flowers suffused with crimson, and is a profuse bloomer. Messrs. Hooper & Co. also received a vote of thanks for their collection. Votes of thanks were awarded to Mr. Noble for *Rose Queen* of Bedders and *Gynierum argenteum pulillum*; also to Mr. Mould for a collection of *Verbenas*.

Messrs. J. Laing & Co., Stanstead Park Nurseries, Forest Hill, were awarded a first-class certificate for *Eulalia japonica zebrina*, a stately Grass-like hardy plant having deep green gracefully arched leaves with pale yellow blotches—very elegant and distinct. Mr. Green, gardener to Sir G. Macleay, Bart., Pendell Court, Bletchingley, exhibited a large flowering head of *Brunsvigia Josephine*, also *Costus speciosus* with large white flowers, *Gloxinia maculata*, the large blue flowers being supported on a spike a foot long. A vote of thanks was awarded. A first-class certificate was further awarded to Mr. Green for *Nelumbium luteum* grown as a fine-foliaged plant. Twenty varieties of *Abutilons* came from Chiswick, and some admirably grown and well-bloomed plants of *Begonia Moonlight*.

Last but not least in importance was a collection of eighteen plants of *Lilium nielgherense*, *Odontoglossum vexillarium* and *Pescatorei*, and some very elegant *Palms* from Mr. Bull; also a fine *Cycad*—*Macrozamia cylindrica*, to which a first-class certificate was awarded. It has bright green, gracefully arching fronds, the base of each leaflet being ivory white. A most elegant and distinct plant. A vote of thanks was unanimously awarded to Mr. Bull for his collection.

NOTES AND GLEANINGS.

MR. ROBERT SMITH, Kenward Gardens, Maidstone, writes to us as follows:—"In perusing the Journal of August 22nd I was much interested with the article on 'AUTUMN PRUNING OF FRUIT TREES,' written by an 'AMATEUR CULTIVATOR, Oron.' I am pleased to endorse your correspondent's opinions regarding autumn pruning of fruit trees. As a practical man I find it is the best means of procuring fruitfulness in Pear trees on walls, likewise as bush or as pyramid Pear trees. I have often found the Pear trees very shy in producing bloom buds with the ordinary method of pruning, but under summer and autumn pruning I find my trees full of fruit buds and looking well. In my opinion you cannot impress the practice referred to too strongly on the minds of the readers of your Journal."

— **EXTRAORDINARY CROP OF POTATOES.**—Mr. Thomas Draycott, gardener to T. T. Paget, Esq., of Humberstone Hall, near Leicester, has this year grown some of Sutton's *Magnum Bonum* Potatoes, and gives us the following particulars of the produce, which he has recently lifted:—"From one hundred roots the produce weighed 6 cwt. 2 qrs. 2 lbs.; one root weighed 13½ lbs., and another 12 lbs. 6 ozs.; one root had forty-eight potatoes to it, and these, when placed in a straight line, measured 15 feet; three potatoes in a straight line measured 26½ inches, one of them measuring no less than 10½ inches. The whole of the crop was sound and of excellent quality."

— We learn from the *Darlington and Richmond Herald* that on Saturday evening last the friends of Mr. RICHARD GRAHAM, late of Pierremont Gardens, presented him with a purse of gold and an illuminated address on his retirement from his profession, in recognition of the services he has for many years rendered to the Horticultural Society, the Darlington Gardeners' Institute, and other societies with which he has been associated.

— ON the 31st of August Mr. William Cosstick, sexton of the Eastbourne Cemetery, had the pleasure of presenting a collection of wild flowers to the Princesses of Hesse, and their Royal Highnesses showed their hearty acceptance of the present by sending a messenger to Mr. Cosstick, requesting him to come to High Cliff House and explain the nature of the flowers, and also to plant the *Drosera* amongst the sphagnum. He also received a special request to collect for H.R.H. the Grand Duchess of Hesse a bouquet of *Erica tetralix* and *Erica cinerea* to take away with her on leaving Eastbourne. He packed it for her, also the *Dosera* for the Royal children, and the wild flowers to take to Germany, with the tickets attached, with English and Latin names, as mementos of the visit to Eastbourne. Their Royal Highnesses were so much pleased

with the *Drosera* that Mr. Cosstick has promised to send a packet of seed to their residence in Germany. The Grand Duchess presented him with a group portrait of the Royal family of Hesse.

— THE REV. C. SMYTHE, Little Houghton, Vicarage, Northampton, sends us the following note on the UPROOTING AND AFTER-GROWTH OF AN ELM TREE:—"In one of the spring gales I had a large Elm tree blown down. The tree lay in its fallen state for a day or two until my men could have time to cross-saw it. Immediately they had done so the trunk flew back into its old position, and has been ever since in full leaf, and has even been putting forth a midsummer growth. The trunk has a few of the lower branches still attached to it, and looks like being none the worse for its fall. Diameter of trunk at the place of cross-sawing 2 feet 8 inches."

— "G. M., *Wemyss Bay*," writes:—"I beg to inform your correspondent (page 191), that Messrs. James Boyd & Sons of Paisley can supply his want in the way of a MACHINE FOR SWEEPING LAWNS AND PATHS. I saw the implement some time ago, and gave it a rough trial in Messrs. Boyd's yard. I considered it as likely to meet a felt want, about this season of the year in particular, when the leaves begin to drop and wormcasts disfigure the face of a well-kept lawn."

— MULBERRIES, writes a correspondent to us, are not so much prized as they deserve to be. In some instances a few are gathered for dessert, and occasionally an individual is met with who is passionately fond of them. They are certainly rather too insipid for the majority of tastes, but if a few are used with Apples for tarts or puddings they impart such a very agreeable flavour as to fairly merit the term "delicious." Where they are plentiful they should be gathered when perfectly dry and made into a jelly prepared in a similar manner to Red Currant jelly, which can be used with light puddings, &c. It is also quite as efficacious for medicinal purposes as Raspberry vinegar, which it in some respects resembles. Large quantities of Mulberries are annually bought-up by wholesale druggists, which are made into syrup and distributed under the name of *Syrupus Mori*.

— SIR SAMUEL BAKER, in a letter to a contemporary, advocates the establishment of a BOTANICAL GARDEN IN CYPRUS, similar to that in Ceylon, under the charge of a competent official, by whom experiments will be made, and the trees most suitable for the climate and varying altitudes of mountain ranges be selected.

ROYAL CALEDONIAN HORTICULTURAL SOCIETY.

THE Royal Caledonian Society held its autumn Show on the 11th inst., when the display of fruit far excelled any bygone show of the Society. The Grapes were magnificent—the theme of general admiration. Probably only on the occasion of the International Show in Edinburgh four years ago has such a large collection of Grapes been brought together in Edinburgh before, and then the quality was not finer, while the Royal Caledonian threw the Carlisle International quite into the shade. Including all the classes the total number of entries was seven hundred, being an increase of three hundred over the highest previous year; and among the list of competitors were more names from the south and the sister isle than formerly, showing that the Society is making its influence felt over an ever-widening radius. The general arrangements of the Show gave general satisfaction, but considering the labour involved in getting together a great Show like this, it seems out of all proportion that the public should only have a few hours on one day wherein to see the Exhibition. Popular interest in horticulture is undoubtedly deepening and widening, and it would be worth the effort if arrangements could be contrived whereby the Show would be extended over two days at least. Just as the toil expended in its get-up is increasing year by year, so the Executive ought to be acknowledged and thanked. Upwards of ten thousand persons visited the Show.

In the competition for the best basket of Grapes Mr. Johnstone, gardener to the Earl of Strathmore, Glamis Castle, was an easy first with splendid fruit. For this competition alone some 3 cwt. of Grapes in baskets were sent in, and in one case 30 lbs. had been cut from one rod. Mr. Kirk of Castle-Douglas, who won the chief prize for a collection of eight bunches, staged Duke of Buccleuch, Black Hamburg, Buckland Sweetwater, and Black Alicante, all exceedingly fine, alike in size, colour, and finish, but the remark might also be applied to almost every bunch on the table. The prize collection of Mr. Johnstone included four varieties of Grapes, a fine Pine Apple, Plums, Peaches, Brown Turkey Figs, Melons, and Nectarines.

In the classes for flowers one of the most worthy was the valuable tables of plants sent in for competition by gardeners. A special prize was offered, and the contest lay between Mr. J. Hammond, gardener to Sir Wilfrid Lawson, Brayton, Carlisle, and

Mr. H. Robertson, gardener to David McGregor, Esq., Lynedoch Place. The Judges gave the place of honour to the latter. Some remarkable Cockscombs were staged, the best, exhibited by Mr. Henry Syme, Ridgepark, Lanark, being $4\frac{1}{2}$ inches from tip to tip by $1\frac{1}{2}$, and of fine quality as well. The stands of Gladioli exhibited by west-country nurserymen were excellent. The first prize went to Mr. David Robertson, Mossend Nursery, Helensburgh; and the second to Messrs. Galloway & Graham, both stands being remarkable for arrangement of spike, massiveness of substance, and well defined yet bright and delicate colour. Dahlias, Fancy and Selfs, were large, finely formed, and coloured. This is a flower for the rearing of which Messrs. Downie & Laird are famous, and their stand of twenty-four was made up of most exquisite blooms. Mr. Hugh Dickson, Belfast, and Mr. Thomas Smith, Stranraer, exhibited Roses. Their stands were pretty equal in merit, and the Roses were good for the time of year. There was keen competition in the class of plants for table decoration, and some excellent Crotons, Dracenas, and Aralias were staged. The first prize fell to Mr. A. McLeod, gardener to R. Smith, Esq., Brencham Park, Stirling. Vegetables were a splendid show.

Nurserymen contributed valuable collections. The Lawson Seed and Nursery Company had a choice group of Conifers, Palms, Todeas, hardy Heaths, &c. Messrs. Dicksons & Co. showed Violas, herbaceous plants, Tree Ferns, Yuccas, and Alpine plants. Messrs. Downie & Laird sent in a profusion of Palms, good specimens of the *Sibthorpia europæa variegata*, Dahlias, Phloxes, and Pansies, and also the *Dionæa muscipula*. Messrs. Thomas Methven and Sons, and Drummond Brothers also contributed good stands of ornamental-foliaged plants. Messrs. Ireland & Thompson had an extra fine collection of the newest varieties of Dracenas, Crotons, and Ferns, including some new seedling Crotons. Mr. Robertson Munro, Abercorn Nurseries, showed a large collection of autumn-flowering Chrysanthemums and Alpine plants. Messrs. Roger McClelland & Co., Newry, exhibited a group of seedling Tuberous Begonias, and were awarded a first-class certificate for one variety, *B. majestica*.—(Abridged from the *Edinburgh Daily Review*.)

CHOICE GARDEN ORCHIDS.—No. 5.

VANDA, Lindl.

Vanda Batemanii, Lindl. (Bot. Reg., 1846, t. 59). Syn., *Fieldia lissochiloides*, Gaudich.; *Angraecum quintum*, Rumph.; *Grammatophyllum panthorinum*, Zipp.—This noble plant deserves a place in every collection, its stately habit rendering it very conspicuous. Leaves 1 to 2 feet in length, sword-shaped, leathery in texture, notched at the oblique obtuse apex, pale green in colour. Raceme erect, 2 to 3 feet long, bearing twelve to twenty flowers, which measure upwards of 2 inches in diameter. Sepals and petals falcate, obtuse, and somewhat wedge-shaped. Colour rich golden yellow profusely spotted with crimson, the reverse side being of a uniform bright purple shaded with violet towards the edges. Lip small, triangular. It blooms at various times during the summer months. Malacca and Philippine Islands, near the seacoast. 1845. (See fig. 36.)

V. gigantea, Lindl. (Bot. Mag., t. 5189). Syn., *Fieldia gigantea*, Rehb.; *Vanda Lindleyana*, Griff.—A majestic plant, worthy a place in every collection, even supposing it never flowered. Leaves broadly strap-shaped, recurved, and deeply emarginate at the obtuse apex, some 18 inches in length, very fleshy in texture, and glaucous green. Raceme pendant, four to twelve-flowered. Flowers thick and wax-like in texture, upwards of 3 inches in diameter. Sepals and petals about equal, oblong ovate, and obtuse, golden yellow, spotted and blotched with cinnamon. Column and lip white, the latter being small. Auricles small, obtuse. Blooms from April to June. Burmah.

V. teres, Lindl. (Bot. Mag., 4114).—Stem ascending, of an indefinite length. Leaves round, smooth, and deep green. Raceme erect, longer than the leaves, three to six-flowered. Flowers large and showy. Sepals bluntly oblong, white, tinged with rosy red. Petals rounder than the sepals, undulate at the edges, and same colour as the sepals, with the addition of a tinge of yellow. Lip large and spreading, somewhat rotund, with an emarginate apex. Side lobes also large, incurved. Colour red and yellow, freckled with crimson. Spur large, funnel-shaped. June to August. In damp hot jungles of Sylhet and Burmah. 1828.

V. teres, Lindl., var. *Andersoniana*, Hort.—This is a very free-flowering form. We do not think it differs much in colour from the normal state of the species.

V. cærulea, Griff. (Warn. Select Orchid. 1st Series, t. 18; Paxt. Fl. Gd. i., t. 36).—This species has hitherto been found somewhat difficult to maintain in good health under cultivation. We believe the reason for this is the fact that it has been the custom to keep it both too hot and dry, growing, as it does, in places where the rainfall is excessive and the temperature by

no means so high as that in which many of the species of this genus revel, such as are found in Burmah, Java, &c. The cultivator should, therefore, bear this remark in mind when passing this species through the ordeal of the East Indian house, and either remove it to the coolest part or place it in the Brazilian or Cattleya house. Leaves channelled, leathery, equally truncate at the ends, with a concave notch and acute lateral lobes, some 4 to 5 inches long and an inch broad. Colour deep green. Raceme erect, 12 to 18 inches high, bearing twelve to twenty flowers, which measure nearly 4 inches in diameter. Sepals and petals large and flat, oblong obtuse, twisted at the base, bearing a short claw. Colour light blue, tessellated with lines of a deeper hue. Lip small, leathery, linear-oblong, obtuse at the point with three diverging lobes, and bearing three parallel perpendicular plates in the disc; side lobes triangular, acuminate. Colour deep violet. Spur short, blunt. It blooms during the autumn months. Sylhet at 2000 to 3000 feet elevation. 1849.

V. Parishii, Rehb. fil.—A somewhat rare and at present little known species, very distinct in habit from any other species yet introduced. Leaves broadly ligulate, unequally bilobed, thick and fleshy in texture, some 6 inches long, nearly $1\frac{1}{2}$ inch broad, and pale green. Raceme erect, bearing several large flowers about the size of those of *V. gigantea*. Sepals and petals cuncate, oblong and slightly undulate. Ground colour yellow, profusely dotted with rich brown, except at the base where they are wholly white. Lip white at the base with two yellow stripes, deep violet in front, and rhomboid. Column white. Summer months. Burmah. 1870.

V. tricolor, Lindl. (Bot. Reg., 1847, t. 59).—A magnificent and well-known species. Leaves linear-lorate, channelled and beautifully recurved, oblique at the apex and deeply lobed. Raceme shorter than the leaves, bearing six to twelve flowers, which are very fragrant. Sepals and petals coriaceous, obovate, obtuse, narrowed at the base, and partially twisted, slightly undulate at the margin; ground colour rich yellow, with numerous reddish brown spots and streaks, the reverse side being white. Lip three-lobed, equal in length to the petals, oblong, or slightly heart-shaped; lateral lobes rounded; middle lobe oblong, emarginate at the apex and deep rose colour, the disc streaked with several raised lines. Spur short, obtuse. April to July. Java, &c. 1847.

V. tricolor, Lindl., var. *insignis*, Hort.—This variety is distinguished by the flowers, which are in the sepal and petals light yellow spotted with crimson. Lip pale lilac. It is a very desirable and free-flowering form. April to July. Java.

V. tricolor, Lindl.; var. *Warnerii*, Hort. (Warner's Select Orchids, 2nd Series, t. 39).—This plant is very rare. It has very strongly ribbed leaves. Sepals and petals similar to those of the variety *insignis*, but having in addition a broad well-defined margin of deep rose. Lip an intense deep rosy purple.

V. tricolor, Lindl.; var. *Rollissonii*, Hort.—In this variety the flowers approach in appearance very nearly those of *V. suavis*; they are, however, slightly different in shape, and are more intensely coloured. It is one of the very best forms. There are numerous varieties of this species, which differ only in the intensity of their colours and markings, the best of which we shall enumerate: *V. tricolor formosa*, *V. tricolor melegris*, *V. tricolor Russelliana*, *V. tricolor Dodgsonii*, and *V. tricolor Leopoldii*.

V. cærulescens, Lindl. (Bot. Mag., t. 5834).—A charming species. Leaves narrow, strap-shaped, 5 to 7 inches long, very leathery in texture, deeply channelled and strongly keeled below; apex truncate, and two-lobed, the lobes ending in stiff sharp points. Colour pale green. Raceme erect, longer than the leaves, many-flowered. Sepals and petals sub-equal, somewhat spatulate, spreading and incurved, light blue. Lip three-lobed, somewhat cuneate and crenulate; side lobes small, dark blue, joined throughout their length to the sides of the column, which is of the same colour; middle lobe rounded; disc deep violet blue, bearing three thick smooth ridges. Spur about the same length as the lip, incurved, acute. March to April. Burmah. 1870.

V. Roxburghii, R. Br.; var. *cærulea*, Hort.—This variety is distinguished only by the colour of the labellum, which instead of being rosy red is a charming cærulean blue. July to August. Assam. 1810.

V. Hookeriana, Rehb.—An extremely rare plant. It has proved, like *V. undulata*, most difficult to establish in our collections. In general appearance it resembles a small and slender form of *V. teres*. Stem ascending. Leaves terete,

Fig. 36.—*VANDA BATEMANII*.

slender and bright green. The sepals and petals are about equal in size, and, together with the lip, are white tipped with rosy lilac. It has not yet flowered in this country. Upper Assam. 1860.

NORTHAMPTON HORTICULTURAL SHOW.

ALTHOUGH many good and successful horticultural shows have been held at Northampton, the Northampton Horticultural Society is yet in its infancy, and the second annual Exhibition was held on Thursday and Friday last on the racecourse, in connection with the Show of the Northamptonshire Agricultural Society, which has, through the energy of its courteous and able Secretary, Mr. J. M. Lovell, developed into one of the most important of local societies. It almost seems a pity that the county, with so many rich and zealous devotees and patrons of horticulture, should not also possess a county horticultural society, for it has been the custom of the Agricultural Society, as it itinerates annually from town to town in the county, to ally itself with a local horticultural society or show.

Studded as Northamptonshire is with the seats and gardens of noble owners, and possessing a goodly array of botanists and of gardeners of all classes, few counties are better placed for a county horticultural society. Furthermore, it possesses some good garden land, of which, if other evidences were wanting, one has only to pass on a market day through the rows of excellent fruit and vegetables which are to be seen in the noble market-place of which Northampton boasts as one of the finest in the kingdom, to ascertain that all the best vegetables do not come to Covent Garden. Northampton, however, like several other towns in the county, has done its best to supply the want of a county horticultural Society, and the Show I visited on Friday last did not discredit its agricultural neighbour.

The leather metropolis favoured with glorious weather was not only profusely but prettily and appropriately decorated, and the throngs who flocked to the town and to both Shows tell how much the neighbourhood appreciates both good horses and good flowers. The competitive part of the horticultural Show was comprised in five marquees, the local nurserymen, Messrs. John Perkins & Son, Messrs. Thomas Perkins & Son, and Messrs. Ball and Co., each having also a large marquee well stocked with their own productions; but more canvas was necessary: further, the magnificent plants belonging to Messrs. Cypher, House, Parker, and others were totally unprotected, the passages left being far too narrow to prevent injury to the specimens. The difficulty, I am aware, generally arises from the entry system not being sufficiently stringent, many exhibitors at the last moment omitting to fulfil their entries for reasons which do not always come to light; and if the Newcastle system of fines for non-compliance works well it might be worth extending to more southern shows. It is not always easy to hit the exact medium, but generally an allowance of one-fourth or one-third (the latter in adverse weather) will meet the circumstances, and it should always be taken into consideration. At Nottingham two years ago all the entries were liberally provided for, and consequently a large and otherwise good Show was spoiled in effect by the predominance of blank boards.

At Northampton, as a consequence of the limited space at the command of the Committee in proportion to the extent of the Show, the arrangements were somewhat defective, cut flowers and vegetables being in several different tents, and some of the latter (not the worst) under the tables. A much better plan, especially where the judging has to be classified and divided for different judges, is to keep each department as nearly as may be separate, allowing cottages, however, a tent for themselves, as the latter are often inconveniently zealous to see other exhibits at the time of staging.

In the open class Mr. J. Cypher of Cheltenham had evidently not left his finest plants at home, and was placed first for a collection of twelve stove and greenhouse plants in flower, Mr. Parker of Rugby and Mr. House of Peterborough being respectively second and third with somewhat smaller but healthy and well-grown specimens. For Ferns in the open class Mr. Cypher was first for six, and Mr. J. Holland, gardener to John Phipps, Esq., Northampton, second. For eight foliage plants in the same class Mr. House was first; Mr. Farr, gardener to Sir R. Knightly, Bart., Fawsley Park, second; and Mr. Parker third. In the gentlemen's gardeners' class Mr. H. Ward, gardener to W. Jeffery, Esq., Northampton, was first for six stove and greenhouse plants; and Mr. J. Day, gardener to A. Seymour, Esq., Norton Hall, Daventry, second. Amongst cut flowers the Rose claims my sympathies, and therefore I give it first place, and in order that I might have a test of the persistency of autumn Roses I deferred my visit to the Show until the second day; if, then, my opinions differ from those of others who saw them on the first day allowance must be made accordingly. Some good blooms were staged, especially in the open class for twenty-four singles, in which Mr. J. Sladden of Chipping Norton was first, the cream of his lot being Madame Sophie Fropot (unequaled as an autumn-flowering light Rose), Henri Ledechaux, Marquise de Castellane, Catherine Mermet

Marguerite D'Ombraïn, and Comtesse d'Oxford. Madame Prosper Langier was, however, ragged and flat, and when yellow eyes become the rage Duchesse d'Ossuna may be considered a beauty. In this and other stands from Mr. Sladden the colours were conspicuously bright, and there must either be something in the Oxfordshire soil, or it may be the seedling Briar that causes this. Certain, however, it is that brighter Roses come from Oxfordshire in the autumn than from most other localities. My own opinion is that lime has something to do with brilliancy of colour. Mr. G. Howes of Daventry was second for the twenty-four, having good blooms of Marie Baumann, John Keynes (which is remarkably fine this autumn), and Exposition de Brie. Mr. Wm. Jackson, Blakedown Nurseries, Kidderminster, was third with blooms evidently cut some hours before those in the other stands, and here Leopold I., Victor Verdier, M. Boncenne, and Antoine Mouton stood well. For twelve varieties, singles, in the open class, Mr. Sladden was again first, having Madame Sophie Fropot and Souvenir d'Elise, very fine. Mr. Howes was second. In the gentlemen's and gardeners' class the Rev. W. H. Benn, Church-over Rectory, Rugby, was first with Marquise de Castellane, Alfred Colomb, Maréchal Niel, Anna Ollivier, Cheshunt Hybrid, Madame C. Wood, Jules Margottin, Capitaine Christy, Gloire de Dijon, Pierre Notting, Baronne de Rothschild, and Sénateur Vaisse. Mr. H. Ridge of Whittlebury was second. Mr. Sladden had also an excellent stand, and which in the advanced stage seemed to distance those of his competitors. He had Marie Van Houtte (excellent), Dupuy-Jamin, Madame Sophie Fropot (A1), Charles Lefebvre, John Hopper, Maréchal Niel, Capitaine Lamure, Devoniensis, Madame H. Jamin, Belle Lyonnaise, Madame Victor Verdier, and Lord Macaulay; all good. In a class for twelve blooms, open to amateurs and gardeners, the Rev. W. H. Benn was again first, having good blooms of Duke of Edinburgh and Pierre Notting. In the amateurs' class a good six came from Mr. H. Ridge of Whittlebury, who was first, Mr. A. Coates of Wellingborough being second. *Gladulus* in the open class were fairly well shown by Mr. Sladden, who had *Lacépède*, *Cerimene*, *Mathilde de Landevoisin*, *Eugène Scribe*, *Le Vesuve*, *Le Phare*, *Marie Dumortier*, *Carnation*, *Addison*, *Fulton*, and *Tintoret*, purplish rose, flaked carmine, large, and good shape. Messrs. Thomas Perkins & Son, Northampton, were second, having *Jupiter* (good), *Marie Stuart*, *Mons. Desportes*, *Reine Blanche*, pure white, with throat slightly marked carmine, but not good shape; and *Leander*, striking in colour, the flowers having an Iris-like appearance.

Dahlias were very good, especially those in the open class from Mr. Jackson of Kidderminster, who was *facile princeps* both for the twenty-four and twelve Show varieties; Messrs. Thomas Perkins & Son were second, Mr. Jackson being again first for twelve Fancy varieties with a fine stand. For twelve Show varieties in the gentlemen's and gardeners' class Mr. H. Ridge of Whittlebury was first with good blooms, and Mr. E. C. Adams, Lower Heyford, second. *Asters* were not good, with the exception of Mr. J. Betteridge's stand of his large quilled strain, which now approach in size the incurved and tasselled varieties. Plants of *Zonal Pelargoniums* showed an excess of foliage and a paucity of flowers, the best coming from Messrs. J. Perkins & Son, who were also first in the open class for double *Zonals*; and Mr. Farebrother, gardener to R. Turner, Esq., Northampton, in the gardeners' class second. If "*White Wonderful*" is put forth as a sport from its attractive and floriferous namesake the plant I saw here does not confirm this origin, its habit, foliage, and flower being quite distinct, and certainly there are far better double whites, notably Madame A. Baltet and Mrs. Trevor Clarke. Prizes were offered for wild flowers, but rare types were wanting, many of the specimens shown being unclassified and incorrectly named.

For dinner-table decorations Mr. Cypher's tasteful hand and eye coupled with his rich floral stores brought him to the fore with a very elegantly dressed table, his decorations being neither sparing nor profuse, and glaring colours not being too dominant. Mr. Haskins of Stone Gardens, Buckingham, was second, and Mr. Parker third. The best bouquets both for table and hand came from Mr. Cypher, and the prize for one made by a lady of the county fell to Miss Beran of Brixworth. Model gardens are generally a feature at Northampton, and always prove attractive to the masses, and on this occasion the labours of the exhibitors were not thrown away. The prize models shown by Mr. Porter James of Northampton, and by Mr. James Toogood, gardener to the Hon. C. W. Fitzwilliam, who were first and second, displayed not only much industry but more taste than is usual with these toys.

Fruit was good and largely shown, but the staging of the collections on plates spoiled the effect. In the open class Mr. Chater, gardener to Sir Charles Isham, Bart., Lamport Hall, was first; and Mr. J. Day, gardener to A. Seymour, Esq., second for a collection of eight varieties; and in the gentlemen's and gardeners' class Mr. Day was first for six varieties, and Mr. Farr second. The latter had Colston Basset Melon, a tempting-looking small variety. Very good Black Hamburg Grapes came from Mr. Wm. Miller, gardener to R. Soder, Esq., Whittlebury; and White Muscats from Mr. Day, who were each first in the open and

gardeners' classes. Two fine bunches of Dr. Hogg proved that this variety is worthy of its name, the colour being a very rich amber, and the bunches large. In Melons Sutton's Hero of Bath and Gilbert's A. F. Barron were the best. Peaches and Nectarines were scarcely up to the average, but Apples, Pears, and Plums were well and largely represented. Amongst Apples Lord Nelson, Bedfordshire Foundling, and Northern Spy were conspicuous for size; Lord Suffield, and a small streaked Pippin named Lord Lennox, seem to be two of the most popular varieties in this locality; Williams' Bon Chrétien in Pears and Coe's Golden Drop in Plums occupying a similar position. But the finest dish of Pears was one of Souvenir du Congrès from Mr. Marshall of Whittlebury, to which the first prize in the amateurs' class was awarded; this is evidently one of the best Pears of modern introduction.

Vegetables, especially Potatoes and Onions, were very good and clean. For the collection of six varieties Mr. Day was first, and Mr. T. Eads, gardener to J. Beck, Esq., Northampton, second. For a collection of twelve varieties of Potatoes in the open class Mr. W. Emerton, Cold Ashby, Rugby, was first, having Heather Bell (a fine purple-splashed kidney), Lye's Favourite, Robertson's New White (a roundish flat sort), Schoolmaster (large, clean, and good), Snowflake, Countess, Trophy, Red Emperor, Purple Fluke, Farquhar's Favourite, and Beauty of Hebron (good). Messrs. Ball & Co. were second. The best Potatoes, however, in the Show and one of the cleanest and most select lots I have seen anywhere, came from Mr. Eads, who showed for six varieties in the gardeners' class Fenn's International and Model, two veritable models; Schoolmaster, Sutton's Magnum Bonum, Snowflake, and Porter's Excelsior, all likewise nearly perfect, and, perhaps, these six varieties constitute the *crème de la crème* of exhibition varieties, as in so small a selection coloured sorts are hardly admissible. Mr. Emerton was second with larger and very fine specimens, but his lot had evidently seen the "light of other days" before coming to Northampton. Mr. Emerton staged two collections, and amongst them were Trophy, Henderson's Prolific (a roundish-flat variety of the Handsworth type), Grampian, Lady Webster, Excelsior, and Blanchard. For single dishes in the amateurs' class Mr. A. Coates was first for kidneys with Snowflake, and for rounds Mr. George Wilcox with Red-skin Flourball. The best Onions were White Spanish, shown by George Turner, Esq., Mr. Eads, and Mr. Russell, gardener, Boughton House. Mr. Turner's were the largest (15 inches in circumference), but those shown by Mr. Eads of the yellowish-skinned variety were very clean and sound. Cucumbers and Peas appeared generally past, but Intermediate Carrots were good. In the cottagers' class remarkably good vegetables were shown.

The Show was altogether a successful and an attractive one, and the perseverance and tact of the Committee and the Hon. Sec. (Mr. Cordeux), have well sustained the reputation of the Northampton Shows. A good and thoughtful feature was the admission on the second day at four o'clock of school children at 1d. each, a privilege which seemed to be well appreciated.—T. LAXTON, Bedford.

EXHIBITING CARNATIONS AND PICOTEEES.

"TIME bringeth its revenge," and it has done so to me in this matter. Some two or three years ago I deprecated the barbarous system of showing these flowers, and said I hoped the day was coming when it would no longer be practised. Had I committed the seven mortal sins I could not have been more bitterly assailed. I have no wish to recall these things, and I do it in no irritation. I knew I was right; and although my notions were considered crude, the result of incapacity and ignorance, and I was not even deemed worthy of the name of florist and had never done anything to benefit floriculture, yet somehow or other I believed I was taking a course which would commend itself to common sense, and if it did so would win its way. As far as I recollect I said—1st, That there was no flower exposed to the same treatment with the exception of the Pink, so nearly allied to it; 2nd, That it was misleading to the general public, who know nothing of the mysteries of dressing; 3rd, That however skilful the cultivation might be, success was really with the most skilful dresser; 4th, That it was absurd to make a rule that no mutilated flower was to be exhibited when any number of petals might be taken out, mutilation meaning in this connection not taking from but adding to; 5th, That it was strange that to cut out the eye of a Dahlia should disqualify, while the exhibiting of even half the petals of a Picotee was allowable.

This year the second annual exhibition of the southern section of the National Carnation and Picotee Society was held at South Kensington, and I subjoin a few, and a few only, of the comments made upon it. One of your contemporaries says, after alluding to the success of the show regarded from the point of view of the professed florist, "At the risk of being

considered rash heretics we venture to dispute the assumed excellence of the present mode of exhibiting these flowers. Is it necessary, for instance, that the flowers, no matter what their colour may be, should be throttled by a stiff collar of dead white cardboard projecting all round the flower for some distance?"

Another says, "It is high time to protest against the way in which these lovely flowers are made hideous at shows. A bed of seedlings left alone has a better effect than all the collared Carnations ever seen. We do not wish to quarrel with the florist for his ideal, and let him lay down all the rules and standards of perfection which he likes. What we have to deplore is the fact, that after ages of effort and not a little vaunting of what has been done, the ideal flower is only to be seen in a deep paper collar, with all its delicate beauty of varied petal destroyed, flattened, or pushed out. Each exhibitor is armed with a small series of instruments, reminding one of a dentist's collection, wherewith the said exhibitor extracts small petals, flattens others, and goes through a variety of operations to force the flower to assume for an hour or two before its death a shape which he calls perfect. All this might be tolerated if at the same time these beautiful flowers could be seen as they grow. This is all we ask for. A show of Carnations and Picotees well grown in pots, and allowed to bloom without mutilation or objectionable collars, would be a charming novelty, and we should see in what way the flowers look best. We believe the usual way of showing them is that calculated to exhibit to the least possible advantage the beauty and grace which Carnations and Picotees naturally possess."

A third gardening paper says, "As usual at these shows each flower had a paper collar affixed round its neck. Exhibitors say this is not to keep the flowers from splitting or the petals from falling, but to show them off to the best advantage. If this is so why are these flowers shown in stands provided with collars? Would not a sheet of paper placed over the boxes answer as well? This practice, as well as that of mutilating the flowers with pincers and other instruments, are a disgrace to lovers of flowers, and are a means of deceiving the public who are ignorant of such maltreatment; and it is no more right for exhibitors to take from or add to their flowers than it is for exhibitors of animals to cut off their ears or tails."

The *Journal of Horticulture*, our Journal, through one of its most welcome contributors gave the same last week, and my excellent friend "WYLD SAVAGE" writes so trenchantly that I must add a few of his words to this array of authorities. "I have never seen florists dressing their flowers before, and I must express my opinion that it was a very unedifying sight. The lovely flower was seized by the scruff of its tender throat, much like a poor victim is seized by the dentist, and a pair of ivory tweezers were employed in pulling every single petal out of its place. 'I say, old fellow, have you seen these Carnation fellows dressing their flowers?' said a brother rosarian to me. 'They are like a lot of ladies' maids' I answered, 'preparing their mistresses' heads for a ball.' If this practice goes on we shall come to this: It will not be the best florists or the best flowers that will win; it will be the most skilful operators and the most highly dressed and artificial flowers that will carry off the prizes."

Now I know it will be said, "These are all outsiders: they do not look at it from the florist's point of view, and hence their opinion is worthless." But I am convinced of this, that when outsiders have common sense on their side they must ultimately prevail. But I have the last shot in my gun as the best. I read in the account of the northern show of Carnations and Picotees that the premier prize for the best Carnation was awarded to Mr. Rudd for a bloom of Mercury as cut from the plant. When I saw this, remembering that the north is the very Mecca of the florist, I could not help exclaiming, Hurrah!

I thus see in these extracts all that I contended for advanced, and I cannot but hope that something may arise from this unanimous chorus of disapproval. If the Committee would offer prizes for uncut flowers—*i.e.*, flowers from which no petals are extracted, I am quite sure it would be accepted as a boon by the public, and unquestionably those who now exhibit these marvellous specimens of dressed flowers would be equally able to show well the raw material out of which they are manipulated. The arranging of the petals in order I should no more consider wrong than the arranging the bells of a Hyacinth or the truss of an Auricula, but it is this mutilation, this metamorphosis of the flower, which is to me so contrary to all ideas of fair treatment.—D., Deal.

P.S.—By the way, if one man grows Carnations and Picotees

and is ignorant how to act as their man milliner, and he cannot under the present system of showing hope to obtain a prize, and obtains therefore the aid of a good dresser to do them for him and he wins, to whom ought the prize to go?

BRIGHTON AUTUMN SHOW.

ON the 11th and 12th inst. the Brighton and Sussex Horticultural Society held its autumn Exhibition of fruit and flowers at the Pavilion. The display was a fine and extensive one, filling a large tent on the lawn and the suite of five large rooms opening into each other and extending along the entire front of the ground floor of the building. The public attended in such large numbers as to render our work of notetaking somewhat arduous, many of the tables being so beset that it was only by following along with the streaming crowd a sight of their contents was to be had, and so it becomes our pleasant duty to record the success of a Show that was quite worthy of it. True it is that the plants in some classes were inferior to the recognised standard of excellence, and that among cut flowers the Roses, owing to the inclement weather that has lately prevailed, were much below par, yet in other classes we found ample compensation.

PLANTS.—Of these there was a goodly array, as was to be expected from the liberal offer of three prizes each in twenty-six classes. The magnificent group of eight ornamental-foliaged plants by Mr. W. Balchin, nurseryman, Brighton, to which a first prize was awarded worthily, attracted much attention. Nearly all of the plants were models of skilful culture, *Areca sapida*, *Pheniceophorum seychellarum*, *Cycas revoluta*, *Encephalartos villosus*, and *Croton majesticum* being specially good. This plant last named, besides being of great size and fine form, possessed the high merit of being the only really well-coloured *Croton* in the Show. Mr. W. Miles came second, and Mr. Meachin third in this class. In the class for four plants of similar character Mr. Meachin, gardener to Mrs. Armstrong, Woodsee, Preston, came first with a fine *Yucca aloifolia variegata*, a large *Pandanus Veitchii*, and a couple of *Crotons*. For eight stove and greenhouse plants Mr. Balchin was first with a large well-furnished *Rondeletia speciosa* major with plenty of flower buds but not many open flowers, a *Dipladenia splendens* tolerably well flowered, a large plant in fine bloom of the familiar *Bougainvillea glabra*, and the equally familiar *Ixora javanica floribunda*, the rich yellow *Allamanda Cheloni*, and others. Mr. Meachin was a close second, his plants, although smaller, being remarkable for their finish and freshness, the best being *Erica retorta* major in fine bloom, a capital *Rondeletia*, a *Stephanotis*, a *Vinca*, and *Allamanda Hendersoni*. The prizes in the smaller class of four stove and greenhouse plants were awarded—first, Mr. J. Child, gardener to Mrs. Torr, Ewell; second, Mr. W. Miles, West Brighton Nursery; third, Mr. W. Huggett, gardener to Dr. Jeffery, Eastbourne. A few good plants were brought into competition for the prizes for single specimens, Mr. W. Balchin being first with a grand example of *Allamanda Hendersoni*, with such an abundance of flowers that we could not but regret they were not distributed equally about the plant instead of being brought together in a crowd to form a "face." Mr. Meachin came second with so good an example of *Vinca rosea* that the Judges must have experienced some difficulty in coming to a decision. The plant was one mass of bloom and some 4 to 5 feet in diameter. In another class for single specimens Mr. Howick, gardener to A. Granville Utterware, Esq., was first and Mr. Meachin second. The six *Coleuses* with which Mr. Howick easily gained a first prize formed one of the most striking features in the tent. They were trained to the form of low cones, very broad at the base, tapering upwards with singular precision and were very bright in colour. Mr. Balchin's first-prize group of eight exotic Ferns consisted of *Davallia Mooreana*, very fine; a good *Dicksonia antarctica*; *Adiantum concinnum latum*, a mass of elegant dark green fronds; *Davallia pyxidata*, 6 to 8 feet in diameter; *Cibotium regale*, looking well worthy of its name; *Davallia elegans*, 3 to 4 feet high; and fine plants of *Dicksonia squarrosa* and *Alsophila australis*. In the group with which Mr. Child took second honours there were an excellent *Leptopteris superba* with fine dark green, pendant, fringed frondage, and a *Gleichenia Mendelii* in good health, 5 to 6 feet in diameter.

The response to the offer of a cup value £10 for ten Orchids by the Brighton Railway Company was unsatisfactory, only two lots of small plants being staged. Of these, the ten shown by Mr. Rutland, gardener to the Duke of Richmond, gained the cup, Mr. Meachin coming second with a group very little inferior to the others. *Begonias* in flower were much better than at the summer show, Mr. E. Cosham, gardener to R. Insoll, Esq., Eastbourne, being first with four large and very handsome plants. *Fuchsias* were also very good—much better than we have ever seen them at Brighton, and were shown in considerable numbers, Mr. W. Penfold taking first honours, Mr. Shrivs second, and Mr. Meachin third. Zonal *Geraniums* were excellent and numerous; gold and silver tricolors were also represented fairly well. Here Mr. Meachin shone pre-eminent, taking all four first prizes. Useful groups of mixed plants were contributed by Mr. Spary, Mr.

Miles, and Mr. Balchin, the three Brighton nurserymen, which were much admired by the visitors, who further gained many useful hints from the courteous attendants about novelties for conservatory decoration.

TABLE DECORATIONS.—These were confined to sets of three stands. Mrs. W. Seale, London Road, Sevenoaks, taking first prize; Mr. R. Downing, gardener to A. Allison, Esq., Crawley, second; and Mr. F. W. Seale third. The whole of the stands were meritorious, lightness, elegance, and refinement being prominent characteristics in every one of them. This feature of the Show was a popular one, and we heard repeated expressions of delight from the throngs pressing along the sides of the tables.

CUT FLOWERS.—*Asters*, *Dahlias*, *Zinnias*, and *Verbenas* were all well represented. *Gladioluses* were not so plentiful, only two collections being staged; Mr. S. Dobree, Wellington, Somerset, taking the first prize, and Mr. Balchin second. The stands of twenty-four varieties of cut flowers were very beautiful, Mr. Rutland and Mr. Balchin both taking first prizes.

FRUIT.—The display of fruit was a noble one, the Grapes being especially remarkable for size and finish. Black Grapes were well coloured almost without exception, and the bunches so good that the contest for prizes was a severe one. For three bunches of Black Grapes Mr. J. Spottiswood, gardener to C. Duddell, Esq., Queen's Park, was first in two classes, his Black Alicante being excellent; Mr. G. Osborne being first in the class for six bunches of Black Hamburg. Mr. C. Tyler of Bishop Stortford gained a first prize with his Muscat of Alexandrias, as also did Mr. G. Osborne. Melons were both numerous and fine, there being upwards of thirty fruit, Mr. J. Budd, Mr. S. Ford, and Mr. Holford taking prizes in the open class in the order in which they are named, and Mr. Atrill, Mr. Wickham, and Mr. Wilkinson doing the same in the county class. Some good collections of fruit were shown, Mr. Rutland taking the first prize. Peaches, Nectarines, Plums, and Pears were all shown in considerable quantities, and the exhibition of Apples was especially good, the dishes, especially of kitchen Apples, being very numerous and the fruit fine.

Our report would be incomplete without reference to the wax flowers for which Brighton is so famous. An extensive collection of such flowers as Roses, baskets of blue and white Violets, Primroses, and Lily of the Valley, sprays of Passion Flower, Apple blossom, Orange blossom with foliage, Azaleas, Camellias, Heliotropes, dinner-table stands, hand bouquets, and plants in pots, all done so skilfully and so closely resembling Nature as to merit general appreciation.

HYDE PARK.

WHATEVER may be said in praise of either Battersea or Victoria Parks they certainly do not eclipse Hyde Park, although at a first glance, being more compact, the effect may be more striking. In Hyde Park are to be found long avenues of shady trees, consisting principally of Elms and Planes; delightful banks sloping down to the Serpentine, and many pleasant walks, rides, and drives, altogether offering such facilities for enjoyment as most country towns and villages might well envy.

A great feature, and what adds so much to the attractions of this and other parks, is the summer bedding. This is always carried out extensively and well, thus giving pleasure to thousands of visitors, and also helping to promote and improve this branch of gardening throughout the country. The present season has been rather unfavourable to bedding plants generally, but at the same time we find that Nature compensates here as elsewhere, for where we usually saw parched and sun-burnt banks we now find the grass and vegetation generally remarkably fresh and green.

Early in the season the Pelargoniums and other kindred bedding plants looked wonderfully bright and well, but they now look sadly alongside of their brighter if lowlier neighbours in the carpet beds. The latter are scarcely so neat as they were a few days back: this is the consequence of taking all the men to do other really more important work—viz., the remaking of paths and roads and renewing the turf wherever necessary, of which there is much to do every season. Others would do well to take Mr. Chamberlain's advice in this respect, he rightly considering this the best time for the work. Grass seed sown now will form excellent turf well able to withstand drought the following season, which is seldom the case with spring-sown lawns, at all events where the soil is as shallow as in Hyde Park.

The flower beds between the Marble Arch and Stanhope Gate consist of a series of plain beds in lines, around which are to be found the principal carpet beds and the ordinary bedding plants. As before stated, the carpet beds look much the brightest, and are certainly well done. Some of the beds

are perfectly flat; others, however, are a step in the right direction, being dotted with many varieties of succulents and other plants, which help to relieve the extreme flatness considered so unnatural and objectionable by some. The brightest coloured plant used is the *Alternanthera amena*; the prettiest and best green, the *Mentha Pulegium gibraltaria*. The Golden Feather is still indispensable and is used in large quantities. The old-fashioned bronze *Oxalis corniculata rubra* is also used and looks extremely pretty. Some of the designs are quite original and well worthy of imitation.

Pelargonium Bonfire is the only variety found with any quantity of bloom, most of the others looking very weather-beaten and appear to have suffered more than those in many private country gardens. Mixed beds still look attractive, notably two filled with a mixture of silver variegated *Pelargonium Miss Kingsbury* and *Iresine Lindenii*, surrounded with *Golden Pyrethrum* and edged with a blue *Lobelia*; and another pair filled with a mixture of silver variegated *Pelargonium Ariosto*, and edged with *Alternanthera paronychioides major* margined with *Echeverias*.

It is, however, between the Wellington and Albert Gates, or south-east side of the Park, where the most generally interesting beds are to be seen. These are also plain beds, and are irregularly placed on both sides of the drive and intermingled with the large deciduous and other trees. Some are on, others above the level, and others again springing out of the banks. Raised beds are frequently found fault with, but for showing off subtropical plants they are unequalled, and being better drained are certainly more conducive to success. Many of the largest beds are filled with subtropical plants, and there are many specimen Palms dotted and grouped among them. Very noticeable are two fine specimens of *Scaevola Cunninghamii*. Of other specimen Palms used are good examples of *Chamærops Fortunei*, *Phoenix farinifera*, *P. reclinata*, *Latania borbonica*, &c. Two beds of succulents arrest attention, in which plants of *Yucca aloifolia variegata* appear to the best advantage. A bed of *Musa ensate* also looks grand, as do the *Cannas* and *Solanums*, although I did not observe anything new among them. One large bed filled with *Erythrina crista-galli*, with a few plants of variegated Maize intermingled and edged with ordinary bedding plants, was earlier in the season very attractive. Among the general bedding plants I noticed *Coleus refulgens* as being a capital substitute for the *Perilla*. It is nearly as compact as *Coleus Verschaffeltii*, and the colour the counterpart of the *Perilla*. *Tricolor Pelargonium George Sandy* looked very bright, but is scarcely so vigorous as one would wish. This, however, is a recommendation if used as at Hyde Park—i.e., dotted among *Lobelias*.

A short distance from and nearly opposite to the Albert Gate is to be found a delightful nook or dell, which is undoubtedly one of the prettiest spots in the Park. It is nearly triangular in shape, and is surrounded on two sides by banks of evergreen shrubs and deciduous trees. The enclosure gradually slopes to the ends in an irregular line down to a watercourse. Springing out of this on both sides at intervals are Ivy-covered banks, on which are grouped plants of *Aralia Sieboldii*, *Phormium tenax variegatum*, *Monstera deliciosa*, &c.; and following the water in the distance are to be seen large specimens of *Cordylines indivisa* and *australis* springing from among the banks of evergreens. In the centre of the enclosure is plunged a magnificent specimen of *Latania borbonica* fully 15 feet in diameter; and about this are artistically grouped but not crowded, the pots or tubs being plunged in the turf, numbers of fine tall specimens of *Cordylines nutans*, *australis*, and *lineata*; *Scaevola elegans*, *Latania borbonica*, *Musa ensate*, *Chamærops excelsa*, *Pandanus ornatus*, &c. On the banks sloping towards the drive, running past the Albert and Wellington Gates, are placed several very fine beds filled with subtropical foliage plants. The largest, a circular bed 36 feet in diameter, is undoubtedly the grandest bed in the Park. In the centre is a very fine *Musa ensate*, and around this are arranged other *Musas*, *Ricinus*, *Solanums*, *Eucalyptus*, *Pol-hymnia grandis*, variegated Maize, &c., surrounded with a band of *Perilla nankinensis* and fringed with *Funkias*: all look healthy and very vigorous. Near this is a bed filled with Palms. Large beds of *Cannas* also look well.

Many large clumps of deciduous and evergreen flowering trees and shrubs with a margin of herbaceous plants help to make the Park attractive. Altogether there is much in the Park worthy of imitation by gardeners, and no doubt there is something to avoid; but I am reminded that it is easier to find fault than to suggest remedies, to criticise than to instruct. Mr.

Gibson and his coadjutor Mr. Chamberlain deserve a hearty vote of thanks for the excellence of their work; let it be given ungrudgingly by the many who have derived pleasure and instruction from the exercise of their taste and skill.—W. J. O.

BRENTWOOD HORTICULTURAL SOCIETY.

AUTUMN SHOW, SEPTEMBER 12TH.

Do not committees frequently err by holding flower shows early in the season? If (when only one show can be provided for) instead of June and July they selected the end of August or early in September, a much more varied and interesting show of fruit, vegetables, and florist flowers would be obtained, and nearly, if not quite, as good a display of plants; the only real loss would be hardwooded plants, but the gain in other classes would be abundant compensation. Fruit, especially when well and largely shown as at Brentwood, cannot fail being admired; it is also instructive to a number of competitors and visitors.

At the Show under notice plants were of secondary importance, and but few prizes were offered for them. For a miscellaneous collection Mr. Bones, gardener to D. McIntosh, Esq., was first, and Mr. Bradley, gardener to O. E. Coope, Esq., M.P., was second, both showing excellent groups. Mr. Mann, nurseryman, Brentwood, had some excellent *Fuchsias*, and received the first prizes in both classes for them. The baskets of plants in pots were very good indeed, and other societies would do well to provide a similar class. Messrs. Saltmarsh & Son, Chelmsford, were first, and Mr. Ford, Warley, second. *Pelargoniums* were also well shown, Mr. Mann having the best.

Cut flowers were exhibited in great numbers, the Dahlias and Asters being very fine. In the class for twenty-four Dahlias Messrs. Rawlings Bros., Romford, were first with a very fine and even lot, the names of which, for the benefit of exhibitors, we append:—John Bennett, James Willing, John Standish, James Service, J. H. Keynes, James Cocker, Rev. J. B. M. Camm, Clara, Rev. J. Goodday, O. E. Coope, Countess Tasker, Flora Wyatt, Mrs. Harris, Alexander Cramond, Julia Davis, Monarch, Christopher Ridley, T. Goodwin, Countess of Pembroke, Mrs. J. Downie, Willie Eckford, Henry Walton, Mrs. Shirley Hibberd, and J. W. Lord. Messrs. Saltmarsh were second. In the amateurs' class for twelve Mr. J. Hill, Warley, had an excellent stand and was first, and there were also several other good stands both in this and the class for six, where Mr. C. Lavender, Sherfield, was first. For twelve Roses Mr. Atkinson, Brentwood, was first with excellent blooms of *Souvenir de la Malmaison*, *Marie Baumann*, *Madame Victor Verdier*, *Dupuy Jamin*, *Alfred Colomb*, *Sénateur Vaisse*, *Baronne de Rothschild*, *Countess of Oxford*, *Charles Lefebvre*, *Duke of Edinburgh*, *Maréchal Niel*, and *Etienne Levet*, all alike of good size and colour, and superior to stands which sometimes gain the premier awards at local summer shows. Many of the varieties named were in the other stands and classes, and we noticed some excellent blooms of *Marquise de Castellane*, *Beauty of Waltham*, *La France*, *John Hopper*, *Captaine Christy*, *Edouard Morren*, and *Madame Pauline Lafontaine*.

The vases for table decoration were very tastefully filled, but were much too tall, several of them being fully a yard or more in height. Messrs. Burley, Bailey, and Soder were successful in these classes.

For a collection of six varieties of fruit Mr. Bones was a creditable first, and Mr. Pope, gardener to W. R. Preston, Esq., Harold Wold, a good second. None of the Grapes in the various classes, with the exception of *Lady Downe's*, shown by Mr. Carver, gardener to C. Postans, Esq., Brentwood, and Mr. Worthing, gardener to A. Moss, Esq., Chadwell Heath, were particularly good, in some instances being too ripe, in others—the *Muscats* more especially—being scarcely ripe enough. Messrs. Ford, Carver, and Bones were all winners of first prizes in the classes for Grapes. Mr. S. Ford was first for a green-fleshed Melon with an unnamed fruit resembling *Eastnor Castle*, and Mr. Bones for a scarlet-flesh with a small fruit of *Hero of Bath*. The first prizes for both indoor and outdoor Peaches were awarded to very fine fruit of *Late Admirable*, the former being staged by Mr. Clark, Brentwood, and the latter by Mr. S. Ford; and the chief prize for *Nectarines* grown on the open wall was awarded to Mr. Parker, gardener to the Countess Tasker, for a fine dish of *Murrey Nectarine*. Pears were shown in great quantities, but in many instances *Williams' Bon Chrétien* was too ripe, the first prize for a dish fit for the table being awarded to Mr. J. Smith with *Louise Bonne of Jersey*. For dessert Apples Mr. Iggulden, gardener to R. B. Wingfield Baker, Esq., Orsett Hall, was first with *Red Astrachan*, the majority of the opposing dishes being unripe. A fine clean dish of *Lord Suffield*, staged by Mr. Bones, gained the first prize for kitchen Apples. The Judges, however, preferred appearance to weight, as there were many heavier dishes of good varieties unnoticed. Plums were staged in comparatively small numbers. *Magnum Bonum* and *Pond's Seedling* were the best kitchen, and *Coe's Golden Drop* and *Jefferson* the best dessert varieties.

Vegetables were staged in very good condition both by the gardeners and cottagers, though in smaller quantities than usual.

For a collection of nine dishes in the gardeners' section Mr. Iggulden was a good first, and Mr. C. Bishop had a similar award for six dishes. For a collection of three dishes of kidney Potatoes Mr. Iggulden was first, and also for three dishes of rounds; for the former staging good examples of Lapstone, Prince Arthur, and Snowflake, and the latter Model, Carter's Main Crop, and Schoolmaster. Celery was fairly good, but scarcely solid enough to be entitled to the awards. Mr. W. Harrington was first. Mr. Carver was first in the class for autumn-sown Onions with a very ugly lot, weight being the only recommendation. The spring-sown were very good, Banbury Improved being the favourite. Mr. Walker, Sherfield, was first. Mr. Quennell was first for Cucumbers with Tender-and-True. For Tomatoes Mr. Farrance, nurseryman, Chadwell Heath, was first with a remarkably fine dish of Trophy Improved, which was undoubtedly one of the best exhibits in the Show. This variety resembles that sometimes exhibited under the name of Stamfordian.

Farmers' produce was also well and largely shown, especially for the cups presented by Messrs. Sutton & Sons, Reading, and Messrs. Carter & Co., High Holborn. The Show was well arranged and highly creditable to Messrs. Earchy & Haws, the Secretaries, and it was also well attended.

THE WARS OF THE ROSES.

I HAVE waited a week to see whether anyone would answer Canon Hole's letter under the above heading on page 183, complaining of the place to which I assigned him in the Rose contests. No one having done so, I think it is only fair to myself to say that I had good reason for giving him the third place, and that in doing so if I erred at all it was on the side of generosity. I have grown and shown Roses now for eight years, and have never missed a Crystal Palace, South Kensington, Alexandra Park, Hereford, or Exeter Show, and I never yet saw Mr. Hole win a first prize. It is true I have not been so far north as Manchester, where Mr. Hole has won first prizes; but as one swallow does not make a summer, so gaining a prize at one show does not make Mr. Hole the premier exhibitor.

It is not a very edifying occupation to blow one's own trumpet, but when anyone does so it is as well to have good cause for doing it.

If necessary I can quote the number of prizes Mr. Baker has won in the eight years I mention; but I may merely say now that in two years he swept the board at the Crystal Palace—i.e., took every first prize, and that he has repeated the same feat at Exeter and Hereford.

If it comes to a matter of first prizes at grand shows during the last ten years, I could name other amateurs who are far before Mr. Hole; but in placing him where I did I was treating of the metropolitan shows of the National Rose Society, at which he has twice secured, not the first, but the third prize.—WYLD SAVAGE.

WORK FOR THE WEEK.

HARDY FRUIT GARDEN.

LITTLE requires to be done in this department at this time of year except attending carefully to the ripening fruit. Wall trees should be examined every morning, and all Peaches, Nectarines, and Plums should be removed as soon as ripe; they are improved in flavour by being kept for a few days on padded shelves in a well-ventilated fruit room. Figs ought to be allowed to ripen fully upon the trees, unless they have to be sent a distance, when they should be gathered before becoming over-ripe. Early Apples and Pears are deteriorated by remaining too long upon the trees, they having a tendency to become mealy and deficient in flavour, while if gathered too soon the fruit will shrivel; they, as a rule, should be left upon the trees until indications of ripening set in, and should then be gathered and placed in an airy fruit room to ripen. A few fruits gathered daily, weather permitting, will tend to prolong the supply. Nothing tends so much to prolong the season of early Pears as having a tree or two of the same kind upon different aspects. Jargonelle, for instance, upon a south wall will be in a fortnight before those from trees in sheltered situations in the open, or a week or more before those from trees against an east or west wall, and those from trees against a north wall will follow. Similar remarks apply to Williams' Bon Chrétien, Marie Louise, &c., that are not of long continuance. All kinds of fruit that it is found necessary to keep upon the trees for some time, either from not being ripe or to prolong the season, such as Morello Cherries, late Peaches, Coe's Golden Drop and Blue Impératrice Plums, should be netted up; and if wasps are troublesome cover the trees with hexagon netting, and hang bottles in front of the netting half filled with sweetened beer. In gathering Apples and Pears some experience is necessary to do it at the proper time. As a rule, the fruit is fit

to be gathered when it parts readily from the trees by gently raising or inclining it so as to exert some little pressure upon the footstalk. Great care must also be taken in gathering the fruit so as not to bruise or injure it in the least degree, or it will not only not keep well, but will be spoiled in appearance. Any pecked or otherwise damaged fruit should be separated from the sound and employed for present use. Go over for the last time bush, pyramid, espalier, cordon, and wall trees, removing all unnecessary shoots so as to give the ripening fruit the full benefit of sun and air and to mature the buds for future bearing. Let the shoots of wall trees be securely nailed or tied-in, as they often suffer much injury from the autumn gales.

Autumnal Raspberries are exceedingly useful for giving flavour to Red Currant tarts; they also make a nice addition to the dessert. Notwithstanding that there are plenty of worms, the birds are just as fond of Raspberries in October as in July; therefore nets must be employed. Every garden should have a row or two of October Red and October Yellow planted in an open yet sheltered situation in soil moderately light and well enriched. Hints on cultivation will be given in due time.

The Lawton Blackberry is worthy of more extended culture, giving, as it does, an abundance of fine fruit for tarts or jam in late summer and autumn. The old fruiting canes should be cut out so soon as the fruiting is over, and the growth of this year's production moderately thinned out—i.e., the weakest and least unripe shoots, retaining the strongest for future bearing.

ORCHARD HOUSE.

Late Plums, Peaches, and Nectarines should be placed together, so that they may be syringed until the fruit commences ripening, when it must be discontinued until the fruit is all gathered, when the trees may be placed outdoors, and syringed every evening if the weather be dry. If the trees are infested with aphides, red spider, or other insects, apply some approved insecticide. Dryness at the roots must not be allowed, or the bloom buds will fall off. The ventilators should remain open day and night, with hexagon netting over them so as to exclude wasps and flies, but in windy weather the ventilators should be wholly or partially closed.

FLOWER GARDEN.

Roses are seldom attended to in late summer with abundant supplies of liquid manure, hence they do not perfect good blooms, the leaves falling prematurely from poverty at the roots. If well attended to they will afford good blooms for some time to come, the weather being propitious. All long sappy growths should be cut back so as to prevent them being injured by the autumn gales, and if ripe shoots without the eyes started be inserted under a north wall they will root freely, more especially if covered with handlights until a callus is formed. All climbing Roses should have the old weak wood cut out and the young growths trained-in rather thinly, so as to expose them fully to light and air and insure their thorough ripening. Exceptions are the old Banksians, which for affording cut blooms in spring are very valuable, but it is rarely they are seen showing anything like the flowers they are capable of producing. They flower on the short medium-sized wood; therefore any shoots having a tendency to grow beyond a foot in length should be cut clean out, leaving only sufficient of the medium-sized growths that can be fully exposed to sun and air with a view to their being well matured.

Violas are very useful for bedding, particularly in wet seasons. Cuttings should now be inserted in rather light soil upon an east border, selecting the cuttings from the best of the plants, making the soil firm about them, and giving a good watering. Vestal, White Swan, Mrs. Henry Pease, and Lady Gertrude of whites; Blue Bell, Royal Blue, Perfection, and Holyrood of blues; Crown Jewel, Corisande, and Lutea grandiflora of yellows; Lilacina, The Lady, and Rubra lilacina of lilacs, are all fine. They are very suitable for cold moist localities.

Bulbs for Outdoor Planting.—Now is the time to secure them so as to have them in readiness to plant as soon as the beds are cleared of their summer occupants. In addition to Hyacinths, Tulips, &c., which are employed for grand displays, we will mention a few that should be found in every garden on account of their value for cutting. In Narcissuses, biflorus, poeticus single and double, Bulbocodium, Incomparable, and Sulphur Kroon, single Campernelle, and single sweet-scented Jonquils, Triteleia uniflora, English and Spanish Irises both in great variety; Iris reticulata, Allium azureum, A. aureum, A. neapolitanum, A. triquetrum, Alströméria aurea, A. psittacina, Anthericum Liliago, A. Liliastrium, Scilla nutans and vars. alba, rosea, and rubra, which though only varieties of the Wood Hyacinth are very desirable; Anomatheca cruenta, Gladiolus blandus, communis albus, Byzantinus, cardinalis, communis rosens, insignis, Colvilli and var. albus, all of which should be planted forthwith 4 to 6 inches deep, and they will go increasing in size and beauty from year to year.

PLANT HOUSES.

Greenhouse.—All hardwooded plants must at once be placed in their winter quarters. Boronias, Phenocomas, Tremandras, Pimeleas, and Gompholobiums should have the lightest positions, which with Leschenaultias should have a night temperature of

45° to 40° from fire heat. Epacris and Eriostemons will bear a lower temperature, but 40° to 35° at night should be a minimum. Elevate the whole near the glass, and do not crowd them, but so arrange them that light may reach to the base of the plants. Heath generally, if no separate house for them be provided, should be placed at the coolest end of the house, so that by giving more air at that part their requirements may be met.

Azaleas that flowered early and were started into growth at once will be full of buds in a forward state, and should be kept in a cool airy house with plenty of light, from which they may be draughted as required to gentle heat, in which they will soon expand the flowers. A. Borsig, Fielder's White, Narcissiflora, amona, Flag of Truce, Raphael, Queen Victoria, and Vittata elegans are fine for early work. They should not be closely tied; indeed, for forcing to cut from they require very little tying. Late-flowering plants should be at once tied into form, for if done now the points of the shoots assume their natural upright position before flowering, which would not be the case if the tying is deferred until the wood has become hardened.

Camellias should, if placed outdoors (not a good practice), be taken in before heavy rains or frost occur, either of which are sufficient to cause the buds to fall. The buds if very thickly set must be thinned to one, or at most two to each shoot. Those plants with the buds advanced and required for early flowering may, if wanted to flower early, be placed in a house having a temperature by artificial means of about 50° with moderate moisture, but there must be no great increase of temperature over that of an ordinary greenhouse, or the buds will in all probability fall.

Hyacinths, Narcissus, Tulips, and Crocuses should be at once secured and potted. Sound instructions were given last week, and are continued this week, by Mr. Moorman relative to those popular flowers. Chrysanthemums must be at once staked and trained as soon as possible. The flower buds should be thinned and liquid manure should be liberally given to the plants. Cyclamens should be kept near the glass and have every encouragement to make a good growth. They are the better of gentle warmth—50° by artificial means.

Violets intended to be placed in frames should be at once taken up with balls and planted in turfy loam with a fourth of well-decayed manure and a like quantity of leaf soil. The situation for the frames should be a sheltered one, and if the foliage of the plants be about 9 inches from the glass all the better. Any old yellow leaves may be removed, but avoid trimming off any green leaves. Firm the soil moderately about the roots, and give the plants a thorough watering. The lights need not be put on until frost or heavy rains set in. Pot a few dozen plants of such as Victoria Regina, New York, and De Parme, employing the compost above named, placing them in a shady position for a few days, and when established they may be placed upon shelves under glass, where they will receive plenty of air and have a night temperature of 45° to 40°. They will flower freely, and are useful for disposing indoors on account of their agreeable perfume, besides affording flowers when plants in frames are bound-up by frost and snow.

TO CORRESPONDENTS.

BOOKS (Juvenile).—There is Harvey's "Flora Capensis," which is a large book, and perhaps more than you want; but there is also a synopsis of it in a portable form which might suit you. We do not know who is the publisher of the latter; we rather think it is published at the Cape.

GLASS FOR VINERY (T. B., Hartlepool).—We should use the 21-oz. glass which will answer admirably for glazing the roofs of your vinery and plant house.

MANURING FLOWER BEDS (Rector).—Your beds now occupied with Geraniums, and to be planted with bulbs this autumn, again to be occupied with Geraniums next summer, should have a good dressing of very much decayed manure before the bulbs are planted, digging it in deeply so as not to be in actual contact with the bulbs. Wood ashes or burnt refuse of any sort might be advantageously applied in addition to the manure, also sand or gritty matter if the soil is at all heavy. If the beds are well enriched for the bulbs no manure will be requisite for the succeeding crop of Geraniums.

CLIMBING ROSES FOR CONSERVATORY (Verax).—We shall shortly publish notes on this subject from a successful cultivator.

GRAPES DECAYED (R. W. B.).—The berries sent are quite decayed and covered with fungus. They not only suggest that the roots of the Vines are in wet ungenial soil—sour and stagnant, but that the temperature of the house is too cold and the atmosphere too close and moist. In a marshy position such as you describe, the Vine border ought to be formed entirely above the general level of the ground. The Vines inside should be trained thinly, the rods being not less than 3 feet 6 inches apart, the laterals being 18 inches apart on both sides of the rods, and the Vines 18 inches from the glass. It will be easy then to secure ample yet uncrowded foliage. The temperature at this period of the year should never be below 60° with ventilation. You do not state the age and condition of growth of the Vines, so that we are unable to state whether or not lifting the roots would be advisable.

PASSIFLORA CASTING ITS FLOWER BUDS (Corbie).—It sometimes is the result of over-luxuriance, the supply of water to the roots not being commensurate with the growth. We find the best remedy is to top-dress with rich compost—turf loam and horse droppings in equal proportions. This attracts the roots to the surface. We water liberally after the buds show, and train the shoots rather thinly and near the glass, so as to have

the growths solidified. When the shoots show flower they ought to be allowed to hang down. If the top-dressing would be an objection apply weak liquid manure, 1 lb. guano to twenty gallons of water, and apply it in such quantity as to thoroughly moisten the soil.

EXHIBITING FERNS (J. S.).—*Adiantum Capillus-Veneris* magnificum would, we think, be admissible in a collection of British Ferns.

MANAGEMENT OF FIGS (G. C.).—When Figs are grown out of doors or in an unheated house all attempts to produce a second crop should be checked by pulling off all the little fruits as soon as they are sufficiently large to get hold of. The tree will then make another effort at fruiting along the whole length of the current year's growth, and the chances are that the embryo fruit—that which would be the third crop in a favourable climate—will just advance to the right stage for remaining dormant through the winter. The point to aim at is to have in autumn before the fall of the leaf the greatest possible quantity of little plump buds about the size of a Radish seed on thoroughly ripened wood. You can do some good now by pulling off the fruits immediately, especially if the autumn remains favourable, but the results would have been better if they had been kept pulled off as fast as they formed.

SELECT GOOSEBERRIES (A. M. G.).—*Green:* Green Gascoigne, Green Overall, Green Walnut, Heart of Oak. *Yellow:*—Early Sulphur Rockwood, Yellow Champagne, Broom Girl. *Red:* Ironmonger, Keens' Seedling, Red Warrington, Turkey Red.

TO DESTROY GOOSEBERRY CATERPILLAR (J. P.).—Place a thick layer of spent tan from the tanyard 2 or 3 inches thick all round your Gooseberry bushes and dig it in in the spring. This is an excellent preventive of caterpillars.

DISEASED PEACHES (Hon. Mrs. H. Freake).—The Peach is attacked by a fungus called *Oidium fructigenum*. It has been very prevalent this season, and is no doubt, attributable to atmospheric influences like all fungoid diseases in plants. We do not know of any remedy for it unless it be sulphur. The leaves are perfectly healthy.

BOAT HOUSES (Capt. Callaghan).—We do not know of any work that treats on the erection of boat houses. Perhaps you may find something on the subject in works on rural architecture, but we are sorry we cannot assist you.

MALFORMED GRAPE (H. Brace).—A Tomato could not impregnate a Vine; still we are not surprised at your conjecture, for the berry you enclose has the shape of a Tomato. This is caused by the union of two or more ovaries, the various sutures causing the resemblance alluded to.

DISCHARGED GARDENER (J. T.).—If you have misconducted yourself and your employer has in consequence discharged you, you cannot claim a month's notice or a month's wages.

DRAINING GARDEN (E.).—Your best plan will be to dig a few trial holes quite 3 feet deep, having them covered and so protected that surface water cannot drain into them. Let them remain during the winter, and if no water collects in them your soil will not need draining. The fruit shall have our attention.

ARALIA JAPONICA (R. H. A.).—It is hardy in the south of England. Your shrub may be safely transplanted early in November if proper care is exercised during its removal.

RED CABBAGE BURSTING (Alex. Doyle).—The only remedy is to cut them or take the plants up and lay them in by the heels in an open shed in moist soil, though lifting and laying-in with the heads to the north would act as a check to growth, and to some extent would lessen the evil.

THRIPS ON FERNS (G. Barrack).—The frod sent us shows abundant evidence of thrips, which undoubtedly are the cause of the spots. Fill the house with tobacco smoke upon two consecutive evenings, and repeat the process in a week. It is necessary that Ferns have the fronds dry when fumigation is practised, and that the house be no more than filled with smoke so that the plants cannot be seen from the outside through the glass; the fronds will be injured by an overdose of smoke, and an under one will not destroy the pests.

CLIMBERS FOR GREENHOUSE FERNERY (S. Fisher).—*Plumbago capensis*, *Habrothamnus fascicularis*, *Lapageria rosea*, *L. alba*, *Passiflora Comte Nesselrode*, *P. Imperatrice Eugenie*, *Tacsonia insignis*, and *Bignonia jasminoides splendida*, are all suitable. We presume that you require them for affording shade to the Ferns, which is required from March to October. *Lygodium scandens* is useful for clothing pillars, &c., and *Ficus repens* for covering walls.

STOCK FOR MRS. PINCE GRAPE (J. Gilchrist).—White Lady Downe's would answer as a stock for Mrs. Pince, the stock being strong and healthy. Mrs. Pince, however, does well upon its own roots.

VINES IN POTS (Norwich).—There is no reason why you should not fruit the Vines now in pots by planting them out in a bed or border. All that is necessary is to turn them out with the ball entire and ram the soil well around them, forming a dish at the surface around the cane as far as the ball extends, to make sure of the water passing through the ball and thoroughly moistening it until the roots are working freely in the surrounding material.

CYCLAMENS (E. R.).—It is not easy to determine the Cyclamen flowers without the leaves. The pink one is evidently *C. europæum*, and the larger white one *C. hederæfolium album*. If you enclose flowers and leaves, with a stamped envelope enclosed with your address, and send it to James Atkins, Esq., Painswick, you will no doubt obtain the desired information.

HEATING VINERY (Lancashire Surgeon).—As you do not intend forcing the Vines you will not require more than two rows of 4-inch hot-water pipes, which should be raised about 9 to 12 inches above the border, and about 3 feet from the front wall, having them alongside each other. We should have an improved saddle boiler of 3 feet length fixed in a shed at the back of the house, taking the pipes across one end of the house and then along the front. The flow pipe must rise from the boiler to the point whence the return is made to the boiler, and from that point the return pipe must decline; but if it has the same incline as the flow pipe until it reach within a few feet of the boiler it will be sufficient, being taken down by an elbow to join the return socket of the boiler. At the highest point in the pipes must be an air pipe, and taken to the upper part of the roof with its end curving downwards; if taken outside all the better. In the shed over the boiler you will need a water cistern, with a supply pipe to the return pipe or lower part of the boiler, the water in the cistern being just high enough to three-parts fill the pipes at the highest part with water when cold, the supply

to the cistern being regulated by a ball-tap, and the supply pipe to the boiler having a check valve so as to prevent the water flowing up the supply pipe and running over by the cistern. Any horticultural builder could supply you with the materials, and they could be fixed by a bricklayer and handy smith, or the person supplying the materials would undertake to fix them. We cannot recommend tradesmen, but any advertising in our columns would serve you satisfactorily.

EDGING PLANTS (*H. E. B.*).—The following are good edging plants:—*Ajuga reptans rubra*, dark purple leaves; *Arabis alpina variegata aurea*, *Aubretia purpurea variegata*, *Cerastium tomentosum*, *Eunymus radicans variegatus*, *Iberis semperidorens fol. var.*, *Sedum aurea variegata*, *Sempervivum californicum*, *Stachys lanata*, *Stellaria graminea aurea*, and *Thymus citriodorus aureus*, all of which are hardy. The following are more or less tender:—*Iresine Lindenii*, *Peristrophe angustifolia aureo-variegata*, *Sedum Sieboldi medio-picta*, *Mesembryanthemum cordifolium variegatum*, *Guaphalium lanatum*, *Santolina Chamæcyparissus*, *Leucophyton Brownii*, *Alternanthera* in variety, *Echeveria secunda glauca*, *E. pumila*, *Alyssum variegatum*, with *Lobelias* and Golden Feather *Pyrethrum*.

TRANSPLANTING CAMPANULAS (*Idem*).—The plants would receive a slight check by transplanting, but if done carefully they would speedily recover. They may be moved now, but preferably in early spring.

ROSES SHEDDING THEIR LEAVES (*Idem*).—There are spots of mildew upon the leaves, induced by drought and poverty of soil. Manure well, and in future seasons water copiously in dry weather with liquid manure after the buds show, mulching the surface with short manure.

COURT-PENDU-PLÂT (*C. H. Lucas*).—The Apple and its name are both French, and the latter signifies the Short-hung Flat, from the very short stalk and the flat shape of the fruit. It has no reference to plate.

ERRATUM.—The *Araucaria imbricata*, referred to last week on page 208, is in the garden of Mr. Bousted, Settlebeck, Sedbergh, Yorkshire; not "Mr. Dousted, Jedburgh," as printed.

CANNING TOMATOES (*H. Camps*).—A simple and usually satisfactory way of canning tomatoes is to pour boiling water over a desirable quantity of ripe tomatoes to loosen the skin; let them lie a few minutes, peel them, draining well first; cut out all green places, then set on the fire, and after they have commenced boiling boil for fifteen minutes. Have your cans ready and very hot, fill full, and seal each one immediately as it is filled. Some prefer to boil the tomatoes till they seem almost dry; others, again, claim that merely scalding them is best, and that they taste fresher when merely brought to the boiling point.

NAMES OF FRUITS (*C. & Co.*).—40, Doyenné Boussoch; 55, Flemish Beauty; 57, Bellissime d'Hiver; 81, Jersey Gratioli; 77 and 111, Not known. (*T. S.*)—1, Formosa Nonpareil; 2, London Pippin; 3, Nelson Codlin; 4, Not known; 5, Not known; 6, Trumpington. (*W. D. Paine*).—20, Winter Hawthornden; 25, Christie's Pippin; 33, Not known. (*H. Loftus, Tottenham*).—It is an American Grape, called Isabella. (*Connaught Subscriber*).—Poire Pêche. (*H. H.*)—1, Green Yair; 2, Hesse Pear; 3, Beurée Capiaumont; 4, Irish Peach. (*G. Kent*).—1, Not known; 2, Newtown Spitzenberg; 3, Flower of Kent.

NAMES OF PLANTS (*Mrs. L.*).—It is the common Reed Grass (*Phragmites communis*). It will do in any damp place, and if you have not such an one you might make a small tank, which might be kept full of water, or an old tub sunk in the ground would answer the purpose. (*M. G. J.*).—1 and 3 are both varieties of *Begonia Pearcei*. No. 3 is very good. No. 2, *B. Weltonensis*. (*Flowering Shrub*).—*Lycyesteria formosa*. (*A. F. G.*).—*Polygonum Sieboldi*. (*S. W.*).—*Adiantum petatum*, a beautiful Fern, but rare. It thrives out of doors in the southern counties, but is best when grown in a greenhouse. It is a native of North America.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

THE CULTIVATION OF WHEAT.

WHEAT must still rank as the most important of the cereal crops upon the home farm. Sometimes barley or even oats may realise almost as much money per acre, but wheat is considered as being the rent-paying crop. This matter is at the same time a question of soil, because some of the light and kind soils are in some respects better adapted for a rotation, which places the barley crop in a more favourable position than wheat. The cultivation of wheat affords a wide field for practical illustration, this cereal being grown successfully upon nearly every kind of soil where the climate is favourable; but the management of the land will require systems of cultivation as dissimilar as the soils. We therefore propose to refer to the tillage and rotation of the different soils separately, selecting first the heaviest strong clay land and the cultivation requisite for the successful growth of wheat thereon. Upon many heavy-land farms formerly very little live stock was kept, but since we have to contend with the whole world in the sale of wheat it is found best not to depend entirely upon the cereal crops. The old long fallow may be dispensed with, except in cases where the land is foul with couch or water grass; and when steam power is not available upon the home farm, and horse power only is used, the long fallow is a very expensive and tedious process. The rotation, however, upon which the land is cropped will have its effect in diminishing the horse labour if the old rotation is given up—viz., first, fallow;

second, wheat; third, oats or barley; fourth, clovers; and the following rotation substituted—first, autumn fallow seeded to green crops fed by sheep, and roots to be pulled; second, wheat seeded to clover; third, clover; fourth, oats or barley; fifth, beans and peas; sixth, wheat. Now in this six-course rotation, which we approve, each crop is a good preparation for the other; and there are various opportunities for cleaning the land between them, and also the capability of feeding sheep on green crops in the summer months, and furnishing at the same time a supply of mangolds, &c., for feeding purposes at the homestead. It will be noticed that by this system one-third of the land will produce wheat, one-third Lent corn and pulse, and the other third part clover, green crops, and roots in each year. This we consider the most valuable rotation, except upon some strong soils in certain districts of the kingdom upon which wheat and beans constitute the customary mode of cropping, but involving at the same time a liberal application either of yard dung or artificial manures to be successful.

Upon some strong clay lands, and especially those which have not been thoroughly tile-drained, a long fallow once in four years affords the only opportunity of rendering the soil capable of growing the usual crops; we will therefore describe the mode of making the winter and summer fallow in preparation for wheat. Immediately after harvest, whether the land is after clover or a pulse crop, it is sure to have a considerable amount of the water grass running over the surface, and even if the land is fairly clean the nature of it renders the fallow requisite. It should first of all be scarified with a Coleman's implement—that being the best for hard ground—both lengthwise and crossways, then harrowed, rolled, &c., and the grass and weeds carted away; the land should then be deeply ploughed, say not less than 6 or 7 inches in depth, and be properly water-furrowed so as to carry off all surface water during the winter. If steam power is available the same process may be observed both of scarifying and ploughing to lie during winter; but we cannot recommend that steam ploughing should be done deeper than the horse ploughing, because it brings to the surface a host of weed seeds which it will take years to eradicate, and which should have been allowed to lie dormant in the land. The deeper ploughing further necessitates either extra chalking or liming at heavy cost. Having laid the ground up for the winter in order to receive the alternation of rain and frost, so essential to the amelioration of those soils now under consideration, it will be necessary in the spring after the Lent corn sowing is over, to attend to the fallows by ploughing back the ridges. This will destroy one crop of weeds in their infancy; then, instead of working the land by harrowing, rolling, &c., we recommend (as we are now writing for the information of the novice) that the land after about a month should be cross-ploughed. The object of this is to bring it perfectly level when worked down, because in the cross-ploughing without previous dragging, &c., the land being rough and cloddy drives before the plough. If the work is done about a month after the cross-ploughing the land will have been thoroughly aerated, and will often have in favourable seasons killed the water grass, together with another crop of young weeds. The fallow as soon as worked down will now be producing young weeds again in abundance, and its subsequent working will depend upon the time of year. If August has come it will not be necessary to cross-plough again, but only scarify and harrow. The land should then be veered out according to the size of the lands required at seed time, and the dung spread or guano be sown between the veerings. The land may then be ridge-ploughed in the first week of September, and allowed to lie and become stale and mellow for the reception of the seed, which in the strong land should not be sown later than the first or second week in October; and as at that time of the year the land may be wet and heavy to work we advise the ridges to be made five turns or 8 feet wide, in order that the drill may take a ridge at once; the wheels and the horses drawing the drill will then go in the furrow only. The same with harrowing: the horses will keep in the furrows without treading the land, so important in heavy clays.

The quantity of seed we recommend is two bushels per acre at the early season; should, however, the seed time be delayed until the late period of November three bushels should be sown, because we have to consider the numerous enemies to the young plants, besides the possibility of some seeds perishing. In drilling wheat on this strong soil the width of the rows is important. They should be 12 inches, or only eight rows upon the ridge; no seed need then be sown in the furrows. This width of drilling is one of the principal features in the whole process of cultivation for wheat in heavy land, because such soils are usually infested with crowfoot and some other weeds; and further, after a very backward spring the wheat plant will often look yellow and sickly, in which case it is not only desirable to destroy the weeds but to move the land with the horse hoe, and thus give the plants more vigour, and enable them to show a deep green colour so essential to the crop. This can only be done effectually by wide drilling; it is the only safeguard to the crop. When drilled at 6 or 7 inches it may be hand-hoed, and this would kill some of the weeds, but the hand hoe will not move the surface enough to resuscitate

unhealthy wheat plants. When wheat is drilled upon these small ridges it is of great consequence that the land should lie rounding, with a gradual fall from the centre of the ridge to the furrow on each side; and to finish off the work after drilling it is best to strike the land furrows with the double mould plough, and after the water furrows are struck out with the common plough they should be carefully made out with the spade, taking care to have them from 2 to 3 inches deeper than the land furrows. This will clear the water out well from the land furrows. Still it will be necessary, particularly where the land is flat, to have the water furrows looked over and made out the second time, immediately after the first heavy rains which occur after drilling the wheat.

It is of consequence that the sort of wheat for seed should be chosen as best adapted to the soil. We do not approve of any sort of white wheat for heavy land, except where the climate is especially early and favourable, but prefer the best varieties of red wheat, such as Nursery, Golden Drop, Browick, and the Red Lammis. These all yield well on the strongest soils.

The foregoing remarks as to the use of horse power refer only to those home farms where only about a hundred acres or less are under cultivation, but on larger occupations we much prefer the use of steam power, not only on account of its better effect on the land, but so much may be done in a short time whilst the weather is favourable. It is highly desirable where the business is of sufficient size and importance to have locomotive steam power available, not only for tillage purposes, but also for thrashing, and a house for the steam engine should be attached to the buildings on the farm, so that in the winter months the engine will not only be protected and cared for, but will be set to work and give its power for the purposes of chaff-cutting, cutting roots, cracking cake, and grinding of corn. The engine house, being properly placed near the building where the above work is required to be done, should be so constructed that the floor should be grooved to receive the wheels upon a slight incline, and when in position to be blocked and made firm in its place ready for all usual work.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—This will now be required to prepare the land for the sowing of trifolium if not already finished, also for rye and winter tares. Should the weather continue favourable all speed should be made in autumn fallowing or cleaning of the land intended for next year's root crops, the last ploughing being left to be done after the wheat is all sown. Some ricks of wheat as well as of barley may now be thrashed by steam power, and the corn sold and delivered. The horses will require oats, so that a rick of these may well be thrashed and the corn stored in granary ready for daily use. Some farmers object to new oats for horses, but it is now so common to grow barley in admixture that the corn is good for feeding farm horses much earlier than when oats are grown alone. In some of the late districts the horses will still be employed in carting late crops, such as oats, spring beans, &c. The odd horse will be employed in horse-raking the stubbles, the proceeds being useful for feeding pigs, poultry, &c. Clover this season is giving in some cases a third cutting, which will be carted daily to the homestead, and as soon as the clover leas are cleared the young clovers in the stubbles are as flourishing this autumn as likely to afford a fair cutting, so that the feeding of cattle may be continued with advantage until the early frosts commence. Many farmers hesitate cutting the young seeds, but we find that the clover when cut comes better in the spring than it does after sheep-feeding, for these animals are apt to bite out the heart or centre buds of the plant, whereas when cut with the scythe the centre buds of the plant are left entire and uninjured.

THE AGRICULTURAL HALL POULTRY SHOW.

THINGS seem coming round to what we have long foreseen and predicted. A large number of poultry shows have fallen through or are about to do so, and those which are continued will be all the better for it and all the more appreciated. Their number, especially in or near the metropolis, had been multiplied beyond all reason and the demand for them. The only result of this was discouragement to committees, who found their schemes financial failures, and injury to birds, which were overshadowed. We are not, therefore, at all sorry to see that of the four metropolitan or quasi metropolitan shows two alone are to take place this year—viz., the Agricultural Hall and Crystal Palace Shows. The schedule of the former is before us. There is a particular point in the continuation of this Show, inasmuch as it is connected with the Dairy Show, and is consequently much helped by thousands of visitors who come principally to see the latter. It is an advantage, too, that those who are really interested in all connected with the dairy should have their attention invited to poultry.

The Show is to be held on October 10th, 11th, 12th, and 14th, thus including a Sunday—far too long a time for chickens, especially in a building, well adapted as it is to the purpose, probably much crowded and lighted daily during many hours by gas. We

have reason, however, to hope that this year precautions will be taken against the birds suffering from its noxious fumes. We are glad to see in the rules signs of the influence which is beginning to be brought to bear upon shows by a body of fanciers who have united to discourage all fraudulent practices. In rule 6 we read, "Any exhibitor detected in fraudulent practices shall forfeit all or any prizes or cups that he may have had awarded to him at the Show. No entry fee in such cases will be returned." And again rule 7, modelled on one of the Poultry Club rules, is good—"All protests against awards must be lodged with the Secretary within six hours after the termination of the judging, and must be accompanied by a deposit of £1. Such protests will be submitted to the Committee of the Poultry Show, who, after hearing the decision of the Judge or Judges thereupon, will decide as to whether such protest is frivolous or made without due ground, in which case the deposit will be forfeited." The only omission seems to be that it is nowhere stated who the said Committee of the Poultry Show are.

The classes for poultry are sixty in number with twenty-one cups; those for Pigeons fifty-seven with nineteen cups. To nearly all of them there are three prizes of £2, £1, and 10s. each. In a few of the poultry classes there are four prizes, the first in these cases being of the value of £3. Dorkings have five classes, Cochins four, Brahmas five, Game six, Ducks five (there being one for Pekins), Langshans four, with three cups and an "oriental prize." The cups in these classes are confined to members of the Langshan Club. We do not like this system, which makes it possible for the chief distinction to go to inferior specimens. Such clubs should confine their private competition to private exhibitions if they cannot afford to throw open their honours. In Pigeons Pouters have four classes; Carriers eight, one being a champion class; Dragons thirteen, one a champion class; Tumblers six; Jacobins three; Owls a champion class and four others; Turbits three, one of them for young birds; Antwerps three.

We wish all success to a Show got up on so magnificent a scale.—C.

THE JUDGES OF THE BATH SHOW.—In my account last week of the Bath Poultry Show I mentioned one Judge only—viz., Mr. Hodson, not being aware that there was a second Judge of the fowls. In the catalogue there was a hint as to another, and only a hint, for there was printed after Mr. Hodson's name, "Mr. ——" So as I imagine the services of another Judge had not been secured when the catalogue was in the printer's hands, and I did not chance to hear that Mr. Blank had become more than a blank. I have, however, had a letter from Mr. G. Saunders Sainsbury of Devizes, saying that he judged the Game, all the Hamburghs, Bantams, Ducks, Any other variety classes, and any other variety Selling classes. I must say that I am pleased to find that Mr. Sainsbury is again among the poultry. Many of the old readers of this Journal who remember not only the frequent occurrence of his name in the prize lists, but his articles on poultry, particularly on Black Ducks, would be glad to hear that not only was he acting as Judge, but was once more a breeder and exhibitor.—WILTSHIRE RECTOR.

THE STEWARTON HIVE.

"HIGHLY COMMENDED," and deserves more than "honourable mention." Some time last year I noticed this hive very prominently, and in doing so quoted from Mr. Hunter's book a long paragraph from the pen of the "RENFREWSHIRE BEE-KEEPER," wherein his mode of managing it is unfolded. Since then this hive has been frequently mentioned and commended in the pages of this Journal. Notwithstanding all that has been said in its favour during the last twenty-five years it is not well known by bee-keepers generally, and is seldom met with. Why it is not more widely spread and generally used I cannot say. It is a good hive and should be well known, and therefore I shall endeavour to give as plain and understandable a description of it as I can, with a view to point out its best and most commanding features.

But let me first say that the Stewarton hive of to-day is not what the Stewarton was ten years ago. Formerly this hive had a crown board with two narrow holes or slits in it for supering purposes. These narrow holes were about half an inch wide and 4 inches long, cut out of the crown board near its outer edges, away from the brood nest. This was said to be one of its distinguishing advantages—that is to say, the queen never found her way to the super through these side and narrow entrances. If the Stewarton hive was right then it is wrong now, for it has now no crown board at all, and the queen can go into the super as often as she pleases without hindrance. The narrow slit was of no advantage whatever. The removal of the crown board to give the bees free access to the super is a very great improvement to the Stewarton. The less complication the better.

The Stewarton hive is made for work and not for appearance. It is unlike all other kinds of hives, and does not possess one feature of beauty. As it comes from the carpenter's bench it is a strange and unseemly contrivance. Two boxes, octagonal in

shape, 6 inches deep and 15 inches wide, with two honey boxes 4 inches deep, all with crossbars, make a Stewarton hive. They resemble a lot of empty American cheese boxes or a bundle of riddle rims. The two 6-inch boxes are fastened together, and the open spaces between the bars of the top box are closed with slides which run in grooves. In this way the bars and slides make a roof which answers for a crown board. When the first super is put on the slides are shifted from the top of the hive to the top of the super, and thus a storey is added to the house, with free access from both first and second floors to the attic. If a second super is used the slides are again withdrawn and placed at the top of the second attic, and so the slides are moved upwards by stages from hive to super, and from super No. 1 to super No. 2. Some of the hives are enlarged from below by adding a third 6-inch box. When put together and well tenanted it is a good hive capable of doing much work. It is chiefly used for supering, and the principle of the Stewarton hive is in advance of all other kinds of hives for supering, and this is saying a great deal for the Stewarton. In making this statement I wish to be fairly and well understood. I do not mean that the Stewarton hive will yield more super honey than other kinds of hives of equal strength, but that the connection of super and Stewarton hive is more close and intimate, if the expression is allowable, than in any other kind of hive known in England. The separation between hive and super in the Stewarton hive is hardly felt by the bees, and therefore they are less likely to swarm than in other kinds. In all cases of supering the great difficulty is to prevent bees from swarming. In many instances bees swarm with empty supers on them, and often swarms issue from hives with supers on them half filled. Even in the Stewarton hive bees cannot be prevented from swarming. They set queens and go off to form colonies. Neither care nor contrivance can prevent swarming at all times. Of all known practised systems of supering the Stewarton hive offers the greatest inducements to the bees to remain at home. Young folk will marry and bees will swarm despite all that can be done to prevent them; hence in all kinds of hives kept for supering we have suggested that the queens have their wings clipped. If the queens cannot go with the swarms the bees will return to their hives shortly after they leave them.

In managing the Stewarton experience has led practical men not only to the removal of the crown board and the introduction of slides, but the adoption of the non-swarming principle. Formerly an empty hive was filled with two or three swarms and supered the first year. Now we believe stock hives are supered as soon as they are ready, and every effort made to prevent swarming. My object in writing these notes is to give the readers of the Journal as fair and accurate a knowledge of this hive as I can, and commend the principle of it in the highest possible terms; and I trust that my simple commendation will induce many bee-keepers who are seeking super honey to adopt the Stewarton principle in the management of their bees. The advocates of the Stewarton hive confine the bees in winter to one box, and in spring give room as the bees spread out in bulk and multiply in numbers. One, and sometimes two, breeding boxes are added in spring to the winter dwelling house. Probably a little experience will lead to a modification of this practice, for it is invariably found that empty spaces in hives are, during the spring months, far too much filled up with drone combs. This fact can never be wisely contradicted or contraverted. It is a stroke of good policy to get stock hives of all kinds well filled with combs in autumn, whether managed on the swarming or non-swarming principle. Another point in the management of this hive I must notice—viz., the practice of keeping stock boxes for two or more years. I suggest the desirability of having the combs in the stock boxes renewed every season, and I am sure that this suggestion will in process of time be universally approved. All kinds of hives that have filled supers are pretty well stored with honey and bee-bread or pollen. The super-abounding pollen would be a hindrance to the bees if kept, and the honey if taken and sold would realise at least £1 per hive, and one-fourth of this sum would provide sugar-syrup enough to fill empty boxes with beautiful new combs and store them with healthy food for winter. Hives of all kinds thus filled make the best of all stocks, full of health and ever ready for work.

In complimenting the principle of the Stewarton hive I leave the hive itself and its faulty features or points for future consideration, because I wish to avoid all matter of controversy in this article. The principle of the Stewarton can be adopted in supering with straw hives or bar-framers. I have repeatedly told the readers of this Journal that by placing one bar-frame hive over another (after removing their crown boards) the Stewarton principle could be carried out with great results. If I were to adopt the Stewarton principle of supering I would only alter the crown arrangements of my capital and convenient straw hives. Let it be well and fully understood that a change of hives would not secure success. The principle of shift and thrift and a good knowledge of management will do more for bee-keepers than a change of hives. While I heartily welcome every real improvement in apiculture, and hold out to view the highest models, I

have ventured now and again to warn the bee-keepers of England against the beguiling influence of trumped-up novelties. To run after such is the shortest road to get rid of cash and secure failures in bee-keeping.—A. PETTIGREW.

OUR LETTER BOX.

RABBITS IN FIELD (W. H. H.).—You do not say what kind of Rabbits yours are, or what precautions you take against wet, &c. We do not think that Angoras or breeds of that nature would ever do in an open field, especially, as appears from your letter, if the grass is allowed to grow, although some of the hardier breeds might. We should say in the first place that the death of your young Rabbits is caused by too much wet food. In addition to this the bucks if loose, as they apparently are from your letter, would probably kill the survivors. Take the Rabbits out of the field if you want them to do well, and feed them with good corn, not bran, or at any rate a mixture of the two, and lettuce, young corn, and parsley are all better than grass. You are not the first who has tried the experiment and failed.

A STEWARTON HIVE.—In reply to "E. S." "A RENFREWSHIRE BEE-KEEPER" states that "Had stripes of embossed wax sheet been inserted in the hive as intended, the combs would have been wrought perfectly straight and parallel."

SUPERED HIVE (Horace).—As the supers which you placed on your hive are not filled they should now be removed. The hive which is filled with combs will make a good stock for next year. Give it a few pounds of sugar syrup as rapidly as the bees will take it, cover the hive well, and expect returns next season.

MR. FOX'S HIVE (Amateur).—We are not able to answer your question. Write to Mr. Beran Fox, Southernhay, Exeter, and you will no doubt obtain the information you require.

SUGAR SYRUP (H. C. Ripley).—Mr. Pettigrew's recipe for feeding bees into stocks is good soft sugar at 3d. per lb., boiled in water at the rate of 1 lb. of sugar to one pint of water. The sugar he is now using is of a light cream colour, and makes excellent syrup, from which the bees (twenty swarms) are building combs rapidly. Syrup made in such proportions of sugar and water is as sweet as the syrup of flowers when first gathered, and has also much substance or body in it. It is simply a good imitation of Nature's production, and is improved both in taste and substance by boiling. Some bee-keepers use less water, and probably it is better to use rather less than more water, as some sugars are much weakened by the refining processes through which they pass.

METEOROLOGICAL OBSERVATIONS.

REMARKS.

- 11th.—Very foggy in the morning, but afterwards fine and bright, though slightly hazy.
 12th.—Hazy in morning, very cloudy and overcast between 11 A.M. and noon, and again about 1 P.M., when there was a heavy shower and squall of wind; afternoon clear and bright.
 13th.—A splendid morning, not a cloud in the sky, quite like spring; afternoon rather cloudy; evening misty.
 14th.—Fine day, but occasionally cloudy.
 15th.—Very windy day, squall of wind and rain at 9.48 P.M.
 16th.—First part of morning very fine, but it clouded over about 10 P.M.; afternoon and evening fine and bright.
 17th.—Dull and overcast day, slight shower at 11.30 A.M., drizzling in the latter part of the afternoon; fair evening.
 Barometric readings rather above those of last week, but all the thermometric values below those of last week; in fact the weather has been much cooler, although there have been several bright days.—G. J. SYMONS.

COVENT GARDEN MARKET.—SEPTEMBER 18.

THE supply of Grapes from the Channel Isles is now beginning to fall off, but we are having a good quantity of Dutch, which are being sold at low prices. Foreign Pears arriving only in small quantities; good samples of home-grown are in more demand. Trade still very dull.

From observations taken near London during forty-three years, the average day temperature of the week is 64.9°; and its night temperature 45.5°.

ROSE ELECTION.

DECLARATION OF THE POLL.

WYLD SAVAGE" now calls the election "a mockery, delusion, and snare." Why? Because it does not agree with his preconceived notions. Was it likely—nay, was it possible, or even probable—that the collected opinions of thirty or forty different persons, however good and sound they might be as to the merits of the varieties of a given flower, when those varieties are so numerous as in the case of the Rose, could agree as regards forty-eight of those varieties? It is simply impossible. Five and thirty out of the forty-eight might have been allowed by all, and so far there would have been unanimity; but the remaining baker's dozen would have sadly taxed the powers even of "WYLD SAVAGE" in obtaining anything like a unanimous opinion. But it is this variety of opinion that gives zest to all our pursuits. And why, I ask, may we not have these differences of opinion without the results being "a mockery, delusion, and a snare?" Supposing an amateur asking the advice of our friend, stating that he intended to begin Rose-growing with a view to exhibition: surely "WYLD SAVAGE" does not mean to say that if he ordered the first sixty varieties as they appeared in last year's election, ten plants of each, and if he brought to bear on these the best soil and climate and the greatest skill in cultivation that could be obtained, this amateur would have been wholly out of the race in the battles of the past season because the plants thus ordered were altogether wrong, they were the worst varieties instead of the best; they were, in fact, nothing more nor less than "a mockery, delusion, and snare," and that to stand any chance in exhibiting Roses he must begin afresh—select the Roses that never obtain mention amongst the sixty best of the election, and that by these means he is likely to obtain in future contests the "double firsts" that he covets?

I give our friend credit for knowing better than this. He knows well that the other way would not pay, and that it would turn out a greater "delusion" than the election. Indeed I scan down (I have just done it) the list of last year's election, and though I might shift the position of our favourites according to my fancy, yet the bulk of them are right. The position, I have explained before, is most easily shifted by an eccentric vote, but several votes of the same character will not drive a thoroughly good Rose out of the forty-eight or place a worthless variety within the charmed circle.

If "WYLD SAVAGE" really wishes to save the Rose election from being "a mockery, delusion, and snare," let him use his influence—not slight, I believe—in urging his brother enthusiasts in the trade and amongst amateurs to vote. Our friend is somewhat inconsistent; he poured the vials of his wrath on the election of 1876, which was the result of "household suffrage." Then we established a franchise, a very fair one I still think, and again he is not satisfied—he would have only those at the National, Alexandra, &c., who appeared as prizetakers; but it does not seem to occur

to him how faulty this may prove, for a man may devote himself say to forty varieties alone, and figure successfully at the National in the twelve or six varieties. This has occurred this very year, and the gentleman declined to give more than twenty-four votes.

In last year's election I ventured to give my idea on an exhibition Rose and its qualities, a valued discussion followed in these columns. I would like to start another subject in connection with exhibiting Roses: What is the best time to cut Roses for exhibition? And again, At what stage should it be cut from the plant to insure its growth in every way after the cutting? Few of us can have helped remarking that one Rose will grow, improve in size, colour, and exhibition qualities for twenty-four or thirty hours after cutting; whilst others, apparently cut under similar circumstances, do not improve at all. Why is this? The conditions of the parent and the atmosphere have, I fancy, some influence on the cut bloom, as well as the time at which the separation takes place and the conditions under which it is kept. I recollect a correspondent, I think it was Mr. Curtis, suggesting that the damp moss used for covering the stands had an injurious effect on the cut blooms and caused their colours to fade. This would be a reason for trying some other material, and the green velvet may, after all, prove the best; but if this be correct, distance is a severe handicapping which only those with very large numbers to cut from can meet successfully, and it would seem also to point to the conclusion that those coming from a distance should not moss their reserve box of blooms.

Whilst penning these thoughts a postcard from "A. C." threw out the suggestion as to what Roses were the most lasting and bore the brunt of travelling the best. Perhaps another year may induce many to give their opinions on this subject.

The electors are, as before, either frequent prizetakers in district shows or prizetakers at the National, Alexandra, or larger meetings. One list has not been used, no name being attached to it, but the list itself will appear. Whatever may be the opinion as to the merits of those voting in the forty-eight varieties, there can be no question that the electors voting in the seventy-two varieties are all growers and exhibitors whose opinions must carry weight. They are all well-known names, and this election must set at rest for a year or two at least the best varieties of our national flower.

Writing before the summing-up of the figures, I still venture to hazard the opinion that the seventy-two will not greatly differ from the general poll except in the position of the Roses, but that the first forty-eight Roses in each poll will nearly agree. I may here say that Mr. Cranston's list is used only in the seventy-two varieties, I having promised this; but I feel certain that all Rose-growers will feel grateful to him that, whilst disbelieving the value of these elections, he has yet given us the benefit of his opinion and yielded to the persuasion of friends to the election.

The columns run thus:—First, the number denoting the position of each Rose on the poll, determined thus:—first by number of votes altogether; these being equal, by greater number of votes in first twelve; if still equal by greater number of votes in the second twelve; if still equal they are

bracketed together. Then the second column gives the name of the Rose, followed by the letters indicating the character of the Rose. Then follow the date of its introduction and the raiser's name. Some blanks may still be found here, but the columns are gradually becoming complete. Then follow the amateur votes, A B C representing respectively the votes given in first and second twelve and the next twenty-four. Then the total of amateur votes. Then the votes of nurserymen. The total and the grand total.

Alongside of this general election of forty-eight varieties I have tabulated the results of the seventy-two varieties as suggested by Mr. Curtis. It is in this election we have Mr. Cranston's list, and besides him we have the following nine nurserymen:—Messrs. G. Paul & Son, Keynes & Co., Curtis,

John Durbin, Davison, Piper, Cant, Turner, and G. Prince. There can be, I imagine, no question as to the value of these opinions. The amateurs, four in number, are scarcely inferior, comprising the Revs. C. P. Peach, Pochin, and Bulmer; and "Hercules." This table requires a word of explanation. The first column denotes the position of the Rose in the seventy-two election, the next column the position of the same Rose in the forty-eight election, so that it is easy to see at a glance the varieties of opinion; then the name of the Rose; then follow four columns containing the first, second, third, and fourth-class votes, according as these are in the first or second twelve, the next twenty-four, or the second twenty-four; then the total votes. I hope this makes the table clear, which I now present to your readers.

FORTY-EIGHT VARIETIES.										SEVENTY-TWO VARIETIES.												
No.	Name of Rose.	Character.	Age.	Raiser's Name.	Amateurs.				Total.	Nurserymen.				Total.	Grand Total.	No.	No. in var.	VARIETIES.				Total.

In the forty-eight varieties 183 Roses have been named by forty-one electors, and in the seventy-two varieties 182 Roses by fourteen electors. Untabulated in the forty-eight varieties three other Roses also muster seven votes—viz., Princess Beatrice, Général Jacqueminot, and the Lælia-Peyronny; eight obtain six votes; twelve are mentioned five times, and here probably are to be found a few Roses that will hereafter take a higher position—to wit, Madame Prosper Langier, La Rosière, and Mrs. Baker. Among the eight obtaining four votes Emily Laxton is found and Duc de Montpensier, one of these being a first-class vote. Nine Roses have but three votes, twenty-one are only named twice, whilst no fewer than fifty varieties have only a solitary vote. It may interest some to know how these fifty solitary votes are divided. These are probably the votes that greatly alter the position of the Roses by taking away a vote that would be given to some already in the list. Fourteen electors have named one, five have named two; three electors nominate three, one names four, and two electors have no less than six. As regards the seventy-two varieties beyond those tabulated nine other Roses were voted for five times, twelve obtained four votes, ten were named thrice, twenty-four could only muster two votes, and out of fourteen electors no less than fifty-six Roses had but a solitary vote. The two lists side by side will make comparisons between them easy; for instance, some of the Roses hold the same position in each list—Marie Baumann, Mons. E. Y. Teas, Marguerite Brassac. Others are widely different; take for example Horace Vernet, which rises from No. 25 in the general to No. 11 in the 72, Beauty of Waltham from 46 to 31, Elie Morel from 70 to 45, this last being the most marked. As instances of the opposite Prince Camille de Rohan sinks from 41 to 62, Duke of Wellington from 29 to 47, and Comtesse d'Oxford from 15 to 32. Yet with these exceptional cases, was I not right in hazarding the prophecy that the two lists would not greatly differ? They are the same with the exception of six Roses! Such a result does not, to my thinking, prove that the forty-one electors make up an opinion which in this case can be considered "a mockery, delusion, and snare." On the contrary, it plainly says that tried by two different tests we have for the present arrived at a fair solution of the best seventy-two varieties of exhibition Roses, and that any novice taking these seventy-two may hope that with the skill, science, soil, and climate necessary for success he may, selecting these, be moderately certain that his Roses, judged by exhibition standard will not disgrace him, at least in the selection; on the contrary, if beaten in the struggle he may rest assured that it will not be chiefly by Roses outside of the charmed circle.

Again I conclude the first portion of the election by warmly thanking the electors for their lists, without which the election would be null and void. I thank them for myself, but I thank them still more cordially for readers of "our Journal" who value the list and anxiously await its appearance. I also desire to thank many of the electors, to whom I am absolutely unknown, for the kind expressions of gratitude towards myself. I must again repeat that the correspondence connected with the election is great and occupies considerable time, and I therefore am unable to reply to these letters, but beg all my kind helpers to accept my thanks in this form. Of their kind opinion I am by no means ungrateful. Gratitude I have, time I lack.—JOSEPH HINTON, *Warminster*.

P.S.—Perhaps this portion is scarcely complete without the names of the voters. They are as follows:—Amateurs: Miss Penrice; Revs. C. P. Peach, J. B. M. Camm, Bulmer, Pochin, Cheales, and Tomlinson; Messrs. W. Palfrey, Mayo, Beachey, R. G. Baker, J. Smith, E. R. Whitwell, T. B. Haywood, John Taylor, J. Graveley, James Brown, J. L. Curtis, Soames, G. Baker, A. J. Waterlow, Robert Craig, gardener to General the Hon. A. Upsten; Capt. Christy, Hand, and Hinton. Nurserymen: Messrs. Balchin, Cant, Curtis, Dickson, Davison, Durbin, Frettingham, Keynes & Co., H. Merryweather, H. May, Mitchell, G. Paul & Son, G. Prince, Piper, Rumsey, and Turner.—J. H.

PANSIES.—Vick's "Illustrated Magazine" contains the following sensible remarks on Pansies:—"Many persons seem to forget that Pansies are imperfect perennials, and expect them to go on blooming year after year like a *Pæony* or a blue *Flag*. It is true they will live for several years, but they will not give large fine blossoms after the plants become old. The seed must be from selected plants and kept pure, or the flowers soon 'run out,' as the common saying is—that is, they become small and common-looking. So whatever else you save your-

self or get from your neighbours never trust any *Pansy* seed but that from a reliable florist. But everything does not depend upon the seed, for it is possible to grow very poor flowers from the best seed by bad treatment; but the best treatment will not produce fine flowers from poor seed."

NOTES ON FRUIT—ROOT-PRUNING AT ASHWELL RECTORY.

YOU published last year a few observations of mine on the culture of Peaches and Nectarines in orchard houses. I spoke then of the very great importance of preventing, or failing that, of stopping as soon as possible the ravages of insects, and also by means of cheap lamp stoves of providing just enough heat during the blossoming period to exclude the frost. It would be superfluous for me to expatiate now upon the necessity of ripened wood for insuring next year's crop, but I may mention that it is my practice to shorten shoots as much as is consistent with prudence as soon as the fruit is gathered, so as to admit as much air and light as possible upon what will be fruit-bearing wood next year.

With regard to root-pruning, it may be interesting to some of your readers for me to state that last November, in order to check a too luxuriant growth, I determined to replant in fresh soil all my cordon trees along a wall about 130 feet in length. Some of these trees were triple, some double, and some single cordons, of which I prefer the last. It seemed not only an herculean toil but a rather hazardous experiment to dig up trees some of which were nearly twenty years of age, but as these "old uns" had gross shoots I made up my mind, whether kill or cure, it should be done. I began by excavating a trench at one end of the border, undermining and carefully lifting each tree in turn, cutting-in its roots, and then immediately transplanting it in some fresh soil—the top spit of a meadow. And here I may remark, that with the trees planted in the border I alternate cordon trees in large pots; and this I find to be a good plan, as giving freer scope to the roots. The result has been most satisfactory. I had some misgivings I must confess. I made up my mind for a short crop the next year, but I expected that in the long run this heroic treatment would yield good results. It turns out, however, that my fears were perfectly groundless. My trees were full of blossom, nearly every blossom set (requiring some trouble in thinning), and fewer fruits than usual fell during the summer immaturity. In fact, I have had a magnificent crop, not only amply providing for my own table, but also affording me the pleasurable opportunity of making acceptable presents of fruit to my friends and neighbours. Dr. Johnson is said to have asked whether anybody ever yet had as much wall fruit as he desired. A lady who happened to be a guest of mine at the end of June told me that she had never had a sufficiency before, but that in my house she had enough and to spare. She came in for the enjoyment of that most excellent Peach the Early Louise, which I can strongly recommend. It is a clingstone, and so does not fall when ripe as so many of the early varieties do, and its flavour is exquisite.

During a pleasant ramble in my short holidays I have had opportunities of comparing notes with brother amateurs, and, considering that the present was said to be a bad season I was surprised at the abundance I witnessed. In the garden of Borden Vicarage I saw wonderful produce of Apples, Pears, and Plums; but alas! the fine Peach trees with a too plentiful crop upon them were ruined by the attacks of red spider. This part of Kent may well be called the garden of England. My next visit was to Horsham in Sussex, and there, both in the orchard house at the vicarage and in the extensive Peach houses of S. Lucas, Esq. (well worthy of a visit), I saw splendid specimens of fruit, such as bore testimony not only to the richness of the soil, but also to the care and skill of the gardeners in charge. I remarked some particularly fine Peaches on the Dymont Peach, also some grand Nectarines on the Victoria, which I am surprised to find is not included in the list of Nectarines recommended by "A KITCHEN GARDENER" in your issue of the 12th inst. I can also speak in laudatory terms of the samples of Peaches I saw and tasted in the orchard house of the vicar of Croydon, Surrey, who trains the branches of one or two trees beneath the glass of his house with remunerative results. His Grapes, his Plums, his Strawberry plants, his Roses, his Gladioli, in fact all that he takes pains to cultivate, have before this been deservedly commended in your Journal in a letter from "D., Deal." Of outdoor Peaches and Nectarines those that pleased me most were those

I saw on the wall of John Fletcher, Esq., of Sunbury, and all the trees in his garden reminded me of "Hesperian fables, true, if true here only," and I felt some perplexity as to whether the palm should be adjudged to the soil of Borden or of Sunbury as more eligible for fruit trees. I must not omit to mention the very fine crops of Peaches and Nectarines both under glass and on the open wall at Heywood near Maidenhead, the seat of Beaumont Hankey, Esq., whose gardener, like Oliver's in "As You Like It," is one of the antique world, who sweat for duty, not for meed. The old school is after all a very good school, whether of wines or gardeners, not only as regards satisfactory results, but also of devotion to their employers' interests.—H. W. HODGSON.

CLIMBING ROSES FOR CONSERVATORY.

A READER, "*VERAX, Manchester*," requests information as to the best six climbing Roses for covering a conservatory roof, the varieties to be of varied colours, and sorts that will produce large quantities of flowers for sale.

This I consider a question of considerable importance, not only to market flower growers but flower growers generally. In the first place there is no style in which Roses can be grown to be seen to greater advantage than when climbing up walls, pillars, and roofs; and secondly, they produce far more blooms when so grown than by any other mode of culture. A number of good climbing Roses constitute one of the greatest treasures any person who grows flowers can possess, and for all kinds of decoration no flowers are more valuable.

"*VERAX*" intends planting *Maréchal Niel* and *Gloire de Dijon*, as two of the six which are wanted. No better could be selected, and of the two I give preference to the *Gloire*. It must be admitted it will not bear the slightest comparison with *Maréchal Niel* when this Rose is in full bloom, but for producing an all-the-year-round supply of fine fragrant blooms I consider the *Gloire* unsurpassed. With private growers two of the *Gloire* should be planted for every one of the *Maréchal*, but for market purposes I think this arrangement might be slightly altered. As a rule Rose blooms will only pay in the market from November until May as grown under glass, and there is no time they pay better than during February, March, and April. This is just the time when *Maréchal Niel* can be had in profusion and in its unequalled beauty. A valuable quality possessed by this grand Rose is that it will grow and bloom freely and fine on the back wall of a lean-to house, even when shaded by Vines or Peaches. In this way it might be grown with much more profit than it often is, as there are many empty walls about both market and other gardens which might be filled with it. *Gloire de Dijon* does not succeed so well on a partially shaded back wall, and it is always more liable to become infested with green fly than any other Rose which we have grown.

In addition to the two named I would advise "*VERAX*" to plant *Cheshunt Hybrid* (cherry carmine), *Niphetos* (beautiful white), *Belle Lyonnaise* (deep canary yellow tinted with salmon), *Céline Forestier* (very fragrant, fine bright yellow), and if a Rose is wanted to produce exquisite buds *Madame Falcot*, which is a very deep yellow or kind of bronze, and a continuous and exceedingly free bloomer.

In the culture of these Roses it is not advisable to restrict them in growth too much; in fact to do them justice and allow them to produce large quantities of bloom, closely training them to rafters in a conservatory is not the surest way of securing the best results, and the Roses should not be made a secondary consideration to the plants that may be underneath them. No other flowers will pay either public or private growers better than Roses, and whatever else may be neglected they should have the treatment they require. In training them they need much more room to extend their branches. They will flower fairly well when tied to pillars or rafters for decorating the house in which they are growing, but to secure thousands of blooms for sale the best way is to cover the roof with a light wire trelliswork, the same as is done for Vines, and train the shoots of the Roses all over it. Many kinds of plants, such as Ferns, Camellias, and newly potted plants generally, will grow very well under this trellis, for Roses do not shade so much as Vines. Whichever way the Roses are trained the shoots must not be crowded, at the same time no more pruning should be done to those I have named than will just prevent them from doing this. Cutting out a few of the weak shoots and any strong old branch about this time of the year is all the pruning ours receive. Plenty of rich material

is requisite for them to grow in, and a free extension of the branches just suits *Maréchal Niel*: indeed this applies to all climbing Roses with which I am acquainted. Strong loam well enriched with cow dung, and plenty of good liquid manure when growing and flowering, suit them admirably. Plants in pots may be planted now or at any other time during the year; others had better be left until they are at rest before they are dug up and replanted.—M. M.

AMERICAN MOTHER APPLE.

HAVING seen the above Apple recommended I purchased trees of it, and am now disappointed with their produce. The fruit is small, yellow, and by no means good. Can I have the true variety? I send you a specimen.—L. L. D., *Oxon*.

[You have not the true variety. Twenty years ago we described the American Mother as one of the best of autumn Apples. It originated at Bolton, Massachusetts, and was introduced to this country by Mr. Rivers of Sawbridgeworth. We then advised that care must be taken not to confound this variety with those that bear the same name in this country.]

Fig. 37.—American Mother Apple.

There is a "Mother Apple" grown in some of our cider districts, a little ovate yellow fruit, having the unpalatable flavour of a Bittersweet; and then there is the *Oslin*, which in some parts of Scotland is called "Mother Apple." Both of these are perfectly distinct from that which is now under consideration, and which was therefore called the "American" Mother Apple.

Fruit above medium size, conical, uneven, and undulating on its surface, and generally higher on one side of the crown than the other. Skin golden yellow, covered with patches and streaks of crimson on the side next the sun, and strewn with russet dots. Eye small, closed and tapering, set in an open basin. Stalk half an inch long, very slender, inserted in a deep cavity. Flesh yellowish white, remarkably tender, crisp, and breaking, very juicy, sweet, and with a balsamic aroma.

The outline and description will enable the true variety to be recognised.]

POTATO DISEASE AND ITS PREVENTION.

THE following suggestions for checking the Potato disease have been addressed by Mr. G. H. With, F.R.A.S., to the tenants of the Hereford Society for Aiding the Industrious:—

The yearly destruction of our Potato crop, and the great loss of food which follows, render it absolutely necessary that some plan for checking and, if possible, rooting out the disease, should be tried without delay. After giving a good deal of attention to the subject I offer these suggestions, with the full belief that, if they are carefully followed, results will be

obtained which will far more than repay the trouble. The Potato disease is owing to the destructive action of two kinds of mildew, and it starts afresh every year from seeds, or spores as they are called, which have rested during the previous autumn and winter either in the ground, or in the Potato tubers, or in the manure heap.

1, Burn the haulm and all waste Potatoes, parings, &c., not intended for the animals as soon as possible after the crop has been raised. Unless this is done the decaying haulm and waste Potatoes may fill the ground with the seeds of the destroying mildews.

2, Do not throw the haulm and waste Potatoes upon the manure heap, because the mildew seeds will gain in strength by resting in the manure, and this manure will help to spread the Potato disease next season.

3, Boil for a long time all diseased and even apparently sound Potatoes before you feed animals with them. It is highly probable that the seeds of the Potato mildews gain strength by passing through the stomach of an animal—the pig, for instance. The manure of animals fed on raw diseased Potatoes and Potato parings may, for the above reason, become a powerful means of spreading the Potato disease.

4, Do not grow Potatoes on the same piece of land two years in succession. Any mildew seeds which may rest in the ground from the last year's Potato crop will begin to grow about the beginning or middle of May; but they will quickly perish if they cannot find Potato plants at hand to nurse them.

5, Be sure the seed Potatoes are quite free from disease when planted. A Potato does not always show the disease on the outside; therefore it will be necessary to cut the sets, in order that the condition of each one may be seen. A few diseased plants will serve to infect acres of Potatoes in a wet warm season.

6, Use chemical manures in preference to any others for the Potato crop. Ordinary manures may, especially if brought from a distance, contain the mildew seeds.

7, A Potato crop may generally be saved by pulling up the haulm throughout the whole crop as completely as possible directly the disease spots appear on the leaves of any one of the plants. Of course the tubers will not grow any larger after the leaves and stalks have been removed. They will, however, ripen in the ground, more or less according to the season, and though they may not be very large they will be fit for food.

8, To ensure success all the Potato growers of a neighbourhood should follow the above plan. One plot of diseased Potatoes may furnish seeds enough in July to destroy the surrounding Potato crops.

CRYSTAL PALACE—FRUIT AND POTATO SHOWS.

SEPTEMBER 24TH AND 25TH.

ONLY a very large building such as the Crystal Palace could have accommodated at the same time two such Shows as those under notice—the twenty-third annual Exhibition of fruit promoted by the Crystal Palace Company, and the fourth International Potato Exhibition instituted by a committee of gentlemen earnest in improving the Potato both as to culture and varieties. The first-named Show was under the management of Mr. Thomson, the Crystal Palace Company's skilled garden manager; and the Potato Exhibition was arranged under the experienced superintendence of Mr. J. A. McKenzie.

THE FRUIT AND VEGETABLE SHOW.

Fruit was exhibited on a larger scale than usual at the Palace. Pines were not numerous, and as a rule were not quite equal to those exhibited during some former years, yet most of those that obtained the prizes were very good. Grapes were staged in great numbers, and many of them were remarkably fine, notably the Muscats, Gros Colman, and three bunches of Golden Queen. For these the Show will be remembered. It will also be remembered as the occasion of a bold precedent, inasmuch as by far the best collection of Grapes exhibited was disqualified because Muscat of Alexandria and Bowood Muscat were staged as distinct kinds. The Judges—Messrs. Barron, Douglas, and Baker—officially declared them identical, and hence the exhibitors (Messrs. Lane and Son, Great Berkhamstead) were placed out of competition; but their collection was highly commended for its great excellence. Mr. Tyler, gardener to R. Gosling, Esq., Haslebury, was also disqualified in the class for five distinct kinds for the same reason as Messrs. Lane, otherwise he would probably have secured the premier position. This collection, too, was highly commended. Apples and Pears were excellent; Peaches fine, but not highly coloured; Nectarines few, Plums small, Melons numerous, and vegetables splendid. Referring to the classes, first in order come the

two dishes of Grapes, two Pine Apples, and two Melons were admissible, but not more than one dish of any other variety. Four collections were staged, Mr. Coleman, gardener to Earl Somers, Eastnor Castle, securing first honours with a very fine collection, including a good Queen and fine Smooth Cayenne Pine but too heavily crowned; fine Muscat and good Black Hamburg Grapes; two capital Melons, Eastnor Castle and Read's Scarlet-flesh; good Barrington Peaches, Pine Apple Nectarines, Williams' Bon Chrétien Pears, Morello Cherries, Brown Turkey Figs, and rather small Golden Drop Plums. Mr. G. Sage, gardener to Earl Brownlow, Ashridge, was an excellent second, his Queen Pine being especially fine, Black Hamburg Grapes remarkably well finished, and other fruits good. Mr. Goodacre, The Gardens, Elvaston Castle, had the third place; his Muscat Grapes were full and well finished, and Lady Downe's were excellent. The collection also included a dish of Garibaldi Strawberries.

In the class for six dishes of fruit, distinct kinds, Pines excluded, there were sixteen competitors, but five of them were disqualified for having staged two varieties of Grapes. Mr. Haycock, gardener to R. Leigh, Esq., Barham Court, Maidstone, had the premier award. He staged admirably finished Black Alicante Grapes, a magnificent Golden Gem Melon, splendid Louise Bonne of Jersey Pears, a good dish of Lord Palmerston Peach, highly coloured Pine Apple Nectarines, and Golden Drop Plums. Mr. C. J. Goldsmith, gardener to H. T. Lambert, Esq., Sandhills, Bletchingley, secured the second prize with a remarkably good collection. Mr. H. Folkes, gardener to T. F. Halsey, Esq., Gaddesden Park, Hemel Hempstead, was placed third for highly creditable produce. Some inferior collections were exhibited in this class, but the majority were very good, and it was not easy to make the awards. The decisions, however, were unquestionably correct.

The next class of six dishes, distinct kinds, exclusive of Pines and Grapes, also gave the Judges much trouble. Ten collections were staged, but some exhibitors were disqualified for placing more than the stipulated number of fruits in a dish. The prizes were awarded first to Mr. Haycock, second to Mr. Chisholm, gardener to R. C. Taylor, Esq., Boughton Place, Maidstone, and third to Mr. Wildsmith, gardener to Viscount Eversley, Heckfield. All the collections were very good, Mr. Haycock's consisting of a Melon, Brockworth Park Pears, Lord Palmerston Peaches, Pine Apple Nectarines, Kerry Pippin Apples, and Pond's Seedling Plums, all splendid. Mr. Ross, gardener to C. Eyre, Esq., Welford Park, Newbury, would have had the second prize in this class had he exhibited in conformity with the conditions at the head of the schedule, where it is stated that a dish of Figs must consist of six fruits.

GRAPES.—In the class for ten kinds, two bunches of each, there were five competitors. Messrs. Lane & Sons having been disqualified for the reason above stated, first honours fell to Mr. Wildsmith. His Black Hamburgs were small, but all the rest good—namely, Mrs. Pince (quite ripe), Buckland Sweetwater, Alicante, Gros Guillaume, Trebbiano, Gros Colman (well coloured), Venn's Muscat (full and good), Muscat of Alexandria, and Lady Downe's, the bunches ranging from 2 to 3 lbs. Mr. Bannerman, gardener to Lord Bagot, Rugeley, was a rather close second; and Mr. Goodacre third with small but well-ripened bunches. Messrs. Peed & Son exhibited in this class, staging Tottenham Muscat and Muscat of Alexandria, which being ruled identical the collection was ineligible for a prize.

Six collections were staged in the class for two bunches each of five kinds. Mr. Tyler having been disqualified for including the two Muscats referred to, first honours fell to Mr. Sage, Ashridge, who staged excellent Muscats, Lady Downe's not quite ripe, splendidly coloured Alicantes, Trebbianos, and Black Hamburgs. Mr. Woodbridge, The Gardens, Syon House, was placed second with Madresfield Court, full and compact; good Muscats, a cluster of Alicantes, Golden Champion, small bunch, fine berries, and clear; and good Lady Downe's. Mr. Mowbray, gardener to the Earl of Leven and Melville, Fulmer Gardens, Slough, secured third honours with a smart and clean collection—Muscats full and regular; Lady Downe's, not quite ripe; Alicante, good; Black Hamburg, excellent; and capital examples of Royal Muscadine.

In the class for three bunches of Black Hamburgs sixteen lots were staged. Most of the bunches were small or medium-sized, some not well coloured, and none of superior merit as combining good size with high quality. Mr. Wildsmith was fortunate in securing first honours with bunches not exceeding three-quarters of a pound in weight, but the berries were well finished and of undeniably good quality. Mr. Upjohn, gardener to the Earl of Ellesmere, Worsley Hall, Manchester, was placed second with bunches weighing 2 lbs.; berries, too, of good quality, but one or two of them were small and slightly-rubbed. If Mr. Upjohn had taken out about three small berries he would have won "a canter," as it was he must have felt it hard to have lost. Mr. Goldsmith was third with good-sized bunches, full and regular, but berries rather small. Only a moderate class.

Very different was the class for three bunches of Muscat of Alexandria, in which there were thirteen competitors. Messrs. Lane and Son won the chief position with bunches grand in all points, one of them a veritable model in shape, also in size, regularity

COLLECTIONS OF FRUIT.—In the collection of twelve dishes

and finish of berries. The bunches were about 15 inches long and weighed from 3 to 4 lbs. Mr. Coleman was placed second also with splendid bunches, large, full, clear, and fine, but not perfectly ripe. Mr. Bannister, gardener to H. St. V. Amer, Esq., Cote House, Westbury-on-Trym, Bristol, secured third honours with excellent bunches of about 3 lbs. An extra prize was awarded to Mr. Jarman, gardener, Westwood Lodge, Isle of Thanet, for bunches full, heavy, and altogether fine. A remarkably fine class.

Nine collections were staged in the Madresfield Court class, Mr. Woodbridge securing the first position with medium-sized well-shaped bunches and fine berries, but not fully ripe. Mr. Ward, gardener to T. N. Miller, Esq., Bishop Stortford, had the second place with smaller bunches but better-coloured berries, and Mr. Upjohn was third with handsome bunches, but berries not quite ripe. The three collections were of nearly equal merit, but the rest were far behind. Only a moderately good class.

Gros Colman, of which four collections were staged, was splendid. Mr. Coleman won first honours with moderate-sized bunches, and berries which for size and high finish we have never seen equalled. Messrs. Lane & Son were second with much larger bunches and fine and well-coloured berries—excellent; and Mr. Upjohn was third, also with capital examples of culture. A small but imposing and superior class.

Sixteen competitors entered the arena in the Lady Downe's class. Some of the fruit was not half ripe, some was rubbed, other bunches excellent. Mr. Coleman was first with small bunches, but so smart, clean, and fine in berry that the Judges could not justly have placed them in a different position. Mr. Jordan, gardener to Birket Foster, Esq., The Hill, Witley, Godalming, had the second place with very fine bunches and highly creditable in all points; Mr. Bannerman was a very close third. A very good class.

Buckland Sweetwater was represented by bunches of almost all sorts, from very good down to very bad. Mr. Bungay, gardener to W. Smith, Esq., Hill House, Herne Hill, secured the first position with large but rather loose bunches, but good berries, clear and ripe. Mr. Grough, gardener to E. M. Barrington, Esq., Little Malvern Court, Worcestershire, was placed second with smaller bunches, but berries of capital quality; and Mr. Masters, gardener to F. Day, Esq., Oatlands Park, Weybridge, third with bunches still smaller, but the most perfectly ripened and best-finished berries in the whole class.

The class for any other white Grape than those above mentioned brought out eight competitors. Mr. Atkins, Lockinge Gardens, Wantage, easily won first honours with splendid examples of Golden Queen, the best probably ever exhibited. They averaged about 3 lbs. in weight, were handsome in shape, and the berries were very regular and fine, also fairly clear in colour. Mr. Jordan was second with large and full bunches of Foster's Seedling, but berries rather small; and Mr. Jones, gardener to Lord Calthorpe, Elvetham Park, Winchfield, third with the same variety in excellent condition.

In the corresponding class for any other black kind sixteen growers competed for the prizes. The majority of the exhibits were Alicantes, and this variety was staged in splendid condition by Messrs. Lane & Sons, who secured the chief honours. Mr. Perks, gardener to C. W. Dieseldorf, Esq., Laurie Park Gardens, Sydenham, was second with Gros Guillaume of first-rate quality; and Mr. Goodacre third with Alicante. In this class Mr. Bell, Clive House, Alnwick, exhibited Alnwick Seedling, fine in bunch, berry, and colour, but not nearly ripe; indeed, it was almost sour, and hence it was passed by the Judges. A very good class indeed.

The last class in the schedule was for the heaviest bunch, white or black, and here Mr. Kirk, gardener to Mrs. McKie, Castle Douglas, Kirkcubrightshire, was a long way ahead of his rivals with a bunch of Trebbiano weighing 16 lbs., the berries being remarkably fine, clear, and very regular. It was a fair bunch on a simple peduncle, and a fine example of culture. Mr. C. Tyler, Hassobury, was a good second with Gros Guillaume, weighing 9 lbs. 2 ozs. A fine-shaped bunch, and most of the berries good and well coloured. Mr. Bones, gardener to D. McIntosh, Esq., Havering Park, Romford, had the third position with Black Hamburgh, weighing 7 lbs. 2 ozs., the berries being very fine, but not well coloured. It may be remarked that the winner of the first prize in this class exhibited a collection of five kinds, which at the first glance appeared much the best in the class, but on closer inspection it was clear that they were stale and worn, and decay had set in in the interior of the bunches; hence they were properly passed by the Judges. The notable bunch was a fine example of Duke of Buccleuch. Mr. Kirk has taken good prizes in Scotland this year, and it redounds much to his credit as a cultivator that all the Grapes he has exhibited have been grown in a house 30 feet long.

The show of Grapes was probably the most extensive that has ever been held at the Crystal Palace, the result, no doubt, in a great measure of Mr. Thomson's energy, tact, and courtesy. The Exhibition was enhanced in effect by several excellent examples of Vines in pots from the nurseries of Messrs. Lane & Sons, which were placed at intervals along the central table instead of, as is often the case, being huddled together at one end of a show.

PINES.—The show of these was not extensive. Some of the fruits were fine, but several of them had disproportionately large crowns. In the class for one Pine Apple, Queen, there were only four exhibitors. The first prize was awarded to Mr. Sage, Ashridge Gardens, Berkhamstead. Mr. W. Coleman, Eastnor Castle, was placed second; and Mr. J. Akehurst, gardener to S. Copestake, Esq., Highgate Road, third, all exhibiting very clean and evenly-grown fruit. For one fruit of Smooth Cayenne Mr. Charles Ross, gardener to C. Eyre, Esq., Welford Park, Newbury, was placed first; Mr. W. G. Pragnell, gardener to G. D. W. Digby, Esq., Sherborne Castle, Dorset, second; and Mr. D. Wilson, gardener to Earl Fortescue, Castle Hill, North Devon, third, with very large and handsome fruit. In the class for one Pine Apple, any other kind, there were only three exhibitors, and the prizes were awarded to Mr. G. T. Miles, gardener to Lord Carington, Wycombe Abbey, Bucks; Mr. J. Akehurst, and Mr. J. Muir, gardener to C. R. M. Talbot, Esq., M.F., Taibach, South Wales, in the order named. The fruit exhibited by Mr. Miles was a very handsome Charlotte Rothschild Pine weighing 7 lbs. The others were smaller, Mr. Muir staging Prince Albert.

PEACHES AND NECTARINES.—Thirty-five collections were staged in the class for a dish of Peaches, six fruits of each, Mr. J. Coombs, Sheen House, Mortlake, Surrey, winning first honours with very large, highly-coloured fruit of Lord Palmerston. Mr. J. Smith, Wotton Gardens, near Aylesbury, Bucks, was placed second with Late Admirable; and Mr. W. Coleman, Eastnor Castle, Ledbury, third with Barrington. An extra prize was awarded to Mr. C. J. Goldsmith, gardener to H. Lawley, Esq., Sandhills, Bletchingley, Surrey, for very large fruit of Princess of Wales, but somewhat damaged in transit. Peaches as a rule were large, but somewhat deficient in colour. Nectarines were not so numerous exhibited, there only being about a dozen dishes. The best was Pine Apple from Mr. Coleman; the second prize was awarded to Mr. J. Neighbour, gardener to G. Wythes, Esq., Bickley Park, Kent, for the same variety; and the third to Mr. G. Wortley, gardener to Admiral Hon. P. Cary, South Norwood Hill, for Prince of Wales.

MELONS.—Sixty-four Melons were staged, amongst which there were some very fine fruit for the season, but they were not remarkable for high flavour. Mr. Haycock was awarded the first prize, Mr. Charles Osman, gardener, South Metropolitan District Schools, Sutton, the second, and Mr. Charles Tyler, gardener to R. Gosling, Esq., Hassobury, Bishop Stortford, the third for green-flesh; and for scarlet-flesh the prizes fell to Mr. Joseph Atkins, Lockinge Gardens, Wantage; Mr. Woodbridge, Syon Gardens, Brentford; and Mr. J. C. Goldsmith, in the order of their names. Only one dish of Figs was staged, and that came from Mr. Sage, who was awarded the first prize.

PLUMS.—These were generally small. In the class for three dishes, distinct, there were twenty-four competitors, Mr. Sage winning the first prize with Coe's Golden Drop, Jefferson, and White Magnum Bonum. Mr. John Wells, gardener to R. Ravenhill, Esq., Fernhill, Windsor Forest, was placed second, his notable dish being Denyer's Victoria, very large. Mr. John Staple, Chipstead Place, Sevenoaks, was third. Extra prizes were awarded to Mr. Coleman and Mr. Fry, gardener to L. J. Baker, Esq., Eastcote, Pinner.

APPLES.—Ninety dishes of dessert Apples were staged, the whole of which were of very superior quality, remarkably high coloured, and uniform in size. To Mr. E. Bowles, gardener to W. Skinner, Esq., Beresford House, Maidstone, the first prize fell for Ribston Pippin, Cox's Orange Pippin, and a very handsome dish named Duchess of Gloucester. Mr. W. Goldsmith secured the second prize, and Mr. C. Haycock the third. Kitchen Apples.—There were forty-five collections, representing over eight hundred fruits—a sight worth seeing, the majority being extraordinarily fine. The first, second, and third prizes fell respectively to Mr. E. Bowles for Winter Hawthornden, Warner's King, and Stone's Seedling; Mr. James Pluck, New Street, Jersey, for Grosse Menagere, Reine d'Angleterre, and Alfriston; and Mr. P. V. Pluck, Union Street, Jersey, for Poll's Seedling, Alfriston, and Mère de Ménage. Extra prizes were awarded to Mr. Haycock and Mr. Murrell.

PEARS.—In the class for dessert Pears there were twenty-six competitors. Mr. Haycock was awarded the first prize for a very beautiful collection comprising Louise Bonne of Jersey, Fondante de Cœur, and Doyenné Boussoch. Mr. G. Gouch, gardener to C. M. Barrington, Esq., Little Malvern Court, Worcester, was awarded the second prize, and Mr. James Dean, Godstone, Surrey, the third; Mr. J. Pluck received an extra prize, all exhibiting admirable collections. For kitchen Pears the first and second prizes went to Jersey, Messrs. J. and P. V. Pluck receiving the awards for enormous-sized fruit; Mr. W. Fanning, The Convent, Rochester, being placed third.

VEGETABLES.—In the class for sixteen distinct varieties of vegetables Mr. W. Pragnell surpassed all other competitors, of which there were nine, exhibiting a splendid collection comprising Veitch's Autumn Giant Cauliflower, The Student Parsnips, Schoolmaster Potatoes, Brussels Sprouts, Ne Plus Ultra Peas, Scarlet Runner Beans, Tender-and-True Cucumbers, Improved White

Spanish Onions, Jackson's Mammoth Tomatoes, Globe Artichokes, Major Clarke's Celery, Carentan Lettuce, James's Intermediate Carrots, Long White Vegetable Marrows, Early Snowball Turnips, and Exhibition Beet: this collection was beautifully set up. Mr. C. Chaff, gardener to C. H. Goschen, Esq., Ballards, Addington, was placed second with a very excellent collection; and Mr. J. H. Goodacre, gardener to the Earl of Harrington, Elvaston Castle, Derby, third, who also had a very good display. Mr. R. Philips, gardener to Captain Jackson, The Deodars, Meopham, Kent, received an extra prize. In the class for eight distinct varieties sixteen collections were staged. Mr. John Baker, Broad Street, Brompton, Oxfordshire, was placed first; Mr. Charles Ross and Mr. W. Iggulden, gardener to R. B. W. Baker, Esq., Orsett Hall, Romford, Essex, equal second; and Mr. John Day, gardener to A. Seymour, Esq., Norton Hall, Daventry, third, all exhibiting well. Collections of four varieties came from Mr. C. Howard, Bridge, Canterbury. Mr. G. Woodham, gardener to W. Wright, Esq., North Dulwich, and Mr. John Sutton, Queenwood, Beddington, Croydon, who were placed first, second, and third respectively.

MISCELLANEOUS.—Several extensive and valuable collections of fruit, flowers, and vegetables were exhibited in this class, and extra prizes were awarded to Messrs. John Laing & Co., Stanstead Park, Forest Hill, for cut flowers of Tuberous Begonias in splendid varieties; to Mr. Robert Brown, gardener to F. T. Barry, Esq., St. Leonard's Hill, Windsor, for Asters; and Mr. Morgan, gardener to Major Scott, Reigate, for Asters; to Messrs. Rawlings Brothers, Romford, Essex, for a collection of Dahlias; to Mr. Walker for Onions the same as exhibited last week at South Kensington; to Mr. Cracknell, Dickwood House, Sydenham Hill, for a collection of Tomatoes, &c.; to Mr. L. A. Killick, Mount Pleasant, Langley, Maidstone, for a fine collection of Apples of about one hundred varieties; to Messrs. W. Paul & Son for an extensive collection of both Pears and Apples, numbering about two hundred dishes of the latter and sixty of the former; to Messrs. Rivers & Sons of Sawbridgeworth for splendid dishes of Pears, Apples, and Peaches; and to Mr. Foulle, gardener to Sir H. Midway, Bart., for a collection of Apples; to Messrs. Paul & Son, the Old Nurseries, Cheshunt, for a collection of 160 varieties of Apples and a large number of Pears; to Messrs. W. Paul & Son for ten beautiful boxes of Roses, which were particularly fine for so late in the season; a box of Safrano, Niphetos, and several other Teas were very pretty indeed. To Messrs. G. Paul & Son for a large collection of Roses, amongst which were a box of Capitaine Christy very beautiful; and an extra first prize to Mr. Muir, gardener to C. R. M. Talbot, Esq., for a remarkable collection of fruits of the Orange tribe in twelve varieties, which had been ripened in the open air, and which attracted considerable attention.

Mr. Wilson, gardener to Earl Fortescue, exhibited a triple Pine Apple, each fruit weighing from 2 to 3 lbs.; and Mr. Thomson exhibited male and female cones of *Encephalartos villosus*, the former being nearly 2 feet in length and the latter 9 inches, which had been grown in the Crystal Palace.

THE POTATO SHOW.

The Exhibition was a very extensive one, and the Potatoes were generally of very high quality. There was also a welcome absence of polishing, which in some past shows imparted to the tubers such an unnatural appearance; still in one or two collections there was a suspicion that the Potatoes had been washed in something more than pure water, although perhaps not in buttermilk. In the great class for twenty-four varieties Peter McKinlay, Esq., Beckenham, won the premier prize with perhaps the finest collection that has ever been staged. The following are the varieties:—Grampian, Snowflake, Trophy, Schoolmaster, Lady Webster, Porter's Excelsior, Blanchard, Woodstock Kidney, Ash-top Fluke, Shelburne, Beauty of Hebron, Early King, Late Rose, Rector of Woodstock, Beckenham Beauty, International, Red Emperor, New Cambridge Kidney, Extra Early Vermont, Onwards, Edgcott Seedling, King of Potatoes, Superior, and Breadfruit. Second Mr. J. Pink, Lees Court, Faversham; third Mr. W. Finlay, Banbury, Oxon; fourth Mr. G. Bagerley, Lysterston Lodge, Newark; fifth Mr. Ellington.

In Class B, for eighteen varieties, twenty-four collections were staged for the prizes offered by Messrs. Sutton & Sons. Mr. F. Cresswell, gardener to Lord Gwydyr, was placed first with King, Manhattan, Coldstream, Red-skin Flourball, Burntink Seedling, Lady Webster, Bresee's Peerless, Carter's Breadfruit, Magnum Bonum, Snowflake, International, Vermont Beauty, Schoolmaster, Beauty of Hebron, Superior, Norfolk Giant, Covent Garden Perfection, Early Goodrich. Mr. James Pink was second; Mr. G. Bagerley third; Mr. J. Belliss, gardener to Major Thoyts, Reading, fourth; and Mr. J. Wildsmith, Heckfield, fifth. Great surprise was expressed by many exhibitors that the first prize in this class should have been awarded to specimens that were altogether too large to be placed on any gentleman's table. In Class C, for twelve varieties, sixteen collections were staged. Mr. W. Finlay received the first prize with Schoolmaster, Scotch Blue, Prince of Wales, Lapstone, Crimson Ashleaf, Red Fluke, Royal Ashleaf, Wonderful, Salmon Kidney, Rector of Woodstock, Mag-

num Bonum, and Red Regent—a splendid collection. Mr. James Pink was second with splendid dishes. Mr. R. Dean, Ealing, third; and Mr. W. Ellington fourth. In Class D, for nine American varieties, twelve collections were staged, the first prize falling to Messrs. Lott & Hart, Faversham, for Trophy, Early Goodrich, Brownell's Beauty, Superior, Bresee's Prolific, and Beauty of Hebron. Mr. James Pink was second, Mr. R. Farquhar, Fyvie, N.B., third, and Mr. Peter McKinlay fourth. In Class E, for six dishes distinct, to include Lye's Favourite, fourteen collections were staged for Messrs. Daniell's prizes. Mr. William Finlay, Oxon, won the first position with Lye's Favourite, Schoolmaster, Scotch Blue, Blanchard, Porter's Excelsior, and Edgcott Seedling, even-sized and polished. Mr. James Miller, Hamstead Park, Newbury, was second, Messrs. Lott & Hart third, and Mr. James Pink fourth. In Class F, for four dishes, two rounds and two kidneys, thirty collections were staged, Mr. William Finlay being placed first with Blanchard, Magnum Bonum, Lapstone, and Scotch Blue. Mr. F. Miller, gardener to J. F. Friend, Esq. Margate, was second, Messrs. Lott & Hart third, and Mr. R. Dean fourth. In Class G, six dishes of new varieties not in commerce, Mr. James Pink secured the first prize with Early King, Triumph, Manhattan, Trophy, Beauty of Kent, and Beauty of Hebron. Mr. P. McKinlay was second, and Messrs. Lott & Hart third. In Class H, for two dishes, round and kidney, thirty-six collections were staged. Mr. C. Howard, Bridge, Canterbury, was first with Schoolmaster and Edgcott Seedling; Mr. C. Ross second, and Mr. R. Dean third.

SINGLE DISHES.—In Class J, for the best dish of any white round Potato, thirty-five collections were staged. Mr. R. Ironside, Ingleston, Inverarie, was first with Early Handsworth; Mr. J. Belliss second with Schoolmaster; and Mr. A. Halliday, Old Meldrum, N.B., third. In Class K, for the best dish of any coloured round Potato, thirty-one collections were staged, Mr. W. Emerson, Cold Ashby, Welford, Rugby, being placed first with Red Emperor; Mr. P. McKinlay second with Blanchard; and Mr. J. Miller, Newbury, third with Red Emperor. In Class M, for the best dish of any coloured kidney variety, twenty-nine collections were staged. Mr. R. Farquhar was first with Purple Ashleaf, Mr. R. Dean second with Garibaldi, and Mr. W. Finlay third with Bountiful. In Class N, for the best dish of International Kidney, twelve collections were staged. Mr. Finlay was first, Mr. C. Ross second, and Mr. G. Bagerley third; all staging splendid dishes. In Class O, for the best dish of Covent Garden Potato, eleven collections were staged. Mr. R. Farquhar was first, Mr. J. N. Belliss second, and Mr. F. Cresswell, gardener to Lord Gwydyr, third. In Class P, for the best dish of any White Ashleaved Kidney, sixteen collections were staged. Mr. G. Bagerley was placed first with Ash-top Fluke, Mr. R. Farquhar second with Old Ashleaf, and Mr. W. Finlay third with the same variety. In Class Q, for the best dish of Grampian, Mr. John Falconer, Kintore, Aberdeen, N.B., was placed first; Mr. James Neighbour, Bickley, Kent, second; and Mr. G. Bagerley third.

The total number of dishes in competition at this great and good Show was 1539. In addition to the above, extensive miscellaneous collections were staged by some of the principal trade growers. Messrs. Sutton & Sons exhibited fifty dishes of all the leading show varieties, including the new Woodstock Kidney, a beautifully shaped rough-skinned variety of great promise; also fine heaps of Magnum Bonum. Rector of Woodstock, Yorkshire Hero, Early Oxford, and Sutton's King of Potatoes were especially fine in this collection. Messrs. Carter & Co. exhibited grand heaps of Improved Magnum Bonum grown at Sandringham, Snowflake, Bresee's Prolific, Schoolmaster, Carter's Excelsior, and other varieties of superior merit; and Messrs. Hooper and Co. staged twenty-two baskets principally of American varieties. The certificates were not awarded when we left the Exhibition, which was altogether a great success. The patrons of the Society, Judges, &c., dined together in the Marble Hall of the Palace after the adjudication of the prizes.

DRESSING CARNATIONS.

DOES not "WYLD SAVAGE" dress the Rose at all? Are the fine flowers he shows the natural growth of the half-starved stunted plants which are grown in his garden? Does he add a leaf or two, sometimes a bud, to his flower? Does he tie the flowers up with a piece of twine or bast, and cut the same just before leaving the stands for the judges to go over? If so, is it not dressing? Dressing the Carnations is legitimate, or at least it would be considered so in any court. I have been a dresser of these flowers during nearly thirty years, and I knew men when I commenced who had been dressers nearly fifty years; this takes up fully three-quarters of a century. If the answer is, "You had nothing to dress then," that is a mistake. We had at that day nearly as fine Carnations as we have now. It is only in Picotees that, thanks to Messrs. Dodwell, Norman, Turner, Simonite, and a few others, we have lately approached perfection. I have in my possession an account of the "flower

shows," as they are called, held in England in 1821. There are particulars of thirty-seven exhibitions of Carnations alone, containing the names of 189 winning varieties of Carnations and fifty-two of Picotees. The flowers were dressed at that date, and hard, too, it used to be then—two tiers of petals and a crown; now the flowers are dressed more naturally.

Having proved the antiquity of dressing let us see its effects as practised now. The Carnations we exhibit are grown generally in pots, and the plants in most cases are disbudded to some two or three buds in order to obtain size of flower. Some growers bloom them on a card, dressing or laying down the petals as they expand. When done this way the dresser can make little, if any, improvement in a flower.

Another advantage of this mode is that it prevents the back petals of a flower from curling under, which when they do in an old flower are almost impossible to be straightened.

Some say to me, "Why grow flowers given to curling?" I should be glad to discard them, only we have nothing as good in other respects to grow in their place, and, what is more, do not expect we shall have for a number of years, good seedlings being produced so rarely.

The calyx needs attending to in some varieties, being so stiff that if the flower is not assisted by slitting down the segments probably it will never expand, but burst out on one side and form what is called a "split pod." Also in the stiff calyces the points of the calyx interfere with the laying-down of the petals, standing up as they do amongst them. In this case the dresser, using a pair of strong steel tweezers, turns round the points of the calyx, which leaves room for the petals to expand and show themselves to advantage.

The Carnation being a sportive flower, its flowers frequently show more colour in the petals on one side than another, and then the dresser assists in distributing the petals.

Originally a single flower containing four petals, now perhaps a score, these have to grow through the calyx, the outer portions of the petals being so much larger than the footstalks enlarge the calyx, so much so that in some situations the petals are all open together, and if dressing is not to be allowed I for one should be unable to exhibit. As to blooming them on a card, that is out of the question, as there is no doubt but that both flower and card would be wrenched off by the wind.

"WYLD SAVAGE" complains that the rabbits are troublesome, eating the plants. The florist has to prevent them so doing. This is very easily effected. A stage 3 feet high to stand the pots on, or a little wire fencing to form a fence around the stage 13 yards by 4, will give ample room for three hundred pots or six hundred plants. After layering and when taken off they have the protection of a frame (which can easily be made rabbit-proof) during the winter months, a two-light frame 6 feet square being sufficiently large to winter that quantity.

If the soil in "WYLD SAVAGE's" garden is so poor as he says, I think he cannot do better than substitute the growth of Carnations for Roses, as they do not require a couple of barrow-loads of soil and manure each as the Rose does. He would find that two loads of good turfy loam with a mixture of decayed dung and leaf soil would be ample to grow four or five hundred pots of Carnations. The soil after being used for Carnations would grow Roses another year. I remember growing a few Roses in pots some twenty years ago. At the end of the season when I had emptied the soil out of my Carnation pots I also emptied out at my liquid manure tub, which contained sheep dung. In this I planted my Roses, and I never remember to have had a finer bloom than I had the spring following.

When I was a young grower the growing of Auriculas, Carnations, &c., used to be mystified, but, thanks to Mr. Dodwell and a few others, there is now no secrecy about it. If a beginner wants to learn to dress flowers he has nothing to do but attend an exhibition, and nearly any florist there will show him.

I would recommend at an exhibition a prize to be given for the best dressed flower, to be dressed at the place of exhibition, limiting the time of dressing to ten minutes. This would give all beginners a chance of seeing how it is done.

Doing away with dressing is out of the question. As I have before stated, growers in windy situations would have no chance. And again, there would always be found exhibitors who would dress a little, consequently it is best to let all do their best. But after all, "WYLD SAVAGE" may depend on one thing, and that is the best flower will win. I shall be well repaid if my few remarks induce but one "wyld savage" to

become a Carnation grower, and nothing would give me greater pleasure than to forward him a few plants with the best wishes of—A GILLYFLOWER.

YOUR correspondent, "D., Deal," has returned to the subject of dressing Carnations, and has introduced a string of comments from contemporary journals to prove that he is right. Some of the illustrations are unworthy of notice, and some of the statements made by your correspondent are not correct. The Carnation is not throttled by a "paper collar." A circular card with a hole in the centre is placed to show the flower to the best advantage; the hole in no instance presses the calyx. Does "D., Deal," really wish your readers to believe that all the delicate beauty of the petal is "destroyed, flattened, or pushed out" "by a series of instruments like a dentist's collection?" Does he believe it himself?

We next come to the assertion about mutilating the flowers. If "D., Deal," wished to show the weakness of his own position he could not have chosen a better quotation than the following:—"Mutilating the flowers with pincers and other instruments are a disgrace to lovers of flowers, and are a means of deceiving the public who are ignorant of such maltreatment; and it is no more right to take from or add to their flowers than it is for exhibitors of animals to take from or add to their tails." I have exhibited all sorts of flowers and have seen others exhibited. I love the flowers that I grow and give others credit for the same. If there is a bad flower on a Hyacinth spike the exhibitor cuts it off. If there are too many the exhibitor cuts a few out to allow those that remain to grow to their full size. He would do it if he did not intend to exhibit them because he likes to see well-developed pips, and he does not think he is doing wrong any more than when he uses the same scissors to thin-out the berries from his bunches of Grapes for the same reason.

An exhibitor of Orchids, Pelargoniums, Roses, &c., will cut imperfectly developed trusses or flowers from a plant they are exhibiting, and they will cut "run" flowers from a truss either on the home stage or for exhibition. Why? Because they love their flowers and like to see them perfect. This is not mutilating them. The judges at a Carnation show would disqualify mutilated flowers; even cutting off the top of a calyx disqualifies; a split pod disqualifies. No exhibitor ever took half the petals from a Picotee as stated. Petals are very seldom removed, but a self petal in a Carnation would disqualify, and an exhibitor wisely removes it.

Does this bear any relation to mutilating an animal? "D., Deal," wishes to exhibit a donkey, let us say, and the judges go in for certain points, even to the colour; but a hair or two is wrong on the animal's coat, and if left in would disqualify. I fancy he would pull them out. He would do it to hide a blemish, not to make one. But suppose its ears are too long and he trims them, or he cuts off half the tail to bring it down to the regulation standard, what then? The judges would disqualify, and the Society for the Prevention of Cruelty to Animals would also have something to say. You may brush and dress your donkey, but you must not mutilate him.

Your correspondent admits that it is right to arrange the petals of the flower. In most cases this is all that is done. No exhibitor adds to a flower, and only a tyro would extract petals in the wholesale manner suggested, or he would not have a place on the prize list.—J. DOUGLAS.

P.S.—An exhibitor brought a collection of Hyacinths to Kensington once. The spikes were not dressed, and if they had been exhibited as they were would have found no place on the prize list. I dressed them for him in the usual way, and the exhibitor gained the first prize. Who ought to have received it? I did not. He did not say it was wrong to dress them, and he retained the prize money. Those who live in glass houses should not throw stones.—J. D.

THE FRUITERERS' COMPANY.—In pursuance of an agreeable annual custom the Wardens and Court waited upon the Lord Mayor and the Lady Mayoress on the 17th inst. at the Mansion House and presented them with a splendid assortment of the fruits in season. The gift, which was tastefully laid out in the saloon, included Pine Apples, Strawberries, Grapes, Peaches, Melons, Apples, Pears, all of the first quality. The presentation was made by Mr. Alderman Knight, the acting Master, who spoke of the custom as an act of respect to the Chief Magistrate as the head of the Corporation with which the City Companies were so intimately connected, and who wished that

the usage was followed by the richer and larger guilds, whose offerings would be infinitely more worthy of the acceptance of the Lord Mayor and the Lady Mayoress. In reply the Lord Mayor thanked the Company warmly for their gift, and also, in accordance with custom, invited them to dine with him at the Mansion House.

SINGLE DAHLIAS.

For a number of years past raisers of new varieties of Dahlias have devoted their attention almost wholly to the raising of double flowers, and have reached a point of excel-

lence to which it appears difficult to make any further advance. New colours or combinations of colours may be produced, but as far as regards shape and symmetry of the blooms little, if any, improvement can be expected. There is, however, a wide field open for raising new varieties having single flowers, and we shall not be surprised if single Dahlias do not become popular.

We last year referred approvingly to two rows of single Dahlias, scarlet and yellow, in the nurseries of Messrs. Veitch and Sons at Chelsea. No one could see those varieties as there grown in quantity without being impressed by their chaste yet glowing beauty. Mr. Cannell also, at the last

Fig. 38.—DAHLIA PARAGON.

meeting of the Royal Horticultural Society, exhibited beautiful blooms of these varieties under the names of *coccinea* and *lutea*, and also submitted a third variety, named *Paragon*, which by the richness of its colours and its exquisite form caused something like a sensation in the Council-room. This striking Dahlia was unanimously awarded a first-class certificate, and the honour has not this year been bestowed on a flower more rich in colour and more distinct—so distinct that it was considered by some of its admirers as a species: it is, however, probably a variety of the old crimson fertile-rayed Dahlia *superflua*. In every point it is an improvement on *D. superflua*, which has long pointed petals that do not overlap; the variety *Paragon* has smooth rounded petals, which, besides overlapping, have a slight but elegant reflex, contributing

greatly to the refinement of the flower. The colour, too, is intensely rich—a glowing velvety maroon, each petal having further a well-defined narrow margin of reddish claret. The petals are also of good substance, and the flower is perfectly round like a *Zinnia*. The yellow and scarlet varieties noticed also possess the same excellence of form, and are singularly clear in colour. The accompanying figure of *Paragon* shows the form of those single Dahlias and how much they are in advance of the starry single flowers of our forefathers.

The plants are free in growth and floriferous, and are eminently suited for forming back rows in borders, while the flowers are admirably adapted for the decoration of vases, &c., for which double flowers are too heavy and formal. A white single Dahlia having the same good qualities of form and

substance of petals as the varieties now alluded to would be a valuable acquisition. There is no reason why it should not be forthcoming; but in the meantime let the brilliant trio referred to be increased, for assuredly they are worthy of extensive cultivation.

CHELTENHAM AND COUNTY OF GLOUCESTER ROYAL HORTICULTURAL SOCIETY.

THE autumn and final Show of the season of this Society took place on the 18th inst. at the Montpelier Gardens, Cheltenham; and although the weather in the morning was inauspicious, before the opening of the Exhibition at two o'clock the sky cleared, and a full measure of autumn sunshine helped to set off to the best advantage the yet bright green tints of the lawns and foliage in this pretty and well-kept resort, the grounds looking almost as fresh as in early summer. It has seldom been my fortune to visit a better, although I have seen many larger shows, and the enormity as well as the quality of some of the individual exhibits, especially in the vegetable and salad departments, were far in excess of those usually met at horticultural shows; and if the exhibitors do not find their efforts an overtax it is not in the interest of the sight-seeing visitors that such efforts should be contracted, for the improved effect of such masses over many small collections and specimens is undeniable. It is hardly possible to have too much of a good thing, but it is questionable whether eventually sound progress in horticulture can be attained or even advanced by the exhibition of baskets of salads 8 feet high by 6 feet in diameter! Here half the space in a large marquee had to be devoted to four baskets of salad; and about a bushel of Brussels Sprouts, two dozen large heads of Celery, twelve fine Broccoli, seven brace of Cucumbers, 120 Tomatoes, and upwards of a peck of Capsicums, each constituted a dish of vegetables; Potatoes, Carrots, &c., in proportion! In former years I have seen the profusion of good things coming from the Cheltenham *Jardins Potagères* but the prodigious masses exhibited on this occasion show that the spirit of emulation in this department of horticulture has lately at Cheltenham been well kept alive there. It may be that vegetarianism is getting dominant in the garden town: certain it is also that the many showy and good fruiterers' and greengrocers' shops in the place exhibit a Californian profusion of fine vegetables, and there must be, what I am looking for, some good garden land in the locality. The question, however, is, Will not this gigantic scale of exhibiting tend to bring round a counter current? and is it not frequently one of the ultimate causes of failure of horticultural shows and the good they are intended to promote? It is only those who have been behind the scenes who know the extent of ground, the labour, and the cost of producing such collections; and I have known an enthusiastic amateur and exhibitor decline further exhibiting on the ground that his gardener dug up an acre of Potatoes on one occasion for a show dish! And I fancy that a rood of well-cultivated garden ground would not suffice for the origin of some of the Cheltenham exhibits.

In tent No. 1, the first prize for a collection of vegetables, nine dishes, was awarded to Mr. Turk, who had good Early Rose Potatoes, Cucumbers, Broccoli, Tomatoes, red and yellow Capsicums, Brussels Sprouts, Turnips, and Intermediate Carrots. Mr. Holder was second, having good Cucumbers, Artichokes, Parsnips, and White Stone Turnips. For the six dishes, Mr. Arkell, gardener to A. J. Skinner, Esq., whose exhibit was even larger in quantity and as good in quality as those in the previous class, the collection occupying a space of about 12 feet by 8. He had Fenn's International Potato, fine; Cucumbers, Tomatoes, white Celery, red and yellow Capsicums, and Intermediate Carrots. Mr. Crump, gardener to J. S. Surman, Esq., was second, including in his lot good Peas, Broccoli, and Tomatoes; and Mr. Reason, gardener to J. B. Winterbotham, Esq., was third. Peas were well shown by Mr. Arkell and others, the best being Ne Plus Ultra, Omega, G. F. Wilson, and Supreme. For the collection of salad Messrs. E. Smith & Son, Cheltenham, were first with a very large and varied basket quite up to the usual Cheltenham quality. The second and third prizes went to Mr. J. J. Smith and Mr. Holder respectively. They had rather smaller but equally good collections. Very fine and well-ripened Giant Rocca Onions, almost equal to the best Lisbon, came from Mr. Holder, Mr. Turk having also very good White Spanish.

Fruit was good and largely shown. The first prize for a collection of six varieties was awarded to Messrs. E. Smith & Son, the second and third equally to Mr. Moorman and Mr. Green, the latter having some very fine Black Alicante Grapes, bunches large, finish and colour good. The prize collections in this class are given for the annual dinner of the Society. For the collection of four varieties Mr. Mayo, gardener to G. Makgill, Esq., Cheltenham, was first, having recently-cut and old Bowood Muscat Grapes in the same dish. Good Grapes also came from Mr. Hunt, gardener to F. Butt, Esq., who had three well-finished but not large bunches of Black Hamburgs, and was placed first. For the single dish of white Grapes Mr. Wiggins, gardener to Alderman Freeman, was first; and for the two varieties of black,

three bunches of each, Mr. Green was first with large and well-coloured Black Alicante and good Black Hamburgs. In the class for two varieties of white Grapes Mr. Moorman was first with White Syrian and a distinct white Muscat seedling, the berries being large and almost pear-shaped, but not quite ripe. Peaches and Nectarines were good. J. L. Anley, Esq., and Mr. Green having Rivers' Princess of Wales Peach, fine; J. Gall, Esq., also having Pitmaston Orange Nectarine, good. Mr. Mayo showed an Apple called Lord Clyde, of the Golden Noble type, in conjunction with Bon Chrétien Pear, and was placed first in the class for a dish of each. Some pretty specimens of Apple Orange Pearmain were also shown, but the flavour was poor and pasty.

Potatoes were not so good as usual for the season. In the open collection, number of varieties, the first prize was awarded to Messrs. E. Smith & Son, who had a large collection of about fifty varieties, and amongst them good specimens of Gloucestershire Kidney, McKinlay's Pride, Bountiful, Webb's Surprise, King of Potatoes, Dalmahoy, large; Early Rose, Climax, and a variety called Smith's Seedling, in appearance very much like Scotch Blue, but the collection in the whole was irregular and badly matched. Mr. Barnes was second, showing a less number of varieties but a very even lot, all being good alike. He had Schoolmaster, International, Wheeler's Safeguard, Bountiful, Royal Ashleaf, Scotch Champion, Snowflake, Early Don, Rector of Woodstock, Blanchard, Ashtop Fluke, Bresee's Prolific, Model, Red Emperor, American Breadfruit, Early Rose, Imperial Kidney, Giant King, Climax, Queen of Flukes, Late Rose, Manchester, and Sutton's Magnum Bonum, of which Potato I hear from many quarters marvellous reports as to its good quality and productiveness. Mr. Crump was third, having good examples of William Earley, Safeguard, Peachblow, Rivers's Ashleaf, Sutton's Perfection, Fenn's Early Market, Red-skin Flourball, and Gloucestershire Kidney.

Tent No. 2 was in a blaze with the most brilliant, best grown, and profusely bloomed lot of Zonal Geraniums I have seen for some time. They were staged very effectively on a low platform about 1 foot 6 inches high. Each plant was about 4 feet in diameter, and the *tout ensemble* was very fine. The best twelve came from Mr. Rose, gardener to Mrs. Boulton, who had Col. Holden, very good; De Lesseps, Acme, La Tournaise, Madame Werle, Dame Blanche, Mrs. William Paul, Master Christine, and Peeress. Mr. Cypher was second, having striking specimens of Santley, Adelina Patty, and Woman in White. Mr. A. Mansfield was third; Comet, Mrs. H. Cannell, Mrs. F. Fenn, Polly King, and The Shah being the best.

In cut flowers good autumn Roses were shown. A fine stand of twelve varieties, not less than three trusses, coming from Mr. Shaw (it is a matter of regret that the addresses of the exhibitors were rarely given). He had Marquise de Castellane and Duke of Edinburgh very fine, also good blooms of Prince Camille de Rohan, Comtesse d'Oxford, Beauty of Waltham, Baronne de Rothschild, La France, Annie Wood, Gloire de Dijon, and Charles Lefebvre. Mr. Jackson, Blakedown Nurseries, Kidderminster, was second, having W. Wilson Saunders fine, and nice blooms of Capitaine Christy, A. Rigotard, Paul Neyron, Marguerite de St. Amand, and Souvenir de Paul Neyron, Teas. Mr. Garraway, Bath, was third, Maréchal Niel, Perle des Jardins, Catherine Mermet (fine and shell-like), and Comtesse d'Oxford being his best. A stand of twenty-four very clean and magnificent blooms of Maréchal Niel not for competition also came from Mr. Garraway, and to which an honorary prize was awarded. These appeared quite equal to the fine blooms usually seen at the Crystal Palace Shows in June.

Dahlias were very good, the finest stands coming from Mr. Jackson of Kidderminster, who was first both for the twenty-four Show and twelve Fancy. It may be of service to growers and amateurs to have a list of those shown by this successful grower. His twenty-four Show varieties consisted of John W. Lord, Henry Walton, Herbert Turner, Admiration (Keynes 1878), Burgundy, Perfection of Primroses, Charles Leicester, Acme of Perfection, Henry Bond (Keynes 1878, a distinct mauve), Empress Maud, Vice-President, Monarch, Artiste, John Neville, Criterion, Mrs. John Downie, Thomas Goodwin, John Bennett, John Standish, Royal Purple, Rev. Dr. Moffat, Jeanie Grieve, Leader, and Lady Herbert. Mr. Jackson's twelve Fancies were George Barnes, Hercules, John Lamont, Richard Dean, Henry Glasscock, Regularity, John Saunders, Letty Coles, Mrs. Saunders, Egyptian Prince, Flora Wyatt, and Fanny Sturt. Mr. Shaw was second for the twenty-four Show, having very fine blooms of Woman in White and Herbert White, two large pure whites; Messrs. Heath and Son being third, Lord Derby and Charles Backhouse being very brilliant and conspicuous in their stand. For the twelve Fancies Mr. Shaw was second, and Mr. Barnes third.

Messrs. Heath were awarded an honorary prize for seedling Dahlia Sir Stafford Northcote, bronzy orange of good form, but as shown slightly flat in the centre: more, however, will probably be heard of this, as it is likely to be an advance. Messrs. Heath had also a large stand of a new white bouquet Dahlia, Guiding Star.

Asters were remarkably good, and formed a great contrast to

those shown at Northampton. Mr. J. Walters, who has latterly taken a leading position with this flower, was first for twenty-four French, and he has rarely been in better form. Messrs. Heath were second and Messrs. Garraway third, all showing well. For twenty-four German Quilled Mr. Walters was again first with the good old Globe sort, and had some very distinct varieties; Mr. Garraway was second, and Mr. Crump third.

For table decorations Mr. A. Mansfield, gardener to W. Fletcher, Esq., was first, E. Pilgrim, Esq., second, and Mr. Smith, gardener to Mrs. General Tickhill, third. A very beautiful bouquet from Miss Cypher was awarded first, Mr. Jackson being second, and Mr. Mayo third.

In the large plant tent a complete hedge of Fuchsias was formed down each side, most of the plants being from 4 to 6 feet high and well grown in the West of England style. For six varieties Mrs. Tickhill was first, and for four varieties Mr. Mayo. By far the best habit and most floriferous of the darks was Rhoderick Dhu, somewhat after the Souvenir de Chiswick style. The best light-sepalled varieties were Rose of Castle, Wiltshire Lass, Alexandrina, Lustre, and Evening Star. White Perfection, although neither a large nor a perfect flower, is very distinct and floriferous as a white-corolla variety.

In Ferns and Mosses some very fine specimens were shown. Mr. Hamlett, gardener to E. Pilgrim, Esq., was first, and Mr. Cypher second; and for twenty-four British Ferns Mr. Hamlett was again first, having unusually large and well-grown plants, several of the specimens being from 3 to 4 feet in diameter and in effect equalling the exotic species. The most striking were *Polystichum angulare* proliferum and *P. angulare* Patey, *Osmunda regalis cristata*, *Scolopendrium ramosum*, and *Lastrea Filix-mas cristata angustata*, very curious and distinct.

Lastly, the stove and greenhouse plants, for which Cheltenham has notably for some time past been an important centre, were, as it would be anticipated, remarkably fine, and larger, choicer, and better-grown plants are rarely met with at the South Kensington and Regent's Park exhibitions than those exhibited on this occasion by Messrs. Cypher, Pilgrim, Heath, and others. For the collection of eight Mr. Cypher was first, and it is marvellous how little his plants, which for weeks past must have been so frequently on the move and have been almost half the time in the dark, appear to show the effect of their travel. Mr. Pilgrim was second with large plants, little if in any way inferior. For the collection of four varieties Messrs. Heath were first, and Mr. Skinner, gardener to E. Armitage, Esq., second.

In the class for thirty plants grouped for effect a large space was well occupied by Mr. Pilgrim, who was first; and by Mr. Cypher and Messrs. Heath, who were respectively second and third. A fine specimen of the Turk's Cap *Melocactus* from J. Robertson, Esq., attracted attention, and there were many other interesting points in the Show, but time prevented my further encroaching upon your space.

The annual public dinner took place in the evening at the Plough Hotel under the presidency of W. N. Skillicome, Esq., and this year the occasion was improved upon by the presentation to Mr. H. J. Cochrane of the *Cheltenham Chronicle*, the worthy Secretary of the Society, of a very handsome illuminated testimonial on vellum, with a gold watch and appendages of the value of sixty guineas, from a large number of horticultural and other friends, in recognition of his valuable services as Secretary of the Society during the past twenty-five years. Not a little of the success and prosperity which the Cheltenham exhibitions have attained is due to Mr. Cochrane's exertions. May he long yet continue to promote the horticultural interests of the town and county.

It is to be regretted that at these shows few beyond subscribers and the *élite* of the neighbourhood are enabled, in consequence of the restrictive prices of admission, to appreciate such really good specimens of horticultural skill. If the Show were opened at one o'clock, or even earlier, as is done in some places, the subscribers would probably be as well pleased with an earlier view, and in the evening with a low admission fee the masses from the two large towns of Cheltenham and Gloucester would most likely advance the interests of the Society, even in a financial way, as well as its means for good in a horticultural point of view.—T. LAXTON, Bedford.

AUTUMN ROSES AT WALTHAM CROSS.

It is a little difficult to take notes of Roses in a heavy thunderstorm, whilst you hold an umbrella in one hand and a notebook in the other, and all the time the rain is soaking you to the skin; but such was my fate on August 30th, and if these notes are found to be less copious or less satisfactory than those on other nurseries I hope your readers will consider the cause and be merciful in their judgment.

This was my first visit to Mr. William Paul's nursery, and I hope it will not be the last. In fact I would rather not count it as a visit at all, as I was so very uncomfortable and so soaked with rain that I could not call on Mr. Paul himself, but had to hurry back to town.

The nursery is approached from the platform of the railway by a very pretty walk. On each side are planted Roses, dwarfs in a bed to the left and standards to the right. After following the railway fence for 50 or 60 yards you come to the nursery. This is a very extensive one, but almost on a dead level, so that you cannot appreciate its size all at once. The arrangement of the ground struck me as being particularly good.

From the walk which bordered the railway broad grass paths branched off, which led right through the nursery. These were kept close shorn by the machine and looked well. On each side the paths were wide beds containing about twenty dwarf Roses of the same variety, and at the back of these were standard Hollies at regular intervals; behind these were in one case fruit trees, in another Conifers, and further up in the nursery great collections of Roses and Rose stocks of all sorts. There were a very fine lot of blooms in spite of the weather, more especially on the dwarfs. All the varieties I noticed elsewhere as being good autumn bloomers were here well represented. I had no opportunity of seeing the seedlings on account of the weather, but I know Mr. Paul has many very promising ones.

Of the autumnal bloomers, here as at Cheshunt the Teas were the best; next to them came the Bourbons. These two varieties cannot be too highly recommended to amateurs as autumnal bloomers. I cannot imagine anything looking better than would a long bed of Bourbons. A very good selection would be the following, and anyone can verify the truth of what I say by taking a return ticket to Waltham—*Modèle de Perfection*, Sir Joseph Paxton, Baron Gonella, Bourbon Queen, and Souvenir de Malmaison. In another bed I would plant Teas and Noisettes, consisting of the following—Rubens, Niphetos, Marie Van Houtte, Madame Berard, Louise de Savoie, Belle Lyonnaise, Céline Forestier, Madame Falcot, Safrano, Triomphe de Rennes, and Souvenir d'un Ami: all these are exceedingly free bloomers now.

Of Hybrid Perpetuals the best bloomers as seen at this large nursery are: Whites and blush—Madame Rothschild, Capitaine Christy, Boule de Neige, and Mrs. Bellenden Ker; rose shades—Paul Neyron, Dupuy Jamain, Edouard Morren, Hippolyte Jamain, Alfred Colomb, and Marie Baumann; dark—Duke of Edinburgh, Duke of Wellington, Fisher Holmes, Sultan of Zanzibar, Annie Wood, Pierre Notting, and Camille de Rohan.

I think I have not seen this year such lovely blooms of my great favourite Marie Van Houtte as I saw at Waltham. All the Teas, however, were doing very well. Mr. William Paul never exhibits for competition. He grows very largely, and has now a stock of 500,000 plants for sale, but he does not care to undertake the labour and trouble of exhibiting at our great contests. His name is so well known that he can always sell his plants without exhibiting, but at rare intervals he has a show of his own which a little astonishes the rosarians. At the Royal Botanic, for instance, he once clothed a bank with cut blooms set in moss after the French style, and at the Crystal Palace and other places in the spring of the year he has made wonderful displays with his Roses in pots. His place is a most convenient one to get at, and if the weather ever does take up I should advise my brethren who wish to see autumnal Roses to pay Mr. Paul an early visit.—WYLD SAVAGE.

SUTTON & SONS, READING.

No one can approach Reading by either of the iron roads from London without seeing something of "Suttons, Seedsmen." Acres of Cabbages, plantations of Potatoes, mountains of manure, relieved with Pampas Grass avenues, all proclaim the region of the great seedsmen no less than the notice boards; while in the good town itself those mythological monsters which have been fighting for the crown all these years, and are as far as ever from settling which is to have it, surmounted on the magnificent buildings in the market-place indicate head quarters.

Sutton is a name known widely for good at Reading. I am almost tempted, when I look round and see that coffee palace with its splendid hall appropriated to religious meetings, or hear of fresh charities, to repeat Mr. Pope's inquiry—

"Who hung with woods yon mountain's sultry brow?
From the dry rock who bade the waters flow?
Whose causeway parts the vale with shady rows?
Whose seats the weary traveller repose?
Who taught the heaven-directed spire to rise?
'The Man of Ross,' each lisping babe replies."

But I believe happy Reading has more than one Man of Ross.

Certainly the devout dedicating of a fixed portion of income has brought with it an increased portion of income to dedicate. But my mission at Reading was to see Messrs. Suttons' Roses; and here I am in the position of Canning's needy knife-grinder. Story, Mr. Editor! I have none to tell you. It is much like that second chapter of the History of Iceland, "On the snakes of Iceland," "There are no snakes in Iceland." Alas! there are now no Roses at Suttons' except a choice few upon Manetti and seedling Briar, just to show how well they once were and might be grown. Seed-saving and seed-selecting now prevail. The Roses are gone, the fruit trees are going, the glass has been annexed for series after series of serials. About forty acres are under cultivation in the approach to Reading, and some eight acres more at the London Road gardens, and in each seed-selecting reigns supreme.

The courteous and highly intelligent foreman Mr. Martin did his best to console me, inwardly scandalised, I am sure, by my ignorance and indifference, as he showed me what had replaced the Roses—beds of the most unblushing and aggravating Dahlias, amazing Asters, huge Hollyhocks, and other heartless supplanters of the choice standards of better days. In one place, however, he did fix my attention, and that was in the splendid house of Cyclamens, these being at the present the reigning beauties of the nursery. Great attention has been given of late here to hybridising, special brushes being used for special sorts of pollen, all the finest seedlings being selected and set aside for breeding from, and the results show already a great stride forward in excellence. These charming three-months-in-flower denizens of the greenhouse are attaining here an excellence I never saw equalled. The variety of leaf attained appears yet more remarkable. In the persicum house there were several that might be called maculatum, but in the house of the giant species these were really gigantic, leaves of wonderful size and most beautifully variegated. I anticipate a great demand as these come into commerce.—A. C.

TRAPPING WASPS.

WASPS are very numerous this season. Many of our Peaches, Plums, &c., on the open walls were destroyed by them. Where there is much fruit to tempt them on open walls it is no easy matter to induce them to enter any trap. I find the best way is to allow them to congregate in the inside of the fruit, and then go round the wall with a pair of gloves on and firmly press all those fruits that are filled with wasps, so as to kill them. When allowed to eat one fruit they generally prefer this to beginning on another, and it is surprising how quickly a crowd of them will eat the centre out of any fruit and leave nothing but the skin; but it is just before the inside has been entirely cleaned out that is the time to kill them. Sometimes thirty and forty may be found inside at a time, and to kill this number is worth losing a few fruit.

The vineries have also been a favourite resort of these pests. Although all kinds of netting may be put over the ventilators they generally find their way inside by some small hole or other. The plan of hanging up bottles filled with sour beer is not such a good one as having some jam mugs set here and there with a little jam in the bottom of them made into syrup with water. They go to feed on this and drop into it by the dozen.

Last year a story appeared in some of the gardening papers that wasps would not live in a house where Tomatoes were growing. We have Tomatoes surrounding the ventilators, and the wasps came through amongst the leaves to reach the Grapes. Wherever there is a little space at the bottom of the walls it is filled up with Tomatoes, and some of their leaves are touching the fruit, yet the wasps attack them the same as if there was nothing of the kind there.—A KITCHEN GARDENER.

NOTES AND GLEANINGS.

WE regret to find by a circular that has been issued by the Local Committee of the late HORTICULTURAL SHOW HELD AT PRESTON that there is a large deficit of nearly £1500 after paying all expenses. This deficiency is attributed by the Committee to "the wet weather of the first two days, and the presence of the Lord Mayor of London at that time in Blackpool on the occasion of the opening of the Winter Gardens." We have no doubt that the appeal issued by the Committee to the town and county will meet with the response it deserves, and that the town and Lancashire will not allow it to be said that the first failure of the provincial shows took place in 'proud Preston.'

— MR. IGGULDEN and another correspondent recently alluded to ANTS AS INSECT DESTROYERS. Testimony of the same nature now comes from the land of Olives. *L'Italia Agricola*, in speaking of the cultivation of fruit trees, says that the cultivators of Mantua are in the habit of forming a colony of ants every spring time at the foot of each Olive tree, with the certainty that the tree will remain untouched by any other insects. The general opinion is that ants are enemies to fruit trees, but in Ratzeburg it has long since been proved that ants destroy larvæ and chrysalides, and that they only touch such fruit as has been picked by the birds.

— UNDER the heading of "a novelty indeed" the *Rural New Yorker* prints the following relative to a BLUE GLADIOLUS. "We were asked by a friend one day last week to call at the sale-rooms of Young & Elliott, of this city, to see a blue seedling Gladiolus. It was among an extensive collection of seedlings of this beautiful flower raised by Mr. C. L. Allen of Queens, L.I. Seeing that our friend was in earnest, which we doubted at first almost the same as if he had spoken of a blue Rose, we hastened to the place of exhibition. The individual flowers of the spike were rather large and well opened, and the colour of all the petals except the lower ones was a uniform greyish-blue or lavender, without streak or blotch. The lower ones were marked with a tongue of a deeper colour—a deep blue inclining to violet. The upper part of the spike alone was exhibited; the flowers of the other half, left upon the flowering stalk, had been pollinated in the hopes of securing seeds." What do the Messrs. Kelway think of this "pollenated" novelty?

— MR. H. J. ELWES, F.L.S., in his splendid Monograph on the Lily genus, notices as a curious fact "that all the AMERICAN LILIES, though varying remarkably among themselves, differ entirely in their bulb structure from those of Europe and Asia, and the same peculiarity is noticeable among the American species of Fritillaria (Crown Imperials), which, as far as we know them, have bulbs of small white and granular scales loosely attached to a solid central axis, from which the stem springs. Of all the Old World Lilies and Fritillarias only two (Lilium arenaceum and Fritillaria kamschatkensis) resemble their American congeners in the formation of their bulbs, and both of these are restricted in their geographical limits to the shores of north-eastern Asia, which have many affinities, both botanical and zoological, with the Pacific coast of North America."

WORK FOR THE WEEK.

KITCHEN GARDEN.

CHOOSE a dry day for giving the earliest crops of Celery a final earthing-up, well batting the sides of the banks of soil so as to exclude rain as much as possible. The work is much facilitated by tying the stalks together with matting just below the leaves, and not too tightly, or, what is better, use the "Wortley collar." In heavy wet soil sawdust is a good material for earthing with, and ashes also are good and not liked by either worms or slugs. The best material of all is cocoa-nut refuse, and is a capital dressing for heavy soil. The main and late crops should only have a moderate earthing as yet, a little soil placed around the base of the stalks doing much to prevent injury from winds. See to the tying-up of Cos Lettuce and Endive in favourable weather, completing the planting of the latest crops in pits or frames without delay. Have in readiness any spare lights or covers for placing over Lettuces or Endives coming on for use in case of sudden frosts. Cauliflowers coming in should have a few of the outer leaves broken over the heads to keep them in good colour, and as protection from heavy rains and sudden frosts. French Beans are often destroyed by a single night's frost, which may often be prevented by having at hand some protecting material to ward off if necessary the evil effects of one or two cold nights, thereby prolonging their bearing probably for some weeks longer. This crop, however, often suffers as much from prolonged cold and wet as anything else; therefore cover wherever practicable with a ground vinery, admitting air liberally, throwing mats over the lights in case of frost. Parsley in frames, or that in an open yet sheltered situation intended to be covered with frames, should now have the shelter of glass when necessary, removing all yellow or decayed leaves, and if the plants are at all crowded thin them well out. Some charcoal broken up rather small and sprinkled over the surface will be beneficial in arresting damp and mildew. The lights should remain off during all mild weather, and if it be necessary to employ them on account of frost at night remove them in the daytime. If no frames are available take up some of the strongest spring-sown plants, planting them in deep boxes or pots, standing in a shady position for a few days, subsequently removing them to a sheltered situation, and eventually placing

them in a vinery from which the Grapes are cut, for affording a supply in severe weather. Some of the August-sown Chervil, carefully lifted and planted in boxes or pots and treated similarly to the Parsley, will be found very useful in winter. Prick into handlights Cauliflower plants from the August sowing so soon as they can be handled, selecting the strongest. The situation should be a warm but open one, and if the soil be light take out a spade deep and replace it with rather strong turfy loam to insure sturdy growth. The plants must have full exposure, employing the lights only in case of frost. The smaller plants prick out in cold frames during the second week in October. Sow Radishes upon a warm border.

FRUIT HOUSES.

Vines.—Late Grapes ought now to be fully ripe; if, however, they are not apply fire heat until they are thoroughly ripened, there being more to fear from having them immature than over-ripe. Thin-skinned kinds of Grapes, as Hamburgs, will require frequent looking over for the removal of decayed berries. Damp being the cause of this evil expel it, or what is better prevent it by fire heat in the daytime with free ventilation, turning the heat on in the morning and off again in the afternoon, as a too warm atmosphere at night is undesirable. Vines that ripened the fruit at midsummer and afterwards will now probably have all or nearly all the fruit cut. If there is any doubt as to the condition of the wood as to ripeness, turn on the heat by day with abundant ventilation and off at night, not, however, reducing the ventilation. This will induce the Vines to ripen-off kindly, lateral growths being kept well pinched. Young or this year's planted Vines allowed to ramble will have formed strong canes and may have a part of the surplus growths removed, being careful not to damage the principal leaves—i.e., those at the base of the buds on the main rods, maintaining a warm dry atmosphere freely ventilated until the wood is brown and hard, then allow the Vines to go to rest. Vines in pots other than those intended for very early forcing should now have the wood brown and hard, and be placed against the south side of a wall or fence, but it is not desirable to allow the roots to be deluged with heavy rains. Lay the pots on their sides, or cover them with some material to throw off the wet.

Peaches and Nectarines.—The second early house will have the trees in an advanced state, the foliage turning yellow and falling. The border, if the roof lights are not moveable and have not been removed, must not be allowed to become too dry, but should be kept in a moist state. Syringing should be discontinued, but in the later houses with the foliage still fresh an occasional syringing will be necessary to free it of red spider. When the fruit is all gathered from the trees in the late houses the shoots should be thinned out where overcrowded, as well as those which have borne fruit, cutting them out to a successional shoot at the base. It will be desirable to turn the heat on by day if the wood be at all un-ripe, admitting air freely, but turning the heat off at night. The borders must not be neglected for water, as lack of that element would only tend to premature ripening and immature buds. In the latest houses of all, which are not nearly so frequent as they deserve, the late kinds will be ripening or ripe, and will be much better flavoured than that grown against open walls. In the case of dull cold weather a little fire heat will be necessary to ripen them thoroughly and afterwards to harden the wood, accompanied with abundance of air. Late Admirable, Stirling Castle, Walburton Admirable, Rackmackers, and Mr. Rivers's seedlings—Princess of Wales, Sea Eagle, Lord Palmerston, Radclyffe, Golden Eagle, and Osprey, to which must be added the Salwey, are all fine late sorts. Desse Tardive, though a good late Peach, is superseded by Radclyffe. These October Peaches are very valuable, the Salwey often not being ripe until late in the month.

Peach Trees in pots, which are desirable for affording very early fruit, should be repotted if it be required without further delay; but it is not desirable to do this unless the trees have been forced for some years, and have grown in size disproportionate to the size of the pots. The roots should be disentangled around the sides of the ball with an iron prong or fork, the drainage removed, and the surface soil picked out amongst the roots. If larger pots are required do not give a large shift, in no case larger than to admit of an inch or two of fresh soil around the reduced ball. In many cases the trees may be returned to the same size of pot. Provide efficient but not excessive drainage; ram the compost (turfy loam laid up for two or three months) to reduce the grass chopped up moderately small, adding a tenth part of old mortar rubbish and a fifteenth part of half-inch bones, all well incorporated; this should be pressed very firmly around the ball, leaving about an inch clear space for holding water. A good watering should then be given, the pots stood upon a hard bottom impervious to worms, placing ashes around the pots to their rim, and cover the surface of the pots 3 inches deep with litter or cocoa refuse. The situation should be an open but sheltered one, where they may remain until required for forcing. Trees only a year or two in pots will not require potting or interfering with at the roots, but should be stood outside, plunged as advised for those repotted after removing the old surface dressings, and applying a little fresh soil just to cover the roots. Some of the best for

this purpose are Early Beatrice, Early Alfred, Hales' Early, Early Grosse Mignonne, Merlin, Royal George, Grosse Mignonne, Violette Hative, and Noblesse. Of Nectarines Lord Napier, Stanwick Elruge, Elruge, and Violette Hative.

Melons.—Be careful in the application of water; but the last batch with the fruit swelling must not be allowed to become dry at the roots, keeping up moderate moisture by damping every morning and at closing time, earthing up the plants as required, removing all superfluous growths as they appear, maintaining a temperature of 70° to 65° at night, 70° to 75° by day, up to 85° or 90° with sun, keeping the bottom heat at about 80°. Fruit ripening will be the better of a little extra fire heat and a little air constantly; a dry state of the roots, but not so dry as to cause the leaves to flag, accelerates the ripening process. In dung-heated pits and frames no water will be required after this; keep the frames well lined, admitting a little air constantly, which with the fruit raised well above the surface of the bed will do much to impart flavour. Any fruit it is wished to keep for a time should be cut when changing with a good portion of stem and be kept in a dry airy room, or if wanted ripe at once they may be placed in a warm airy house in the full sun, and they ripen better than in frames or pits devoid of artificial warmth.

Cucumbers.—The autumn fruiterers must have careful attention, affording copious supplies of liquid manure, removing superfluous male blossoms and tendrils, avoiding overcropping, and not allowing the fruit to hang too long. The syringe should only be employed at closing time on bright afternoons. Earth-up the roots as the plants advance in growth from time to time. Pinch-out the growing point one or two joints beyond the fruit, going over the plants at least once a week for that purpose, retaining no more foliage than can be fully exposed to light. All waterings must be given at the same temperature as that of the roots. Pot off the winter fruiterers directly they are large enough to be handled, plunging the pots in bottom heat until the plants are established, then raise them near the glass, maintaining a temperature of 70° at night, 75° by day, with an advance from sun heat of 10° to 15°. The fermenting materials, if such are used for bottom heat, must be in preparation for the formation of the beds for this batch in due time. For producing a good supply of fruit in late January or early February seed should be sown at the beginning of next month. Plants in dung-heated frames or pits must have the linings renewed as required, the foliage kept rather thin, the Vines well stopped, and no more water should be given than to secure healthy moisture for the roots, placing mats over the lights on cold nights.

PLANT HOUSES.

Stove.—Amarylises like a long season of rest, both the deciduous and evergreen or Hippeastrum section; and though the former lose their leaves it is undesirable to gradually dry them off, it being as injurious to them to be allowed to become dust-dry as to those that retain the foliage in winter. The latter must not be allowed to become so dry when at rest as to cause the leaves to flag, or they will soon perish, dryness at the roots of either description of plants materially weakening the bulbs. They should be kept on shelves with the soil moderately moist. *Urcollina aurea* will be throwing up for bloom and must be kept moist, for though it blooms before the leaves the soil must not be allowed to become dry. The late *Achimenes* and *Gloxinias* should have positions near the glass and not overwatered, yet enough to keep the soil moist, or the flowers will be short-lived. Any that are becoming shabby should be placed in light situations and dry, with a little water occasionally until the tops go off. *Gesneras* of the zebra section and *Tydas* should have light airy situations, a rather warm temperature and moderate moisture, affording them weak liquid manure occasionally. *Eucharis* wanted to flower late should be kept rather dry in a temperature of 55° to 50°, a good growth having previously been made.

Aquatic plants are useful alike as objects of beauty, also affording flowers for cutting from. *Nymphaeas* *cærulea*, *cyanea*, *rubra*, *dentata*, and *Devoniana*, *Nelumbium speciosum*—are all capital for the base of stands in table decorations. *Limnorcharis Humboldtii*, *Pontederia crassipes*, *P. cordata*, *Pistia stratiotis*, and *Papyrus antiquorum*, the latter and *Nelumbium* being upright-growing. A tank of about 12 feet in diameter with a depth of about a foot of rather strong turfy loam will answer their requirements, with from a foot to 18 inches' depth of water. The *Nymphaeas* are best grown by themselves, as the upright growers require space. They require very little attention and are very interesting, flowering over a lengthened period.

Nepenthes are coming in for their share of attention, and no plants are more deserving. This is undoubtedly the best time to secure stock, as they suffer considerably in transit if removed during growth or in cold weather. The best description of house to grow them in is a low span, such as is employed for growing Cucumbers, for the practice of growing them at a distance from the glass and heavily shaded is now exploded. All they want is shade to prevent scorching, and the temperature, moisture, and ventilation of an ordinary stove; but are better grown by themselves, as in stoves they are often assigned positions unsuited to them. Given the same treatment as house-grown Cucumbers

they thrive well, or a brisk moist heat, and shade only to prevent scorching; the temperature in winter should be kept at 65°, *Nepenthes sanguinea* is one of the finest and rarest; *N. Veitchii*, *N. zeylanica rubra*, *N. Rafflesiana*, *N. Sedeni*, *N. Hookeriana*, *N. hybrida*, *N. Cheloni*, *N. intermedia*, *N. ampullaria vittata* major, *N. albo-marginata*, and *N. Courti* are the best. Fibrous peat, with a fourth of crocks or charcoal in pieces about the size of a hazel nut, about a sixth of silver sand, and a like proportion of chopped sphagnum, with good drainage, will grow them well. Spring is the proper time to pot, but if received now in very small pots a slight shift may be given now, suspending them near the glass, transferring to larger pots or baskets in the spring.

Lasiandra macrantha is one of the brightest purple-flowered of stove plants, but the plant is of straggling habit. Grown as a climber it is very fine. From the point of every shoot bunches of flowers are borne expanding successively for several weeks; for though the flowers last but a day their profusion and succession make up for their short duration. It does well in a cool stove. The dwarf variety, *floribunda*, is valuable for cutting in small pots.

Poinsettias should be placed in the stove, assigning them a light position with a temperature by artificial means of 65° to 60°, affording weak liquid manure liberally, and they will make a grand display. The weakest plants should be continued in a temperature of 55° at night, affording water only to preserve the lower leaves, for if overwatered the roots will perish and the bracts produced will be very poor. These plants will come in after the first batch, and though the heads may not be so large they are extremely useful for cutting, enduring much longer than those grown in more heat.

Euphorbia jacinthiflora should not be subjected to a lower temperature than 50°, better 55°, or the roots will perish, care being taken not to overwater, affording all the light practicable. *Monochaetums* also must not be kept too warm; 50° at night is, however, necessary, and in that they will flower for weeks, but in a higher temperature the flowers are of short duration. *Thysacanthus rutilans* requires a light position, and should have weak liquid manure. *Centropogon*, which must have plenty of light, and 55° min. temperature. *Sericographis Ghiesbreghtiana* must have all the light possible and a genial temperature, in which it will flower freely. *Plumbago coccinea superba* should have a portion of the plants placed in the coolest end of the stove with a view to a succession of bloom. Winter-flowering *Begonias* afford plenty of light, and feed with weak liquid manure. If any need repotting shift them into a size larger pot. Afford *Apheleas* positions near the glass; their fiery heads of bloom enliven a stove immensely. *Begonia manicata* keep rather dry in a temperature of 45°, returning the plants to the stove in about six weeks, when they will in due course afford a mass of pink blossoms of light appearance. *Ixoras* that have flowers yet to open must not be syringed overhead, or but seldom, or the flowers will drop without opening. *Allamandas*, *Bougainvilleas*, *Clerodendron Balfourianum*, and *Rondeletias* that have yet flowering parts in an advanced state should only have enough water to enable the flowers to open, which will not only secure the flowers for cutting but ripen the wood. *Dracenas* and *Palms* as yet in cool conservatories must be returned to the stove without delay, or they will if detained much longer lose their leaves when returned to warmth.

Stove Ferns are spoiled by too much heat, particularly is this the case during the winter season; 55° at night is ample by artificial means, which will necessitate less moisture and a lessened quantity at the roots, admitting air more freely. Dispense with shading, the light will improve the texture of the fronds.

TRADE CATALOGUES RECEIVED.

E. G. Henderson & Sons, Pine Apple Nursery, Maida Vale, London, W.—*Catalogue of Dutch Bulbs and other Flower Roots.*

Edmondson Brothers, 10, Dame Street, Dublin.—*Catalogue of Hyacinths and other Bulbs.*

William Rumsey, Joyning's Nurseries, Waltham Cross.—*Catalogue of Roses, Shrubs, Fruit Trees, &c.*

New Plant and Bulb Company, Colchester.—*List of Japanese and other Bulbs.*

James Yates, Royal Oak Mills, Stockport.—*Catalogue of Dutch and other Bulbs.*

Hogg & Robertson, 22, Mary Street, Dublin.—*Catalogue of Dutch and other Bulbs, Garden Requisites, &c.*

T. Carden, 3, Union Street, Leicester.—*Autumn List of Hyacinths and other Bulbs.*

W. Dobbie, 62, Preston Street, Faversham.—*List of Fuchsias and Geraniums.*

Robert Mack & Son, Catterick Bridge, Yorkshire.—*Catalogue of Select Roses.*

Samuel Yates, 16 and 18, Old Millgate, Manchester.—*Catalogue of Dutch and other Bulbs, List of Roses, &c.*

James Dickson & Sons, 108, Eastgate Street, Chester.—*Catalogue of Bulbous Flower Roots, &c.*

TO CORRESPONDENTS.

* * * All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

BOOKS (*Constant Reader*).—"British Ferns," by G. W. Johnson, by post 3s. 9d., and "Poultry Book for the Many," by post 7d., both published at this office.

"E. B." is desirous of obtaining a copy of the "Horticultural Directory for 1878," which is now out of print, for which he will pay full price. "E. B." should send his address.

BACK NUMBERS (*Seser*).—The back numbers you require can be supplied if you order them through your newsagent.

COCKSCOMB (*W. Craike*).—The head is a fine one, exceeding 2 feet across, and the colour is remarkably good. The comb, however, is irregular in outline, as those produced by fasciated stems frequently are.

ARRANGEMENT OF FLOWER BEDS (*F. M. D.*).—We should have the flower borders next the walk, so as to correspond with the border on the opposite side, in both cases having wide grass verges between the flowers and the walk, but the exact width can only be determined by the size of the lawn and the width of the flower border. Do not have the stand and Roses too high; 2 feet in height of clear Briar stem will be ample for the beds and their position.

VENTILATING GREENHOUSE (*W. T. Whalley Range*).—Slide ventilators fixed at the back of the house as you suggest will answer the required purpose, but more care is necessary in managing them during cold weather in early spring than in the case of ventilators in the roof.

DESTROYING THRIPS (*R. W. B.*).—All the leaves sent are much infested by thrips. The plants have been neglected—have probably been kept too dry, and have neither been syringed nor fumigated regularly. Frequent fumigations will destroy thrips, as also will a strong solution of soft soap and tobacco water, the plants being laid on their sides and syringed so that the insects, which are chiefly on the under sides of the leaves, may be reached by the solution; 2 ozs. of soft soap dissolved in a gallon of water, and half a pint of tobacco water added, will destroy thrips and will not injure the plants. Probably the insects are also preying on your Vines; if so you cannot expect to have good Grapes. Remove a portion of the surface soil from the border, just baring the roots, and replace with fresh loam, and topdress heavily with manure to induce roots near the surface, by which your Vines would be much benefited. Train the shoots thinly also, and keep the foliage clean.

PROPAGATING *ARALIA ELEGANTISSIMA* (—).—It is best grafted on *Aralia reticulata*, cuttings of which strike readily in about a month. They may be inserted at any time in bottom heat of about 85°, and top heat of 80°. Grafting may also be done at any time when the stocks are in free growth, keeping them in the same temperature as recommended for striking the cuttings. Both *A. Veitchii* and *A. elegantissima* are rather difficult to propagate by cuttings, and you had better not risk the loss of your plant by attempting that mode of propagation.

SELAGINELLAS IN THE POTS OF STOVE PLANTS (*Ivy*).—If the Selaginella is allowed to grow luxuriantly and permanently it will injure some stove plants, especially those intended for specimens, but is permissible in the pots of plants grown for table decorative purposes and plants generally that are only required in a small state. It is less injurious in the case of Orchids, but even then should be kept within reasonable bounds; it must not shade the pseudobulbs of the plants.

CHRYSANTHEMUMS (*F. P. W.*).—While the weather remains open your plants will be much benefited by remaining out of doors. We only place ours under glass on the appearance of frost at the time the flower buds are showing colour. Instead of allowing them to stand closely packed together we prefer to have them in single line along the side of a gravel walk. We choose such an exposed position in order to expedite the ripening of the wood, the want of which we think is the cause of your plants not being already in bud. We grow some hundreds, and all are now (September 23rd) disbudded, most of the buds being as large as peas. This is done by watching for the appearance of a terminal bud, around which are frequently three advancing buds or growths; these growths are removed, and the strength of the plant is thrown into the one flower bud that remains. If your plants have passed by that stage they will have made about three new growths on each branch, which will later on doubtless throw some very fine flowers, but in the majority of cases the flowers cannot be had as large and as full in the centre as if the centre bud which appeared between these growths had been left alone to perfect itself.

PLANTS FROM SAXONY (*A Seven-years Subscriber*).—If the plants are sent by post and the letter rate of postage is paid thereon the parcel will not be opened.

CACTUSES (*Idem*).—As a rule the plants are safe in minimum temperature of 40° during the winter, the soil being kept dry. In reply to your query No. 3 we advise you to write to Mr. Croucher, Sudbury House, Hammersmith, who will give you the desired information. We do not know of a book other than the one you name that is devoted to the culture of succulents.

PROPAGATING VIRGINIAN CREEPER (*S. H.*).—It is propagated by layers and cuttings; the latter mode would suit you as you require quantity. Take the ripe wood of the current year's growth, cut it into lengths of two joints, cutting transversely below the bottom eye, and insert firmly in rows about a foot apart with the cuttings 4 inches asunder, and so deep that the uppermost eye is only just clear of the soil. Sandy moderately rich soil is preferable, and a sheltered situation desirable.

HEATING GREENHOUSE (M. W.).—A stove is not a desirable mode of heating; the dry heat and the danger of the products of combustion escaping into the house are disadvantages often proving disastrous. Have a stove boiler fixed in a shed at the back of the house with a 3-inch flow and return pipe along one end and the front of the house. The boiler may be placed within the house, but there is a danger of an escape of smoke, &c., and dust consequent upon stoking. We cannot name any particular tradesman. Consult our advertising columns.

GRAPE CULTURE—LATE GRAPES (S. G. S.).—Thomson's "Treatise on the Cultivation of the Grape Vine." The best late Grapes are Lady Down's Seedling, Mrs. Pince, Black Alicante, Gros Guillaume (Barbarossa), West's St. Peter's, and Trebbiano.

PLANTS FOR DRAWING-ROOM DECORATION (Idem).—The most suitable are flowering plants having some scent, but not too powerful, interspersed with foliage plants. Forced plants are particularly acceptable; but you say nothing as to what are your means of production, consequently we are at a loss as to how to advise without giving the names of all plants that flower from October to March, which, with foliage plants, comprise half those in catalogues.

TRANSPLANTING ROSES BUDDED IN THE SUMMER (A Lover of Rose Shows).—The plants may be transplanted in November, planting them as deeply as they were before, not deeper, and they will start into growth very nearly as strongly as if they were allowed to remain in their present quarters. We prefer, however, to allow a season's growth to be made before transplanting to their permanent position.

MALT DUST.—"A Lover of Rose Shows" wishes to know if there is a malt kiln near London where he can obtain the "dust" that is recommended to be mixed with horse droppings to form a compost for dressing Roses, and how much a bushel he would have to pay for it.

TEA-SCENTED ROSES FOR WALL (Clericus).—It will not be necessary to have any ventilators for your glass projecting coping at the upper part of the wall, for those would frustrate the object of the glass projection. The lights need not be moveable. Besides Mâchael Niel, Safrano, Sombreuil, Niphotos, Belle Lyonnaise, Cheshunt Hybrid, and Souvenir d'Elise are suitable for your purpose.

STORING DAHLIA ROOTS (Idem).—We presume the plants were received by post and have been planted out. Take them up after the first frost, and after remaining a few days in a shed to dry, store them away in sand in a place safe from frost, but the cooler they are the better provided frost be excluded.

HEATING GREENHOUSE (O. G. R.).—The great objection to heating by a stove is the vapour given off, and the gases escaping not being favourable to plant life, while stoves heated by paraffin and other oils are generally expensive. Have a stove boiler, with two rows of 3-inch pipes along the front of the house, as advised for "M. W." in to-day's Journal. We have no experience of the boilers alluded to.

ABUTILON FLOWER BUDS FALLING OFF (C. N.).—It is a result of imperfect root-action, in most instances occasioned by the plants being root-bound or of a check given them by allowing them to become too dry. The remedy is to afford more liberal treatment—increased pot-room, or if that be undesirable, afford weak liquid manure. The plants should have a light airy position in a rather warm greenhouse if expected to flower in winter. We strike cuttings about June placed singly in 3-inch pots, shifting them into 6-inch pots in August, growing-on the plants in cold pits. The plants commence blooming in late September, affording a quantity of flowers through the winter in a temperature of 50° to 45°.

CACTUSES FLOWERING (Idem).—We presume they are Epiphyllums, now and onwards being their flowering season. They should be kept moist at the roots, but avoid overwatering them or the roots will perish.

ADIANTUMS (Idem).—It is usual for *A. cuneatum* and *A. fulvum* to lose a good portion of their fronds in winter when the plants are in a cool greenhouse. Keep them rather dry but not dust-dry, affording more water when they start into fresh growth, as they will do about March. In a stove temperature they are evergreen from fresh fronds being made keeping up the evergreen character, but the growth of such is poor as compared with plants that are afforded a season of rest.

MAKING ASPARAGUS BED (Old Subscriber).—The soil should be trenched 2½ to 3 feet deep, and manure be very liberally mixed in during the trenching. If the soil be light and open nothing more will be required, but if heavy it should have sand added and charred vegetable refuse, so as to bring it into a friable state. If very heavy take out the soil to the depth of 3 feet, rejecting all that is not in an ameliorated condition, which may not be more than the top spit, and mix with this an equal quantity of turfy light loam, vegetable soil or refuse at least half decayed, or leaf soil and well-decayed manure, the whole being thoroughly incorporated and a fifth part of sand added, and with this compost fill up the space intended to be planted a foot higher than the general ground level to allow for settling. Plant one or two-year-old plants in spring in beds 4 feet wide with 2 feet alleys between them, three rows to be in a bed and the plants 1 foot apart. If large heads are wanted plant in rows 3 feet apart, and the plants 18 inches asunder; or seed may be sown in April, thinning the plants to the above distances.

CROWN IMPERIALS NOT FLOWERING (Idem).—They are probably grown in a shady position, which will account for their not flowering, otherwise we should consider the plants had not attained sufficient strength. Without data we cannot advise.

DESTROYING "KECKS" (Idem).—No tap-rooted weeds can withstand the effects of sulphuric acid, not even "kecks." We apprehend the vitriol has not been applied in quantity proportionate to the size of the weeds, or not to their centres. Perhaps it is another generation or plants not previously acted upon that you are now troubled with. We never knew the vitriol fail, and know no other remedy but grubbing up the weeds.

PREPARING HOME-GROWN TOBACCO FOR FUMIGATION (A Young Gardener).—When the leaves have attained their full size and become of a yellow hue they are taken from the stalk, tied together in small bunches by the footstalks, hung in a dry airy room to dry, and left there until dry and crisp. The first damp weather after this the leaves will become soft, and they should be watched to ascertain when this occurs; then pack them in a box evenly with the butts or stalk-ends of the leaves all one way. They are then to be pressed moderately, and in a few days a slight fermentation will take place, when the bunches should be taken out and shaken to let the heat escape. When this has been done repack lightly. The leaves will not reheat, but it

is best to let them remain for a few days laid lightly in the box, and when all fermentation is over pack lightly in a barrel and keep in a dry place ready for use. As the leaves of British-grown Tobacco are not all mature at one time, they must be successively gathered as they ripen. The circumstance of the leaves not being all mature at one time has led to the adoption of another mode—viz., when the leaves have attained their full size pull the plants up, tie them two or three together, and hang them, root upwards, in a dry warm room, if with a temperature of 90° all the better. When dry sprinkle them with water, and then hang up again to dry. Allow them to become dry again, and then wet them again; dry afterwards, and let this wetting and drying be done thrice. When the leaves become dry, but not so as to break, strip them from the stalks and lay them in boxes evenly, and quite close and tight, pressing for that purpose, then keep in a dry room. This latter process gives the leaves a colour which they will not possess if treated according to the first plan. Leaves prepared in this way will be green, while those treated according to the first mode will be of a pale brown and be fit for smoking. Leaves prepared in both ways are alike useful for fumigating for green fly, thrips, &c., and equally as effective as foreign Tobacco. Previous to use the Tobacco should be chopped like hay and straw or made into rough shag.

DESCRIPTIONS OF PLUMS (C. W. M.).—Coe's Golden Drop.—Fruit very large, being generally about 2½ inches long and 2 inches in diameter, of an oval shape, with a short beak at the stalk, marked by a deep suture extending the whole length of the fruit; skin pale yellow, marked with a number of dark red spots; stalk about an inch long, stout, and attached without depression; flesh yellowish red, sugary, and delicious, adhering closely to the stone. Jefferson.—Fruit large, oval, narrowing a little towards the stalk, and marked with a very faint suture; skin greenish yellow, becoming of a rich golden yellow, flushed with red on the side next the sun, and dotted with red dots; stalk an inch long, thin, and inserted in a shallow cavity; flesh yellow, firm, and juicy, rich, sugary, and delicious, separating from the stone.

POTTING LILYUMS (Surrey Amateur).—Pot them immediately after the flower stalks become yellow, and instead of taking the bulbs entirely out of the soil, turn the plants out with the ball entire. Remove the surface soil down to the crown of the roots, and cut the stalk or stems off at that point. Next remove the drainage and any soil that comes away easily. Clean the pot inside and replace the drainage with an inch of the rougher parts of the compost over it, then a little compost, then the roots, working the soil carefully around them, and cover the crowns about an inch deep. If the work be done well the pot will be about three-parts full; the remaining space should be filled with compost when the shoots are sufficiently high for the purpose. Give a gentle watering after potting. We use a compost of two-thirds turfy loam a year old from decayed turves cut 3 inches thick, and one-third leaf soil or turfy sandy peat, with a free admixture of sand.

LAMP OIL FOR A SMALL GREENHOUSE (W. H. Summers).—Petroleum will suit your purpose.

NAMES OF FRUITS (Mr. Killick).—Court of Wick. (W. B.).—1, Courpendu-Plât; 2, Gravenstein. (R. C.).—Robinson's Pippin. We are doubtful if you can procure "our York" from the beginning unbound. (S. N.).—2, Barton's Freebearer; 5, Yorkshire Greening; 6, Alfriston; 9, Hollandbury; 10, Selwood's Reinette. Pear Baronne de Mello. (F. McLennan).—1, Hawthornden; 2, Cockpit; 3, Keswick Codlin; 4, Blenheim Pippin. (Croydon).—We are sorry to say we cannot assist you. You had better have some trees grafted from your present one. It is the surest way of securing the true variety. (W. H. W.).—Pears: 1, Bad specimen; 2, Beurré Capiaumont; 3, Calabasse; 5, Williams' Bon Chrétien. Apples: 1, Scarlet Nonpareil; 2, Hawthornden; 3, Sam Young. We never name more than six fruits. (W. Henry Ashwin).—1, Beurré d'Amaulis; 2, Duchesse d'Orléans.

NAMES OF PLANTS (Mrs. H.).—The larger-flowered Fuchsia is corallina, and the smaller is, we think, an inferior variety of it. The Oxalis is *O. Deppei*. (Mrs. Poole).—*Saponaria officinalis*. (J. W. S.).—*Balsamina hortensis*. (Southland).—*Pyrus intermedia*. (Young Botanist).—1, *Nolana prostrata*; 2, *Buddleia globosa*; 3, *Tamarix gallica*; 4, *Santolina Chamaecyparissus*. (Mrs. B. Brandon).—*Crataegus Crus-galli ovalifolia*, native of North America. (Ramalho).—*Adiantum amabile*. If you examine it carefully you will find that the indusium is connected with the margin of the pinna. (A. W. B.).—The numbers on your plants were displaced in transit. The herbaceous plant is *Convolvulus mauritanicus*. The Maidenhair is *Adiantum trapeziforme*. The other Fern we cannot determine; it has no spores. (Warwick Subscriber).—1, *Alonsoa incisifolia*; 2 has no flowers; 3, *Artemisia vulgaris*. (Manchester).—1, *Rivinia humilis*; 2, *Aucuba japonica*; var.; 3, *Tradescantia zebrina*; 4 is a *Platyloma*, and 5 a *Pteris*; but as the fronds have no spores we cannot determine the species. (W. H. F. B.).—No. 1, *Mirabilis Jalapa*, belongs to *Pentandria Monogynia* of Linnaeus; No. 4, *Geum rivale*, belongs to *Icosandria Polygynia*.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

THE CULTIVATION OF WHEAT.

(Continued from page 233.)

WE will now refer to the cultivation of wheat upon loamy soils. As these are various we must name those which require at present particular notice, such as sandy loam on brick earth, hazel loam on gravel, grey loam on chalk, and the dark or peaty loams of the fen districts, as well as some red loams of the western counties. Assuming that upon nearly all these soils the land is dry enough for wheat, we consider that the natural power and fertility of much of the above-named loams will justify a departure from the Norfolk or four-course rotation, especially when the land is highly manured, in order that a better return may be made by the sale of crops and stock than the simple four-course usually affords. These soils are for the most part subject to couch or running

grass, which will necessitate something approaching the four-course system, in order that the land may be cleaned by a fallow crop such as mangold and other roots. In this case a considerable portion of the land may be sown with wheat which in the ordinary four-course would be sown with Lent corn, either barley or oats. According to our experience the yield of corn does not so much depend upon the distance of time between the crops of wheat as it does upon judicious management and preparation of the land. We have found with but few exceptions that when the seed has been put in under favourable circumstances, and the ground good enough to produce a full crop of straw, that the produce of corn depends upon the season. In hot dry summers we usually obtain a good yield, and in a cold wet season the reverse. We have, however, noticed sometimes, that although the grain has been abundant the weight of it has been deficient perhaps about 2 lbs. per bushel. In some cases we have known the same field of good hazel loam cultivated or rather cropped with potatoes and wheat alternately for a number of years, and that whenever the season was favourable large crops of wheat—as much as fifty-two bushels per acre, have been grown. When we have cropped the land thus the potatoes received a liberal dressing of guano, and the same of yard or town dung was applied to the wheat crop.

We must now allude to a mode of cropping called the three-course rotation, and when the land is clear it is adopted with great advantage, particularly where the soil is a little too flat and heavy for the winter folding of sheep whilst eating roots—viz., first, wheat out of clover lea; second, barley or oats according to climate; third, clover mown twice for hay or seed. This plan, by judicious cultivation, will pay more rent and leave more profit than the four-course system. But although this plan may be carried out on the home farm, yet on many farms the occupier would be debarred by the conditions of his lease. It may be said that this system will keep but little stock; but upon the home farm where there is a good portion of meadow or park lands these will keep the stock principally in the summer months, and upon a portion of the clover lain good roots may be grown after one cutting of clover, and good stubble turnips after the wheat, where the climate is favourable.

We will next speak of the cultivation for wheat after clover. If any portion is broken up for roots the cultivation for it will be referred to further on under the head of Light Land Culture. Upon good loamy land the early ploughing and pressing is of great consequence, because in these soils, which often vary in the same field, it is very necessary that the land be allowed to lie and become mellow before sowing, and at the same time it becomes consolidated, so essential to the well-doing of the wheat plant. It is on the lea that the dung should be laid out and ploughed in. Let us, however, guard against the couch and water grass as much as possible, and if it is found on the clover lea by no means to attempt a late or what is commonly termed a bastard fallow, this being the worst preparation for wheat on these soils which we know of. We prefer to scarify very shallow and clear away the grass, and then to lay out manure, plough, and press the land; this will give all the advantages of the clover lea without making the land hollow and unkind for wheat. Upon these soils the roots of clover make a capital manure for wheat, and it is better that the clover be cut twice or even cut for seed because of the great increase of the substance of the roots of clover. We have repeatedly seen the difference in the wheat crop, where two cuttings as compared with once cut and then fed off with sheep, the former proving the best preparation for wheat, although the sheep may be folded upon the land whilst eating off the clover.

The time of sowing wheat upon these soils, although it may have been early ploughed, should be deferred until about the middle of the month of October; and the quantity of seed should not be less than two bushels and a half per acre, as the wireworms are more likely to attack the plant than upon a fallow preparation. It is also important that the wheat should be prepared and steeped to prevent smut. It is not sufficient that the seed sample gives no evidence of smut, because the smut balls may have passed away in the act of winnowing, threshing, &c., but the ears often contain smut balls and sound corn also. The sound corns are, however, sure to produce smut the following season unless some method is adopted to kill the disease in the corn. Some use vitriol (sulphate of copper) commonly called bluestone vitriol, but the best way and least trouble is to use a composition sold for the purpose and called Down's Farmer's Friend. Upon loamy soils, if not much given to weeds, the wheat may be drilled at 7 inches; otherwise it may be drilled at 9 inches between the rows, so that it may be hand or horse-hoed in the spring. We, however, seldom find that wheat sown out of clover lea is infested with annual weeds.

The sorts of wheat selected for seed should be adapted to the climate, white varieties being good for the eastern and southern counties, and red sorts for the midland and western districts. When the land is highly manured and a heavy crop is expected any short-strawed variety is best, the Rough-chaff Essex being the best, quantity and quality considered. Schooley's Square Head is also a good sort. These, together with Golden Drop and Nursery, also with some other sorts having local name and origin,

when selected by Pedigree, make up a sufficient choice for growth upon the home farm. The seed, however, should always be grown upon an inferior soil, and the judgment of the farm manager will always be required to take notice of the sorts which best suit the soil.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour still consists of ploughing and working the land for rye, winter vetches, &c. Upon all those farms where the land is at all foul with couch grass autumn cultivation should be carried on upon the land intended for roots next year by scarifying or rafter-ploughing, and upon all dry loamy, or light gravel and sandy soils, this work may be continued in fine weather until the commencement of the autumn rains, and then it will be time to begin laying out manure, and preparing by ploughing and pressing the land intended for wheat; the latter work, however, may also be done at intervals of weather unfavourable to autumn tillage of the stubbles. Upon farms in certain districts it is necessary in the interest both of landlord and tenant, and especially on the home farm, that any land requiring chalk should have an application immediately it is ascertained to be requisite. There are many kinds of weeds the growth and prevalence of which indicate the absence of chalk more or less. The autumn part of the year whilst the roads are firm is the best time for carting chalk. The horses belonging to the home farm, where the horse power is judiciously apportioned, will, however, not be able to accomplish such extra work as carting chalk. We have on various estates with which we have been connected found it best to hire for this work, which is not only very laborious for the men and horses, but is very wearing to the harness and carts employed. We have found it in consequence answer a good purpose to arrange with the hirecarters of the district to deliver the chalk on the farm at any time during the summer, to be made up into heap and subject to measure. A cube yard weighs from 18 cwt. to 1 ton. The cost of cartage per cube yard will vary according to the distance from the pit; but the hirecarters will accept a contract on easier terms if they have early notice of the quantities required, and are allowed to work at it so as to fill up any leisure time they may have in their hiring business. The horses employed on the farm may then lay out the chalk from heap when most convenient, from 18 to 20 tons per acre being a sufficient quantity upon soils in general. The odd horse will have full employment in various ways. It will be necessary to see that the rick yard is made clean and tidy by the removal of all litter after thatching and trimming the ricks; this will afford some bedding for the pigsties. The late-sown vetches and oats or the late-sown trifolium will now be very valuable for the horses, the cattle, and pigs, and will be required for use daily, and should be brought to the homestead by the odd horse or horses.

Hand Labour will now be employed in various ways—tending the threshing machine, making up and thatching the straw and fodder ricks, and spreading dung on the clover leas. The home farm manager will do well now to look at all the fences and have them properly trimmed, and the ditches cut out free from the coarse grasses, &c., which grow upon the sides. Particularly examine ditches and watercourses where it is known that tile drains have their outlets, so that the water may have no obstruction when the early autumn rains begin. As fast as the corn is thrashed have the ricks of straw and fodder properly stacked, and the roofs of the stacks raked down hard with the thatcher's rake. In the case of wheat straw for general use the roofs will then only require thatching halfway down; but it is different with barley or oat straw, or pea haulm required for fodder, for these should be put together in good shape in the rick, and be as carefully thatched as a rick of hay. Straw is now so dear that the same care in ricking and thatching should be observed with all that portion intended for sale. The mangold crops are in some cases very foul, and as fast as the last hoeing is done women should pick up the couch grass and weeds. The same observation will apply perhaps to Swedish and common turnips. The hoes have killed but few weeds this year on account of continuous rains. When cabbages are required for the early spring they should now be set out, and if the field is much exposed it is well to have the land stretched or baulked at 2 feet apart, and set the plants in the furrow between the stretches, guano being strewn along by hand. In case of snow in the winter the plants will then be covered, which will protect them against depredation by larks, wood pigeons, game, &c., and being in the furrow, if the soil is dry, will do well and be sheltered to some extent from cold winds, and in the spring the plants will be well healed up in the act of interculture. This is now a good time to purchase a stock of breeding ewes, and particularly in the home counties, within sixty or seventy miles of the metropolis, where the horned Dorset ewes are kept for making early lambs for the metropolitan market, some of which will be required at Christmas. These ewes are brought in large numbers to the fairs held at Weyhill and Apple-shaw in Hampshire, buyers from various counties attending as purchasers. These ewes are very pretty and ornamental stock on the park lands from the middle of October until the middle of

November, at which time they have many young lambs with them. This kind of sheep usually give a large number of twin lambs, and they not only furnish one of the prettiest objects on the park lands, but are very profitable upon the home farm if judiciously managed. The shepherds must now be vigilant, and all those sheep which may have been recently shorn should now be dipped or leared with powder to secure them against the attack of the blow flies, if it has not already been done, for the hot close weather lately prevailing has been much in favour of the fly damaging the sheeps' fleece. The purchasing of sheep, both of ewes and dry sheep for winter keeping, will still be going on. We recommend where it can be done to purchase of the breeder, so that the sheep can travel direct to the place where they are required, in order to avoid the lameness which they so often pick up at the fairs. The ewes which have the rams running with them still require attention in the daily change of food, so that they may be induced to bring their lambs well together. Dairy cows should now be purchased when a good supply of milk is required during the winter months, but we do not like to purchase them in the metropolitan market. When we require a nice lot of the Yorkshire Shorthorns we prefer giving a commission to those engaged in supplying the London dairies with the best stock, instead of taking animals direct from the metropolitan market, because whilst there the animals often take by infection foot and mouth disease, and sometimes pleura. In case of ordering them of a dealer they are sent by railway to any part of the country direct, in which case they usually arrive healthy and in fine condition; for be it remembered that many of the finest cows on sale in the kingdom are obtainable by the dealers who supply the London market and the suburban dairies. When it is desired to rear the calves the dealer will send you cows with heifer calves if the order is given in that way. We know cows frequently obtained in that way which are very beautiful and also great milkers, and have given much satisfaction upon the pasture farms where they have been kept. The stock of horned cattle for winter feeding and fattening upon roots in the stalls or boxes should also be purchased now. If Hereford steers are wanted, Hereford October fair is a good one for purchasers; if shorthorned cattle are required, there are many fairs in the midland counties where the best blood can be obtained. Many Irish yearlings and calves are now sent over; but although they are much better than they used to be, still the buyer should select the best animals out of a herd and pay more money for them, as the best are always the cheapest. These will do very well for wintering as stock animals, but for fattening in the boxes the two-years-off cattle are the best, and we have often picked up half-fat bullocks at markets which have paid well for winter feeding.

VARIETIES.

THE following is from the *Oxford Times*—"The members of our Poultry and Pigeon Society have reason to be disappointed with the result of the special meeting of the Town Council, held last Thursday morning, to receive the memorial of 1500 ratepayers to the Mayor and Corporation requesting a reconsideration of their refusal to grant the use of the Town Hall, as well as the use of the Corn Exchange and Yard already granted, for the annual Show. The cause of the disappointment seems to be attributed to four absent councillors, three of whom signed the memorial and promised to attend the meeting to support it with their votes, and the other, though refusing his signature, promised to vote for it. Had these gentlemen redeemed their promises there must have been a majority instead of a minority of two in favour of the memorial. Hence the bitterness of the disappointment. The Show Committee argue with much reason, that in order to maintain the high standard and extent of the Society's annual exhibition they cannot reduce their schedule to the proportions necessary for the accommodation afforded without the Town Hall. Last year the Corn Exchange was crowded to its utmost capacity with six hundred fowl pens, two-thirds of the Town Hall yard were occupied with two hundred large pens of Geese and Ducks, and the Town Hall itself accommodated 1100 pens of Pigeons, &c., many of them birds of too great a value to be exposed to the inclemency of the Town Hall yard. Alderman Carr contends that there is a greater space in the yard than in the Hall. However that may be, one thing is certain, that the quality of the accommodation must be in favour of the Hall." Owing to the strong feeling that has been evinced by the inhabitants, the Town Council has since reversed the decision refusing the use of the Town Hall to the Poultry and Pigeon Show Committee by a large majority.

A SURREY COLUMBARIAN SOCIETY is in process of formation; a preliminary meeting of fanciers was held at Guildford on the 18th inst. to consider the matter, and it is intended to hold a public meeting on October 10th for the adoption of a code of rules.

MR. F. JONES of Greddington, near Kettering, writes—"I have a hen which has been laying since the 28th of January, never missing above one day and that occasionally. She has laid to-day

her two-hundredth egg, including four large ones the size of a Duck's. As I think this very remarkable, I should feel obliged if you would state the above in the *Journal of Horticulture*."

THE Waterford Poultry Show was held in connection with the Farming Society on the 12th inst., when the following prizes were awarded:—

COCHINS.—1, Miss M. Barron. 2, C. N. Bolton. DORRINGS.—1, Miss M. Barron. 2, C. N. Bolton. HAMBURGS.—1 and 2, Lady Lloyd. BRAHMAS.—1, R. A. Chearnley. 2, Miss M. Barron. ANY BREED.—1, Miss M. Barron. 2, R. A. Chearnley. DUCKS.—*Aylesbury*.—Prize, Miss M. Barron. *Rouen*.—1, Miss M. Barron. 2, C. N. Bolton. SELLING CLASS.—1 and 2, Miss M. Barron. ANY PURE BREED.—1, Miss M. Barron. 2, C. N. Bolton. *etc.*, Lady Lloyd, C. N. Bolton. GESE.—1, T. Kennedy. 2, J. H. Jones. TURKEYS.—1, J. H. Jones. 2, C. N. Bolton.

ACREAGE REQUIRED FOR A COW.—An American paper writes as follows upon this subject:—"This question depends for an answer so much on the circumstances of the soil as not to admit of a very definite answer. In a dairy competition in Jefferson county, N.Y., in 1857, the first-prize dairy, of sixteen cows, was kept on thirty acres of land; the second premium dairy, of eighteen cows, on sixty acres; the third dairy, of thirteen cows, on thirty acres; the fourth, of twenty-nine cows, on fifty-five acres; the fifth, of twenty-eight cows, on ninety acres. Mr. Schull, of Little Falls, N.Y., estimates that the land in pasture and hay requisite for the support of a cow is three acres; and this is the estimate of Mr. Carrington for moderately good dairy farms in England. In Belgium ten acres of land support two cows, one heifer, and one yearling or calf; but when the calves are sold off young, and cows in full milk are only kept, the proportion is two cows to seven and one-half acres. Colman estimates three acres of pasture as requisite for a cow in Berkshire County, Mass., while in some towns two acres of pasture are sufficient. Mr. Farrington, in the report of the American Dairyman's Association, thinks that on the average four acres are required per cow for summer and winter keep; while Mr. X. A. Willard thinks that in Herkimer county, N.Y., one and one-half to two acres of pasture per cow will answer, and in some exceptional cases one acre."

ACCOUNTS received from all parts of Ireland represent the harvest as a good one, and generally well secured. The yield of the cereal crops in the northern provinces is a fair average, and although in some parts of Leinster there is a lighter wheat and barley crop in the better corn-growing districts than was anticipated, it is much above the result of last year. The green crops are exceptionally good, and no further grave complaints are heard as to the potatoes. There never has been a finer hay harvest. For cattle there will be ample winter feeding, and the number and value of stock will consequently increase. A month's fine weather will be of great advantage to the country. The break in the weather a few days ago appears to have been but temporary, and no great mischief can be traced to it. The health of Irish cattle is much improved, and the demands upon the public purse for animals slaughtered have greatly declined.

COMB FOUNDATIONS.—"A. E. C." writes:—"Having seen in the *Journal of Horticulture* for September 5th an article from Mr. Arthur Todd, Algeria, in which he mentions that the American comb foundation can be obtained at 2s. per lb., I shall be much obliged if any of your correspondents can tell me where I could obtain the foundation at that price, or if anyone who is getting it from America would let me join them for a small quantity."

A WRITER in an Australian paper states that in many districts the leaves of the celery are highly esteemed as food for milch cows, and are often preferred to red clover. The cows are said to eat them most greedily, and to yield on this food a far sweeter and richer milk than on any other. Sometimes the leaves are cut up small, scalded with hot water, and given as a mash mixed with bran, and sometimes they are fed whole in their natural state along with the other ordinary food.

APIARIAN JOTTINGS.

It would be tiresome to go through the various operations among my bees which have taken place this autumn. Suffice it to say that without plundering to the full, as I had intended, every stock in my apiary, some of which circumstances have obliged me to leave untouched, I have harvested over a hundred-weight of honey of excellent quality, with which I am well content. This is very good for our poor country, with its limited supply of apple and bean blossoms and its one staple of clover honey, exposed as it is to the blast of every wind, which has free liberty of range in a thinly planted plain.

I must, however, say a few words relative to the Woodbury-Phillips bar-framed hive, into which I put a moderate-sized swarm on the 13th of June. On my return home in the middle of August I found thirteen out of the sixteen frames occupied with comb, many of them weighty with honey and brood. We took out most of the frames, cut away several pounds of honey-comb, and re-arranged the hive, correcting irregularities in the comb. This is now a very strong stock, with an excellent first-cross queen hatched last year. Before winter it will have a careful overhaul previous to its contraction to eight bar frames. The

empty spaces right and left of the contracted centre will be filled with shavings after the dummy slides have been slipped into their grooves.

Next year will afford the opportunity of fully testing this hive. As it is, I am so well pleased with it that I shall construct two more this winter on the same principle and of the same size. And to insure as far as possible its success as a non-swarming hive I purpose to construct a nadir hive to go under the floorboard, thus affording the bees all possible space above (by super) and below, as well as on the two wings of their central breeding home. The floorboard will be perforated with long and narrow slits, so narrow as to exclude both queen and drones. It will be in use during the summer months only, being replaced by an ordinary floorboard the greater part of the year. Before quitting the subject of this hive I must express a hope that Mr. Phillips will kindly tell me whether he is as pleased with his hive and has been as successful with it as he was last year. Perhaps, too, some other of your apiarian readers has made trial of it; if so, we should like to know how it has fared with him.

Talking of strong hives, here is everything calculated to promote strength. Has Mr. Pettigrew anything to say against it, barring his dislike of bar-framed hives? Large and roomy, with powers of expansion and contraction integral to the hive itself, and super or nadir space above and below, affording space for *ad libitum* management, whether on the swarming or non-swarming principle, methinks this hive meets all needs and embodies the perfection of a bee domicile. There is, of course, the one crucial difference between straw and wood; but the experience of forty years has convinced me that bees thrive as well in one as in the other.—B. & W.

THE STEWARTON SYSTEM.

SOME remarks of Mr. Pettigrew on pages 215 and 216 call for comment. The Stewarton hive has been adopted in Ayrshire for a much longer period than twenty years, having been in operation there since 1819, or nearly seventy years. From the beauty of the octagon supers exhibited last month at the Caledonian Apiarian Society's Exhibition at Dumfries, and this month at their Glasgow Show, we must have better authority that the Ayrshire fraternity have abandoned their pet hive and been converted into skepists.

That straw hives "have been refused admission to a Crystal Palace Bee Show," is to me new and somewhat startling. It is to be hoped the Hon. Sec. of the British Bee-keeper's Association may do something to remove this blot from their escutcheon.

Straw skeps, big as well as little, I readily grant never will cease out of the land as long as bee-keepers are ignorant of better; but my stipulation was "enlightened apiarians." With those the day of skeps, like that of the monster super, is over. These last, 4 inches deep, contain fully 20 lbs. while the 3½ octagon super which is abundantly large for home use or for the market, contains 15 lbs. Some of my Stewarton colonies are made to carry for variety, tier upon tier, little sectionals at times. Whatever description of hive is employed, the advanced bee-master to have his bees thoroughly in command must have their combs moveable, and it cannot be called in question that from the super or separate compartmental arrangement the purest and finest honeycomb is obtained free from all pollen, brood, or other impurity, and in the north, as I have already abundantly proved, sells, as it deserves, at a proportionally higher rate. The consumers of Wrexham may have no choice, but must purchase it as they can get it run into jars.

So far as reports have yet gone the season has been more favourable north than south, hence Mr. Pettigrew quotes Mr. Briscoe's smaller harvest of 56 lbs., and ignores the Renfrewshire parish clergyman's of 92½ and 88 lbs. super honey from a single hive; and in his comparison of my good harvest of 1868 it must be borne in mind that it was almost exclusively pure flower honey in super and nett weight, whereas what he pits against it was gross weight of a straw hive 328 lbs. including a huge skep well stored with thick broodcombs, brood pollen, and bees, and may we add board to boot? as part of the gross, and in Lanarkshire with vast tracks of heath to continue the season. Had my colony been transferred thither on the close of the flower honey harvest what a very different result might have been obtained. Fair comparisons, hives, bees, or systems of management can only be obtained from their being placed side by side in one and the same district.

Three weeks ago, in company with a keen apiarian, I paid a visit to a friend who possessed a valuable stock of bees, all in boxes excepting two large eked straw hives stocked by numerous odd swarms. When his boxes became exhausted in summer he was desirous to be put in possession of their store, and I cheerfully offered to lend a helping hand. After moving them from the stance we had but few of the bees driven, when the Italian section of the apiary were down upon us robbing as well as stinging badly, causing us to shift camp again and again; but there was no eluding them. We failed to see her majesty ascend and were forced to break up the skep to find her. Drawing the cross-sticks caused much breakage and more thieving, and though a med with

a couple of good honey knives there was no such thing as removing the deep combs entire. Our fingers and thumbs would sink into the warm soft pulpy mass. One basin after another of cold water was brought to clean and cool our hands, but the thick weighty cakes would give way, while with honey-dragged feathers we swept the poor clogged bees from the plates. We pitted the honey-smear brood, and still more the poor half-drowned queen fished out of a pool of honey in a corner of the crown. We three, accustomed to find her majesty at pleasure on frames and reaping large harvests of super honey without soiling a finger, then sweltering in the honied mess, were tickled by our host putting the question, Does Mr. Pettigrew really style this sort of thing advanced bee-keeping? We fixed the soft broodcombs of both skeps as best we could into frames of Stewartons, then introduced the respective queens and workers in inaugurating a new and better state of things.—A RENFREWSHIRE BEE-KEEPER.

OUR LETTER BOX.

DYING DURING TRANSIT (F. P. E.).—A bird or animal booked, and then in perfect health, dying during transit is a loss to the purchaser, unless it was not sent by the conveyance he directed it to be sent by.

DYING FEATHERS (A. Z.).—White feathers can be bleached, but we know of no mode by which coloured feathers can be rendered white.

BOOKS (E. C. H.).—Graham's "Domestic Medicine" is preferable.

REMARKS.

- 18th.—Wet and windy morning; fine and sunny afterwards; evening.
 19th.—Very fine bright morning, shower at 0.10 P.M.; fine and bright afterwards; starlight evening.
 20th.—Bright sunny morning; cloudy in middle of day, shower at 2.30 P.M.; fine afternoon; bright starlight night.
 21st.—Fine autumnal day; misty evening.
 22nd.—Misty morning, dull and cloudy all day, slight shower at 0.40 P.M.; wet evening.
 23rd.—Fine pleasant day; bright starlight night.
 24th.—Foggy in early morning, bright and sunny from 10 A.M. till 3 P.M.; fair but dull afterwards, and cool.

Although the prevalent wind has been westerly the temperature has fallen considerably, and one or two mornings have been almost frosty.—G. J. SYMONS.

COVENT GARDEN MARKET.—SEPTEMBER 25.

TRADE is very quiet, Pears being the only fruit in good demand, the crops on the Continent being short and consisting only of Duchesse d'Angoulême. Kent Cobs are lower.

From observations taken near London during forty-three years, the average day temperature of the week is 69.3°; and its night temperature 42.8°.

MIXED BORDERS FOR AUTUMN.

BESIDES bedding plants and hardy perennials, there is a host of beautiful flowers which ought to find a place in every garden with any pretension to completeness. They may not do for massing or making a great show, but some of them are sweet, others are pretty, some are useful for cutting for the decoration of rooms, and all are interesting in one way or another. The mixed border is the place for all such as will not fit in anywhere else. Almost anything in the shape of flowers, excepting perhaps scarlet Geraniums, will do there, and a most attractive mixture it is possible to make it if a little forethought is employed in the arrangement. I have such a border situate near the herbaceous borders, in fact temporarily filling the space intended for perennial plants as the collection increases, and I was rather afraid at one time that the temporary plants would prove more attractive than their more permanent neighbours. As a whole they certainly were the most showy, the sweetest, the best filled up, and afforded the greatest quantity of cut flowers; but on longer acquaintance I find there is not so much individuality in the plants, they lack variety compared with the perennials, and the first slight frost totally spoils them; nevertheless they have been extremely useful, and I think while the demand for large supplies of cut flowers lasts, and contemporaneously with it the fashion for bedding-out, which affords nothing to cut, we cannot do better than stick to the mixed border.

The background here is shrubs, as I think it always ought to be; then come Dahlias, two rows. The best varieties I have in a decorative point of view are Criterion, Lord Derby, Andrew Dodds, Chairman, Prince of Prussia, and James Cocker from 5 to 5½ feet high; Toison d'Or, Lady Dunmore, Sir Greville Smythe, Queen Mab, Sarah Maria, Bird of Passage, Lady Gladys Herbert, and Charles Backhouse, 4 to 4½ feet; Flag of Truce, Aristides, and Crystal Palace Scarlet are a foot less. I ought to have the small-flowered Dahlias called Liliputian or Bouquet varieties, as they are more useful for cutting than the large flowers, and I should be glad if someone who cultivates them would name the best half dozen.

Next to the Dahlias are *Convolvulus minor*, *Calliopsis tinctoria* and *C. atro-sanguinea*, sown in May in patches where they are to remain—the last two showy annuals are excellent for cutting; *Delphinium formosum* and several other varieties sown indoors in February this year. Treated thus they do not come so large as when treated like biennials, but they are very good and flower late in the season. *Chrysanthemum carinatum* and other annual varieties sown with Asters and treated in the same way are very fine; so is also *Chrysanthemum frutescens* from cuttings. I am trying some of the early-flowering varieties of *Chrysanthemum indicum*; some of them have done very well, notably Chromatella, Golden Button, Scarlet Gem, Adrastus, White summer Jardin des Plantes, Yellow summer Jardin des Plantes, Delphine, Cartouche, and Illustration. The Chrys-

anthemums named have all been in full flower some time, some of them as early as July, while others which I do not name have not yet shown their colours. Some of them seem just a little delicate, having lost many of their leaves; this may be the effect of rapid propagation in heat, but if we can keep this class of plants healthy they will prove real gardener's friends, as they will bridge over the time between the first autumn frosts and the ordinary *Chrysanthemum* season. *Gladioli* also come in this row, and there is none more useful than *Brenchleyensis*. Herbaceous *Phloxes*, although amongst the hardest of plants, should be here too, and be grown annually from cuttings struck indoors in March. Old-established plants, or such as are propagated by division of the roots, will bear no comparison with spring-struck cuttings. I selected the following names from those grown in the trial beds at Chiswick last year:—*Venus*, Mrs. K. Howitt, Princess Louise, Lothair, Coccinea, Dr. Balfour, Charles Rouillard, Figaro, Menotti, and Chatiment. This row has already a great variety in it, and yet there are the herbaceous *Lobelias* and *Salvia patens*, both too good to leave out; the former should be kept in a cold frame during winter and have the roots divided in spring; the *Salvia* should be kept like Dahlias and propagated in the same way from cuttings.

For the fourth row we have also a rich array of candidates. The better sorts of *Pentstemons* are very beautiful. Cuttings struck late in autumn and kept where they can be covered from severe frost are the best. Half a dozen good sorts are *Delicata minor*, *Rose Perfection*, *J. Decaisne*, *George Sand*, *Stanstead Rival*, and *W. E. Gumbleton*. Then we have *Marvel of Peru*, very sweet and very pretty. The roots of this should be taken up in autumn and kept in dry soil; also *Commelina cœlestis* and *C. alba*, which should be treated in the same way as the *Marvel of Peru*. The blue *Commelina* is without doubt the prettiest blue flower in cultivation; *Salvia patens* is dull beside it, and *Delphinium* is not blue at all in comparison; its only drawback is that it closes too soon in the afternoon, but then it seems to come out fresher and more beautiful every morning till it exhausts itself in seed-bearing or the frost touches it. *Zinnias*, *Victoria* and other tall-growing Asters come in this line, also *Antirrhinum*s grown from seed in the spring, and *Agapanthus*es and *Hydrangeas* potted late in autumn and kept in a cold place.

Now we have for the front line *Tigridia pavonia* and *T. conchiflora*; these require the roots to be taken up in autumn and kept in dry soil. *Linum grandiflorum* to be sown in patches in spring where it is to stand. *Dianthus Heddwigi* in variety, *D. laciniatus* in variety, *Intermediate Stocks*, dwarf *Chrysanthemum*-flowered Asters, *Tuberous Begonias*, scented Geraniums, scented *Verbenas*, and others too numerous to mention.

I have written of the plants here as being in lines for the sake of arranging them according to stature; but as a matter of fact there are none of them in lines excepting the Dahlias. The labels were arranged in lines early in spring, and then some of them in each line were shifted a little one way or the other to better suit the estimated heights and habits of the individual plants and to introduce

a little irregularity, which is more pleasing than a number of straight lines.

It will be observed that all the plants I have named are only summer and autumn occupants. I think it very undesirable to mix these plants with hardy perennials, as the latter, if well selected, are quite able to stand on their own merits; but if half-hardy plants are mixed with them there is certain to be an endeavour to fill up every little space, and in the end, owing to the quick growth of the latter, some of the more delicate perennials are certain to be overshadowed and probably lost.—WILLIAM TAYLOR.

THE ROSE ELECTION.—No. 2.

IN giving the first instalment of the voting papers I propose commencing with the lists of the amateurs, then the nurserymen, leaving those voting in the seventy-two varieties for the last. As regards the poll itself there are some additional points of interest. Nothing, perhaps, is more remarkable than the position reached by several of the newer varieties that promised well last year, especially Mons. E. Y. Teas, Duchesse de Vallombrosa, and Star of Waltham, the former rising from No. 35 last year to No. 24 this, the lady making a still greater jump from 54 to 18, whilst the Star shines out brightly at 30 instead of 47. Should this position of the Duchesse be maintained she will prove a great acquisition. But it may be asked, Have we not had an exceptional fortnight at the time Roses were at their best? I never myself bloomed Duchess of Edinburgh, H.P., out of doors before, so that she asked me to look at and admire her again; and after trying in vain Mons. Noman for a number of years without once seeing him even respectably attired I discarded the whole lot, giving the last plant to our cottage hospital. The Lady Superintendent is a dear lover of the queen of flowers. I happened to be there during that Rose week, and knowing almost the position and name of every Rose there I was greatly surprised to see a plant with eight or ten beautiful blooms on it. "Why!" I remarked, "what have you there?" "Oh, I don't know; one you sent here a couple of years ago without any name." And I discovered it was Mons. Noman, and several of the blooms on it were truly beautiful.

It must be confessed that the Teas do not figure very well. If by courtesy we consider Maréchal Niel one, that Rose is placed very low on the general poll—No. 8; neither is its position much improved in the seventy-two, where it is only saved from being very low down by a fourth-class vote. Then No. 28 comes Catherine Mermet; 37, Souvenir d'Elise; 38-9, Souvenir d'un Ami; 43, Marie Van Houtte; 44-5, Devoniensis; 58, Niphetos; 59, Gloire de Dijon, its exact position last year; 65-6, Belle Lyonnaise—nine Roses out of seventy-two varieties; and in the seventy-two election the number is still only nine. The fact is, that beautiful as they undoubtedly are, they have not the wear and tear constitution about them which most amateur growers require when they have not unlimited means at their disposal. Some persons are enthusiastic about Tea Roses, and when in their grandeur they are truly the most beautiful flowers; but how rarely are they thus seen, and how many are the failures for the one brilliant success! This, it seems to me, lowers their value. Taken as a whole, the Tea element is lower in position this year than last on the general poll. In some respects in the seventy-two the position improves, notably in Niphetos, which becomes 35 instead of 58; and it is natural that those who have a large number of plants of each variety may have the peerless blooms more frequently, and as a result their opinion of the variety is considerably enhanced. Grown under glass in the way advocated by Mr. W. Taylor in our Journal the blooms of the Tea are second to no Hybrid Perpetual, and need no artificial support to enable them to support the scrutiny of a judge, as do too many of the representatives of the class at the present day. But in how many amateur establishments are there to be found the appliances necessary for such results? and without them in exposed situations with ungenial soil the Teas are literally nowhere. I hope the day will never come when a Rose, even if inferior, is to score a point just because it is a Tea. I agree with the Rev. C. P. Peach in his letter to me when he remarks, "Let Teas stand on their own merits. If good they add to the beauty of the stand and increase its merits; if small and weak and tied up to sticks they only spoil it."

It must be remarked that this year Marie Baumann has achieved a grand success in both the elections of forty-eight and seventy-two varieties. It is the only Rose that was named

by every elector in the first twelve. I do not dispute her right for a moment. I certainly should place her at the head of all Roses for the exhibition stand, though I would like to see the stalk of the flower a shade stronger. Marie Baumann has retained her last year's position. Many electors testify to her being the best Rose, and several other Roses have at any rate maintained theirs. Madame Victor Verdier, No. 11; Camille Bernardin, No. 26; Abel Grand, No. 50; Gloire de Dijon, No. 59, with Marie Baumann at the head, occupy exactly the same position as last year.—JOSEPH HINTON, *Warminster*.

VOTES IN ELECTION.

In the following returns the Roses are placed in the order of merit—namely, first best twelve, second best twelve, and next best twenty-four exhibition varieties.

Mr. W. H. PALFREY, *Altrincham*.

VINE MILDEW.

THIS destructive pest which preys upon Vines has spread its ravages through several vineries this season, especially those that have been subject to it in previous years. From careful observations made for some time past the Vine mildew is, in my opinion, primarily caused by drought at the roots of the Vines. I do not say this is the sole cause of it; there may be many causes operating to bring about a diseased condition of the tissues of the Vine, subjecting it to disease.

Vine mildew is generally believed to be brought about by the atmosphere of the house being overcharged with moisture, and sulphur applied to the pipes and a warm dry atmosphere have been recommended as a preventive against its spreading. When first seen upon the Vine the fumes of sulphur will certainly kill this destructive parasite, but it is not advisable to use it if the disease makes its appearance as soon as the Grapes are set, for it will cause rust, as the skin of the embryo Grape is not sufficiently strong to resist its fumes.

I have found that the warm dry atmosphere of the vinery is suitable to the growth of mildew; the drier the Vine is kept both at the root and the air of the house the faster spreads the mildew, until it attacks every Vine. After hot dry summers the disease seems more prevalent than in wet damp seasons, especially where the soil used for the Vines is light and sandy, more so than when the soil is of a heavier texture. Where the roots of the Vine are in a cold saturated border and the internal atmosphere anything but suitable, or any other cause that will bring the Vine into a semi-starved condition, will subject it to the ravages of disease; still I hold that root-drought is the main cause, and most suitable to its development.

Three years ago three vineries were under my charge, all of which had previously been troubled with mildew. In the first house the Grapes were cut on the 28th of April, and being compelled to have many plants in the house forcing for conservatory decoration, the atmosphere was consequently kept moist, and no trace of mildew was to be found. The second house was treated differently. At the first symptoms of the disease the plants were cleared out and a warm dry atmosphere maintained, and in ten to fourteen days every Vine

was attacked with the exception of Malresfield Court Muscat, and not a vestige of the parasite was found upon it. When found to spread so rapidly under the dry treatment the borders inside and out were thoroughly watered, and from that time the mildew decreased. The third house was filled with Azaleas to make their growth. This house was kept very moist and the borders thoroughly watered as they required it, and the disease has never made its appearance. There is, I think, still something to be learned as to the cause and prevention of mildew. Will some of your able correspondents give attention to this important subject?—W. BARDNEY, *Norris Green*.

TEA AND NOISETTE ROSES.

No one can deprecate more than the writer the absurdity of making Tea and Noisette Roses first favourites at the expense of Hybrid Perpetuals. Practically speaking (for exhibition purposes I mean, of course) this never generally can be done. With a vast majority of rosarians, certainly those living in the northern parts of England or under the baneful shadow of manufacturing districts, scarcely any of the Tea or Noisette varieties can be grown, though occasionally they may exist; while the amount of success attained is utterly inadequate to the expenditure of trouble expended upon them: as our transpontine neighbours would say, *Le jeu ne vaut pas la chandelle*. These I know are truisms, still I could name many enthusiasts who year after year will keep on playing this losing game, while if they expended a tithe of their labour of love on Hybrid Perpetuals they would, in many cases at least, not only produce healthy plants and creditable blooms wherewith to gladden their eyes at home, but if so minded could compete with fair prospect of success at our leading Rose shows.

Mr. Laxton, the skilful raiser of most of our grandest English new Roses, is a signal case in point of what may be done under untoward circumstances. I remember well his writing to me, a good many years ago, how he had to bring his soil to his rosaries by railway in truckloads, while the air of the town in or near which he lived was dense with vapour from neighbouring manufactories. Now it is a matter of history in our Rose annals how Mr. Laxton's Roses sped. I can well remember their exquisite symmetry and colour, and how often, in spite of their want of size, their intrinsic merits promoted them to the highest honours; but I will venture to say no Tea Rose ever found a place in these exhibits grown in the open air.

Now while a low, or smoky, or otherwise chemically affected atmosphere is fatal to these delicately framed varieties, their value in a light poor soil cannot be too highly insisted upon, lavishly repaying the cultivator for any manurial adjuncts applied *ad libitum*, and this improvingly over a long number of years; whereas Hybrid Perpetuals would give but a partial and short-lived success through requiring periodical supplies of inorganic matter, such as fresh loam, &c., so absolutely essential to produce blooms suitable for exhibition. "WYLD SAVAGE," wise in his generation, endorses the truth of these remarks by drawing upon the Teas and Noisettes in his poor soil for a goodly proportion of his exhibition blooms, which seldom fail to be noticed somewhere in the prize list, though of late years, he remarks with a sigh, at the wrong end. But while I repeat I deprecate any comparison between Teas and Hybrid Perpetuals, it must be confessed that few exhibitors would like to exclude the former. Would it not be painful to think as to what without Teas must be the result of the Colchester, Salisbury, Cheshunt, and Torquay exhibits? A casket there would indeed be of precious stones but without the Rose diamonds. It is curious to notice how these and other exhibitors have their specialties, wisely no doubt growing most those varieties which flourish with them best. In the late *annus mirabilis* for Teas, continued down to this present date, Mr. Cant's exhibit of Boule d'Or will not easily be forgotten (so I hear, for I have never seen this difficult Rose expand yet), or his Souvenir d'Elise, a superb Tea Rose which this season seems specially to favour, and which should be in the smallest collection. Mr. Curtis also showed on several occasions magnificently Madame Hippolyte Jamain. I think that there never was a more exquisite bloom than of this Rose shown by this firm at the Alexandra Rose Show, where also Mr. Jowitt among amateurs showed a bloom of that uncertain Tea Rose Jean Ducher, which for immense size, substance, and colour was a perfect gem.

Mr. Baker seldom exhibits early or late without showing

that lovely and useful Noisette Madame Caroline Kuster, a variety not sufficiently known as its merits deserve, being one of the freest-growing and blooming Roses in cultivation; indeed, if Tea and Noisette Roses as a class came up to this standard the vexed question of admitting them in combination with Hybrid Perpetuals would *ipso facto* answer itself. Mr. Cranston often exhibits with great effect an old Tea I can confidently recommend, called David Pradel, a remarkably free bloomer, especially in autumn, when its large shell-shaped petals vary remarkably as to colour in separate blooms on the same plant from deep red to the faintest pink. But the belle of the season perhaps has been an old Rose little known to the public except as a pot Rose under glass, Tea Comtesse Nadailac. This excellent Rose seems one of Mr. G. Paul's specialties, as his firm several times exhibited fine specimens of this effective Rose; especially grand they were I was told at Manchester. Mr. Camm writes about this Rose at the West of England Rose Show at Hereford (where, as seen in the writer's stand, he pronounces it the premier bloom of the show), "as delicate and generally small." My experience is entirely the reverse. This Tea flourishes with me in surprising vigour; indeed, I have before me now two large finely coloured blooms I only wish my friend could see. No collection of Teas, I hold, can be complete without this distinct and useful variety.

Two of the most constant and lovely exhibition Tea Roses must by general consent be considered Catherine Mermet and Marie Van Houtte. Mr. Baker and Mr. G. Paul showed the latter grandly this season, although, perhaps, it would have been a shade more in character with a brighter summer. He would be a bold man indeed who would venture to ignore the claims of these two queens, or decide *ex cathedra* on their rival charms. Why, it would be the old tale over again of Paris introducing the apple of discord! In my humble way I am quite content (more especially as both their majesties agree admirably in my garden) to say with the country yokel—

"How happy could I be with either
Were t'other dear charmer away."

Commend me to the fair Catherine for perfection of maidenly symmetry and smooth and glowing yet of unfreckled untanned complexion; but what can surpass the equally fair Marie for matronly embonpoint and exquisite gradations of colour—the very faintest primrose coyly capturing the tints of the rosy-fingered morn?

I hope, with your permission, to forward a short descriptive list of old and new Tea and Noisette Roses which from experience I can fully recommend as distinct and useful, in addition to those I have already touched upon, which may have some interest with the public, especially as Mr. Hinton finds his Hybrid Perpetual exhibition election quite sufficient this year. I will conclude with a rather apposite quotation from the Laureate's "Queen Mary;" lines which, although referring primarily to that "queen of a day" the peerless Lady Jane Grey, may, by a fair poetical licence, be transferred to the subject of this paper, a perfect Tea Rose—twin bud and blossom—

"Rose of grace,
Girl never breathed that equalled such a Rose:
Rose never grew that rivalled such a bud."

—HEREFORDSHIRE INCUMBENT.

THE CRYSTAL PALACE.

THIS place of recreation is deservedly popular with all classes resident in London and its vicinity, and also with strangers who visit the metropolis from all parts of the world; gardeners, too, when in London on a tour of inspection would be well repaid for a day there, as among its many and varied attractions not the least important are the extensive and well-kept grounds. The site of the Palace was well selected, as a better spot for a view of the country around London it is impossible to find. This elevation, although giving good scope to the landscape, which has certainly been made the most of, militates very much against the efforts of Mr. Thomson the skilled Superintendent of the horticultural department, shelter being very requisite to many kinds of shrubs and plants necessarily employed. This being the case it was all the more surprising to find the beds of Pelargoniums and kindred bedding plants looking so bright and well late in September—in fact, as bright as we usually see them in July or August.

The sight presented to the visitor on arriving at the low-level station entrance is very grand indeed. Directly opposite is the rosery, an elevated and elaborate structure of trelliswork

intended for climbing Roses. These, however, in consequence of being too much exposed are a failure, and are being gradually superseded with Ivy. The base of this structure is surrounded by a bank beautifully festooned and figured with Pelargoniums in variety, *Iresine Lindeni*, *Tagetes signata pumila*, *Lobelia*, *Alternanthera*, &c. The *Tagetes* is kept pinched back, and by this treatment a beautiful green-foliage plant is obtained, which contrasts well with the other plants, and also helps to make a groundwork for the most prominent plant forming the festoon—*Pelargonium Golden Superb Nosegay*. The latter variety is here considered superior in point of colour to the old *Crystal Palace Gem*. Some idea may be formed of the grandeur of this bank when it is stated that upwards of twenty thousand plants are used on it.

On the bank immediately below the walk surrounding the

foregoing are a series of eighteen circular carpet beds alternating with beds of dwarf Roses. These carpet beds are all dissimilar, and so bright and well do they look, even on the north side, that it is almost impossible to decide which are the best. Fig. 39 will help to give some idea of their effect. A great variety of plants are used in all the beds, which makes them more interesting than where two or three varieties only are used. *Kleinia repens* is a very effective bluish grey plant for lines, and another silvery grey plant likely to become popular is the *Saxifraga longifolia*. The *Mentha Pulegium gibraltarica* is the best green plant used. A mixture of *Alternanthera amena* and *Sedum acre elegans* is very pleasing wherever placed. *Pelargoniums Golden Harry Hieover* and *Mrs. Pollock*, and *Lobelia pumila magnifica* are freely used in the carpet beds and with good effect. One man only is re-

Fig. 39.

7, *Mentha Pulegium gibraltarica*.
8, *Golden Feather Pyrethrum*.

quired to keep the carpet beds in excellent trim. On the lawns near the above plain beds are placed at intervals near the walks. These in most instances are simply but very effectively planted. Beds filled with a mixture of bronze *Pelargonium James Richards*, and which are allowed to flower, with *Centaurea candidissima*, *Gazania splendens* and *Lobelia Blue King*, *Amaranthus melancholicus ruber* and *Centaurea candidissima*, edged with *Pelargonium Crystal Palace Gem*, and *Verbena venosa* and a silver variegated *Pelargonium*, are all very pleasing.

Opposite to these in the direction of the Palace are several beds filled with bedding Dahlias. These look remarkably well, and will doubtless have the desirable effect of stimulating the use of this class of bedding plants. The following varieties are used:—*Alba floribunda*, white; *Rising Sun*, scarlet; *Titian*, yellow; *Zelinda*, purple; and *Golden Gem*, yellow.

Near these fine autumnal beds is the only sheltered spot where subtropical plants can be employed, and of these there are only a few in number. One bed with a centre group of *Ricinus Obermannii* surrounded with *Ferdinandia emimens*, these again with *Wigandia caracasana* edged with *Dell's Crimson Beet*, fringed with *Festuca glauca*, is highly effective, the purplish stems of the *Ricinus* being very discernible. On the right and left of the walk leading up to the lower terrace

steps are two long beds attractively filled with groups of evergreen, variegated, and coniferous plants. Limited space forbids a lengthy description of these much-admired beds, which contain several varieties of *Retinosporas*, and flowering groups of *Sedum spectabile* just now greatly enliven the arrangement.

The terrace garden with its central fountains and numerous and well-arranged beds is also looking well, and the alterations recently effected by Mr. Thomson are a marked improvement. Private gardeners would do well if, instead of putting their whole stock of bedding plants into one or two places, they followed the plan so well carried out both at the *Crystal Palace* and parks. A combination of beds is doubtless very grand, but it has the effect of making the other part of the grounds comparatively dull. On the other hand, if the beds were distributed throughout the grounds the interest and pleasure is sustained, the beds being shown up by the turf, and by their very brightness improving rather than detracting from the appearance of the Conifers, shrubs, &c.

Many varieties of Conifers and other shrubs from causes given above do not thrive in the Palace grounds, and some of the delicate and rather unsightly specimens are being replaced by hardier sorts, such as *Pinus austriaca*, &c. On each side of the grand terrace steps leading up into the Palace are two long

borders, filled at the back with Rhododendrons and in front with a great variety of succulents, including the following:—*Sempervivum canariense*, *S. arboreum variegatum*, *S. umbilicum*, and *S. serrulatum*, very tastefully and effectively grouped. The beds on this terrace extend at intervals the whole length of the Palace, and have been very fine indeed, but many of them are damaged by the frequent displays of fireworks held near them.

The following Pelargoniums are favourites at the Palace:—Mrs. Turner, deep pink; *Triomphe de Stella*, scarlet; Waltham Seedling, scarlet; *Gloire de Corbenay*, pink; Lady Kirkland, deep rose; Bonfire, scarlet; Amaranth, and Christine. Black Douglas is the best bronze-foliaged variety. *Ageratums* Lady Jane and Countess of Stair are both good and useful.

The plants in the tropical stove are looking very healthy, and the plants throughout the Palace are in admirable condition, the Tree Ferns being particularly good. *Chrysanthemums* in large numbers will eventually produce a display well worthy of a visit by the lovers of this useful plant. In conclusion I believe I can safely say that the grounds never looked better, and that in Mr. Thomson the Crystal Palace Company have a most efficient manager well worthy of this fine place.—W. J. O.

DRESSING CARNATIONS.

It is quite according to my nature that I should write wild of any subject, but I do not see that I am so wild of the mark as Mr. Douglas supposes.

I believe gum has been used before now, if not in Carnations, at all events in other flowers. Mr. Douglas says that dressing is not requisite for the Rose. He is right; it is not, no more is it for the Carnation. I think a clever operator might dress to advantage several Roses. Etienne Levet, for instance, is a Rose no one cuts without misgiving; it is so beautiful on the tree when half opened; but we all know that in a short time its petals are so few that it will show an eye. If, however, we could close the eye up like Beauty of Waltham does for herself, then we should have no eye seen in her also.

"D., Deal," has proved that it is quite possible for an undressed Carnation to beat a dressed one by telling us how Mr. Rudd, a most excellent florist from the north, won the premier prize with a bloom cut and exhibited as grown. Then why should we have this stilted unnatural form of exhibiting these lovely plants?

Mr. Douglas says he has never seen a bloom when dressed so altered that he should not have known it. Well, I can only say that Mr. Charles Turner told me that an exhibitor of Carnations left his stand for a short time, during which he dressed his flowers. On returning, the exhibitor admired the blooms exceedingly, and asked whose they were. The answer, "They are your own," sent him into a seventh heaven of delight.

Some people, I know, can grow Carnations but cannot dress them, and are obliged either not to exhibit or to show them undressed. It has been hinted to me that Mr. Douglas himself either cannot or does not dress all his Carnations, but calls in the aid of an expert dresser before exhibiting at the great shows. If this be the case, to whom should the prize go—to the grower or the dresser? As dressing seems to be the *sine quâ non* of exhibiting, it would seem as if the dresser should have it; but if a more natural state of things existed then the grower would of course take it.

With regard to a letter signed "A GILLYFLOWER," I have to express my gratitude, not only for the kind way in which your correspondent treats my remarks, but also for the liberal offer he makes me. Of course I shall most gratefully accept any plants he is good enough to send me, yet at the same time I do not see my way to showing Carnations.

I must now answer some questions which "A GILLYFLOWER" puts to me. He asks, "Does not 'WYLD SAVAGE' dress the Rose at all?" Most certainly not, is my reply. "Are the fine flowers he shows the natural growth of the half-starved stunted plants which are grown in his garden?" Most decidedly they are, just as they are cut from the plants. "Does he add a leaf or two, sometimes a bud, to his flower?" Never, I reply; if I did so I should be cheating, and even if I escaped detection should be breaking one of the laws of Rose-showing. The addition even of a leaf will disqualify. The Rose must be shown as grown. "Does he tie the flowers up with a piece of twine or bast, and cut the same just before leaving the stands for the judges to go over?" I have never done such a thing in my life. I have never even brought a Tea Rose up to a show with a piece of bast tied round it, though I am aware

some exhibitors do this; but if I did I should not be dressing in the way a florist dresses a Carnation. I never heard of a man dressing a Rose beyond removing a dead petal.

"A GILLYFLOWER" certainly makes out a very strong case for dressing; he almost claims for it the old Latin rule, which says that which has always been done, which is done by all people, and done everywhere, must be right. But all this does not in the least degree detract from our point, which is that the custom is a barbarous one and ought to be disallowed for the future.—WYLD SAVAGE.

NECTARINES.

YOUR correspondent "A KITCHEN GARDENER" has, on page 200, communicated practical notes on the Nectarine, but I differ from him in some of his remarks. First, I think the Nectarine must be placed second to the Peach, not that it is less hardy, for I think it much harder than the Peach, but that the fruit is not nearly so much esteemed. I am seldom asked for a Nectarine, but Peaches are always wanted. If again we adopt the advice to put up light houses to grow these fruits in, an idea I strongly support, I would plant it with Peaches rather than Nectarines, especially if the fruit is grown for sale, as the former would make double the price the latter would. A good Nectarine is an agreeable change to a Peach, but I never heard it spoken of as its equal. A 2-feet deep border would do well in a heavy wet soil, but in a high dry situation I would say 3 feet.

And now as to varieties. Lord Napier is really the best. It is a fact I cannot account for, but here Elruge is most disappointing. I had thought it the best for some twenty years, but of late I have found it inferior. Hardwicke Seedling is good in all points, and earlier than Elruge. Violette Hâtive is fair; but let me name a substitute in that noble Nectarine Balgowan. This is altogether the best Nectarine grown except Lord Napier, and the two together cannot be beaten in any way. Balgowan is later than Violette Hâtive, with more the growth of the White Nectarine—strong, clean, and handsome in foliage and fruit. It is a free bearer, and I have seldom seen mildew on it, or in fact any of the ills Nectarines and Peaches are subject to. Pitmaston Orange, or rather Pine Apple, which is decidedly better flavoured, I would place third to the above two. Newington I would not have at any price; I simply consider it the worst Nectarine grown.—J. TAYLOR, *Hardwicke Grange*.

THE WARS OF THE ROSES.

CORDIALLY do I join with Rev. Canon Hole in applying for an interim injunction to restrain "WYLD SAVAGE" from awarding permanent first and second prizes to our Rose friends Messrs. Baker and Jowitt before future exhibitions are even held, and I decline to shut out in any spirit of bumpiousness all other competitors against ourselves for the assumed positions of third and fourth assigned to himself and me. True, we find a considerable difficulty in competing favourably against Rose grounds in full bloom, when we can scarcely make up our stands because our Roses are not out. I at least feel also somewhat swamped by mere numbers, as with two thousand plants I contemplate those "who come against me with twenty thousand;" but if we could equalise the conditions all the usual good exhibitors would do "as well as each other, probably better," as Lord Dundreary would say, then cultivation, judgment, and taste would tell.

The true Rose-growing fraternity know well enough that those who take the highest prizes (especially if only at the early shows), are not, therefore, necessarily the best rosarians. Victory at Rose shows generally sides with the largest battalions of plants; and whatever the general public may imagine, Rose-growers clearly understand that the contest is not one of superiority of culture as between different exhibitors, but merely a trial in which seasons, dates, distances, and numbers tell in favour of some and to the disadvantage of others.

For those who like myself grow comparatively few plants there is always this consolation, that when Goliath conquers David he has nothing to be very proud of, but when David conquers Goliath he ought to be allowed to crow a little.—EDWARD N. POCHIN, *Barkby Vicarage*.

I MUST decline further discussion with one who ignores the simple fact that we rosarians of the midland and northern counties cannot compete with the southern exhibitors at their early shows, and who sees no proof of this statement in my

victory over one of his two invincibles at Manchester, the other, though he had entered, declining to show; but I must take this opportunity, on behalf of many rosarians, to assure "WYLD SAVAGE" that remarks upon Roses by one who does not realise them in their perfection affect us no more than a slight overflow of the Cam would alarm the University of Cambridge.—S. REYNOLDS HOLE.

NOVELTIES IN THE ROYAL GARDENS, KEW.

BEGONIA STARLIGHT has taken the attention of horticulturists, and we cannot do better than point out a specimen in the cool end of the T range. It is the production of Col. Clarke, who gave to the world the invaluable *B. Weltoniensis*, and is the result of crossing *B. insignis* with *B. Pearcei*. The latter has brought to order the straggling habit of *B. insignis*, has relieved it of its pink colour while imparting none of its yellow, and the result is almost a pure white. Its points of merit are dwarf shrubby habit and great profusion of flowers; with it to grow is to bloom, which it has done all the summer, and by judicious resting at this season it can be made one of the best of winter-flowering plants. Another hybrid raised by the same gentleman called **Sunlight** is also of merit, but the flower stalks are so long that above the foliage it has a loose habit. The colour is rich orange, obtained by crossing *B. Pearcei* with *B. cinnabarina*. The former is an excellent parent for experiment, having a very compact and floriferous habit; in itself it is nearly perfect with regard to a kind of good habit with golden yellow flowers. The advent of this beautiful class marks an era in floricultural progress.

Still in the same compartment we notice a specimen of the rare and curious *Brunsvigia Josephina*. It bears an umbel of flowers scarcely surpassed in size by any bulbous plant. The individual flowers resemble *Nerine*; they are sharply depressed at the end of a straight stalk, often a foot in length; the colour is red, irregularly marked with orange, and a single umbel may consist of forty blooms. It comes from the Cape, and is of the choicest character for bulbous collections. *Hæmanthus coccineus* is also sufficiently rare to receive notice; there are two fine pans, each with about a dozen immense flower heads. The florets are densely packed within several large fleshy scarlet bracts, and these no doubt by many are supposed to constitute the perianth. It also comes from the Cape.

The *Victoria regia* this year has shown a peculiarity; its flowers, instead of reposing on the water, are raised from 6 to 8 inches above, standing firmly erect. A large picture we are aware was once condemned on account of exhibiting the same circumstance, now, however, proved to be a truthful representation. Around this tank are many plants of interest; one of these, *Zizania aquatica*, will shortly be in flower. It is a Grass, the stems of which form a valuable material for paper-making, though best known on account of the value of its seeds, which are said to equal the best rice, known as Canada rice; it affords food for countless flocks of water fowl. The plant until the spring of this year had long been out of cultivation; young plants were then obtained for the Royal Gardens, seeds being quite useless, as they soon lose their germinating power. Another interesting plant, with the addition of considerable beauty, is *Monochoria vaginalis*. It is nearly allied to *Pontederia*, of which it has much the aspect, but the leaves are much larger. The flowers are blue, collected together in a mass, and appear as if growing from the petiole, a leaf above being in direct line with the stem. When young it is eaten in India as a pot herb, and is used also medicinally for disorders of the stomach and liver. It is considered when chewed a remedy for toothache. *Reana luxurians* is a Grass, about which much has been said for its alleged value as a forage plant. It is a native of Guatemala, and has been tried in the most favourable parts of France without any result to show the ground of its reputation. Here it reaches a height of 10 feet or more, and has something the appearance of Maize. It is proper to add that rightly it is called *Euchlena luxurians*. *Ceratopteris thalictroides*—the only truly aquatic Fern, and a great rarity in collections—is extremely pretty, especially in its fertile fronds, which are tripinnate with narrow segments. It has a most graceful habit, and but for its succulence would be useful for decorative purposes. Like all water plants it is widely distributed, growing in all the tropics. It is one of the very few annual Ferns, and produces its spores in immense quantities.

In the herbaceous collection several novelties may be found, the most choice for the moment being *Meconopsis simplicifolia*, a Poppy of the Himalayas, hardly suggesting its relationship.

It has a tuft of narrow undivided leaves resting on the soil, from the centre of which arises a single scape bearing a single large purple flower. In this particular it differs from other species with which we are acquainted, all these having a large number of flowers on the same stem. Next in order of rarity are *Kniphofia sarmentosa* and *K. Macowani*. They are species of the genus known to some as "Red Hot Pokers," justified to the greatest extent by the well known *K. Uvaria*. These are much smaller in growth, and when out of flower are ornamental on account of their glaucous leaves. *Castilleja indivisa*, introduced by Mr. Thompson, is still in flower, or rather in bract, these having all the colour and size; the flowers are small and comparatively inconspicuous.

Passing through the Orchid houses, even at this dull season we find much to entertain. *Dendrobium cumulatum* has clusters of flesh-coloured flowers at intervals along the stems, and from its similarity to *D. mutabile* is suggestive of use for the same purpose, that of making buttonhole bouquets. *Lælia Dayana* is flowering nicely on a block, *Masdevallia* is represented by *M. Veitchii*, and *Miltonia* by *M. Clowessii* and *M. candida grandiflora*. Coming to *Cypripedium* and *Oncidium* there are several kinds of each. Of the first *C. Sedeni* is no doubt the most choice; then follow *C. concolor*—growing in chalky loam, and showing that it likes this exception to the usual treatment for *Cypripedia*—*C. longifolium*, and, as we think it should be placed, *C. longifolium* var. *Roezlii*. *Oncidium Kramerii* is a most beautiful species, and a Butterfly Orchid is always of interest. *O. tigrinum* has a fine pale yellow lip and barred segments. *O. flexuosum* has a number of small pretty flowers, and lastly *O. triquetrum* is curious; it is one of the smallest species, looking best and even attractive when placed thickly together on a stem. Its flowers are brown and frequently present. A native of Jamaica.

THE ROSE ELECTION.

WHAT am I to think of the election? Surely it must be a mockery to me; for can anything be more mocking than to be placed in the election the seventy-first out of seventy-two Roses, the penultimate number in this grand election being the Rev. John B. M. Camm? Is it any wonder that I am wylf? I look for comfort at the returns, and I see that some kind friend has placed me in the first twelve. Another gleam of comfort to be derived by me from the declaration of the poll is that Catherine Mermet is in the first twenty-four, and that at least is something; while Gloire de Dijon has descended to fifty-nine [it was No. 59 last year], in the forty-eight and is not mentioned by a single nurseryman, which is a state of things highly consolatory to one who has written to this effect for years.

On this occasion the election, I feel bound to say, that though to me it is a mockery, it is neither a delusion nor a snare to me or anyone else. It is a most valuable return, and the two tables, the seventy-two and forty-eight, furnish us with not only a novel, but a most useful table of reference. As an organ builder said to me on completing a large organ, "You will find it will take you years to find out all the combinations of stops that you can make;" so it will be many weeks before I shall have exhausted all the interesting information which the declaration of the poll conveys. The labour of drawing up such a return must have been very great, and I, as I think I have done on all previous occasions, lose no time in thanking Mr. Hinton for the trouble and labour that he has expended upon this work. Perhaps Mr. George Paul will show his appreciation by naming his next seedling after the returning officer; if he does, let us hope that when the election comes he will not find his name placed No. 71 in one list and not mentioned at all in the other.—WYLD SAVAGE.

PRESERVING FRUIT WHOLE.

THE art of preserving green fruit in bottles and ripe fruit in jars of syrup is well known to all cooks, but unless the operation is done very carefully the fruit very often does not keep well, being apt to be mouldy and to lose flavour. A friend of mine, an Edinburgh nurseryman, who lately stayed with me on his way back from Paris, told me that in the Exhibition there his attention was attracted to some preserved fruits in a very perfect state. On making inquiries as to the process of preserving he was informed that the price of the secret was five francs; on paying this he was told that it was accomplished by placing the fruit in a close box or press with

a gallon of water in a jar and two table-spoonfuls of sulphur in a tin. The sulphur is set fire to and the whole is kept close until it is consumed, when the fruit is taken out in a state that will remain perfect for two years. It is an American discovery, and as it is well known that sulphur has a great power of killing the germs of disease there may be something in it, and I would be pleased to hear the result from anyone who may try the experiment, as I intend to do.—A KITCHEN GARDENER.

CAPE HEATHS.—No. 9.

It will be well now to place these plants under cover. Many growers prefer to repot their young specimens at this particular

Fig. 40.—*Erica verticillata*.

season, and we would recommend it to be done now at once. Use good sandy peat, and above all things drain the pots well. Do not break the soil too small, and in potting press it very firm. The plants should be kept a little closer directly after potting, but avoid keeping them too much confined. Keep a sharp look-out for the great bane of *Ericas*—viz., the mildew. Upon the slightest sign dust with flowers of sulphur, but keep it carefully away from the roots.

Erica verticillata (fig. 40).—Leaves arranged in fours, linear acute and brilliant green. Flowers pendant, tubular, flame colour, produced in pairs from the axils of the leaves, forming long racemes. Very showy.

E. Austiniana.—This is a very fine hardwood species. Leaves spreading, smooth, and dark green. Flowers produced in large whorls, nearly terminal, tubular, nearly an inch long ;

tubes carmine streaked with white ; neck encircled with a dark band ; segments large and spreading.

E. taxifolia.—An elegant species belonging to the arborescent section, which are very difficult to raise from cuttings. Leaves arranged in threes, linear, smooth, and bright green. Flowers in terminal clusters, globose ; both calyx and corolla rosy pink.

E. Turnbullii.—A superb autumn-flowering variety. Flowers produced in umbels of about six, tubular ; tubes $1\frac{1}{2}$ inch long, reddish pink, becoming much darker when fully exposed to the sun's influence ; neck encircled with a dark band ; segments white, large and spreading.

E. tricolor Holfordii.—A robust-growing variety. Leaves densely clothed with long woolly hairs. Flowers tubular, very large, and produced in many-flowered whorls ; tubes soft flesh colour, with a darker circle round the neck.

E. tricolor coronata.—This variety often flowers earlier than the present month, but we have seen it very fine at this season. Less robust than the preceding. Flowers large and tubular ; tubes rosy pink, with a band of green round the neck ; segments of limb white, spreading.

E. tricolor flammea.—Leaves blunt, recurved, and densely furnished with long woolly hairs. Flowers upwards of $1\frac{1}{2}$ inch long, much swollen at the base, fiery red, changing upwards to white with a green band round the neck ; segments spreading.

E. Marnockiana.—A very fine hardwood species. Leaves spreading, fringed at the edges with light hairs, and armed at the point with a stiff bristle-like hair. Whorls many-flowered, tubular, swollen at the base, destitute of the gummy matter so common to this section ; tubes deep rich blackish purple ; segments small, spreading, white.

E. sulphurea.—Yellow Heaths are not plentiful at this season, and therefore this is a very welcome species. Leaves arranged in fours, hairy. Flowers tubular, also hairy, forming long racemes near the apex of the principal branches, pale yellow.

E. pyramidalis (fig. 41, page 261).—A very ornamental species, both in regard to its mode of growth and to its profusion of flowers. Leaves pubescent. Flowers funnel-shaped, rose-coloured, with a protruding style.

NOTES AND GLEANINGS.

WE regret to hear that the TOMATO HARVEST in Fulham has turned out a comparative failure. Many cartloads of diseased fruits may be seen in some of the market gardens. The disease is of a very bad type ; the plants are taken in the morning and in some cases are perfectly black before sunset. The only chance of securing the fruit from diseased plants is to gather it immediately the disease is seen, and ripen them under glass. In many cases more than half the crops have been thrown away.

— AN excellent judge says that one of the best FLOWER BEDS he has seen this season is at Pendell Court, the seat of Sir G. Macleay, under the care of Mr. Green. It is oval in form, and is strongly suggestive of a bright gem judiciously set. The centre is planted with Tuberous Begonias, leaving a broad band for the purpose of toning and contrast. This is effected to perfection by *Centaurea ragusina*, *Coleus*, *Ageratum*, and variegated Ivy-leaved *Pelargonium*, the whole trimmed off with a margin of *Alternanthera*. The leaves of Tuberous Begonias out of doors are often bronzed to a degree that does not suit the flowers, but at Pendell Court they had the brightest green colour.

— MR. G. MURRAY, Peniarth Gardens, North Wales, writes to us as follows on MANDEVILLA SUAVEOLENS :—"With me this climber has flowered twice this summer, and from the first flowering there are seed pods from 12 to 16 inches long hanging on the plant. It is growing on the south side of the mansion, and has attained the height of 30 feet. I should be pleased to know if it has seeded with anyone before in the open air."

— MR. P. BENNETT, Colebrooke Park, Tunbridge, in reply to "A KITCHEN GARDENER," writes as follows on TOMATOES KEEPING WASPS OUT OF VINERIES :—"Tomatoes planted on the back wall of the vinery have produced a large quantity of good fruit, and I have never seen one wasp in the house, though the Grapes have been ripe for six weeks. The cottage I occupy, which is not 10 yards from the vinery, is and has been swarming with wasps and flies ; and other fruit trees are much infested with them. I am at a loss to account for the wasps keeping out of the vinery except for the presence of Tomatoes."

— RHUBARB, says Dr. Birdwood in his "Handbook to the Indian Court at the Paris Exhibition," is mentioned by Dioscorides as brought from beyond the Bosphorus, and the Rachoma of Pliny, which he says was brought from beyond Pontus. It is a native of south-eastern Thibet and the western and north-western frontiers of China, and is said to be mentioned by Chinese writers B.C. 2700! The Rha, which came into Europe by the ancient caravan routes from Northern China by Bokhara and Asia Minor, was naturally called Rha-ponticum, and that by Russia and the Danube Rha-barbarum. The designations Turkey, Russian, East Indian, Canton Rhubarb merely indicate the commercial channels through which Rhubarb has been derived in modern times. It is a good illustration of the obstructions which are still put in the way of the trade of India with Thibet and Western China, that if the Viceroy and Governor-General needs a Rhubarb pill, instead of getting it at once through the Himalayan passes, he receives it round about by way of Kiachta, St. Petersburg, London, and the Atlantic and Indian Oceans. The Rhubarb now obtained from Hankau is the root of *Rheum officinale* of Baillon, a native of Mongolia; but undoubtedly the true plant, the source of the best Turkey, or Russian, Muscovite or Kiachta Rhubarb, is *Rheum palmatum*, the Sharo-moto of the Mongols and Djemtsa of the Tangutans.

— MR. THOMAS ROWLANDS, foreman at Mr. Bass's gardens at Rangemore, has been appointed gardener to the Viscountess Downe at Baldersby Park, Yorkshire.

— ON the occasion of the visit of the Scottish Arboricultural Society to the estates of the Earl of Mansfield at Scone, as reported in the "Journal of Forestry," Mr. M'Corquodale, forester, pointed out a very effectual mode of preventing the RAVAGES OF RABBITS AMONGST THE YOUNG TREES, by the placing of boards firmly fastened with wire round the stems, and which are removed before the tree becomes too large, and replaced by wire fencing. The boards are about 30 inches in length, 3 inches wide, and half an inch thick, and may be cut of any third-rate timber too small or worthless for any other purpose. Four to six of them can be quickly bound loosely round the foot of each tree, and are as easily removed when the growth of the stem renders it necessary. The method is thoroughly effective, and none can be applied more easily to trees of a suitable size, say 5 to 15 feet in height. Mr. M'Corquodale also stated that while *Abies Douglasii* grows at Scone with great vigour *A. Menziesii* appears this summer to be everywhere decaying, the injury being attributable to late spring frosts.

— LIGHTNING AND TREES.—It cannot be too often repeated at this season of the year, when thunderstorms are so frequent, that one of the most dangerous places in which to seek shelter is under a large tree. Of all the persons and animals killed by lightning probably eight-tenths have been destroyed under or near trees. Oak trees more frequently than any others draw lightning from the clouds, partly perhaps because the close grain of the Oak increases its conducting power, and partly because the sap of the Oak contains a large quantity of iron in solution which, by impregnating the wood and bark, has the same effect. But no tree enjoys the exemption of the Banyan, which, at least as the Hindoos believe, is never touched by lightning. The *Pittsburg Commercial* takes the recent disaster at a picnic near that city as a text from which to give its readers some good advice about avoiding trees in thunderstorms, and makes the practical suggestion that the proprietors of groves frequently rented for picnics and such entertainments in the summer should provide one or more substantial sheds for the accommodation of parties in case of a sudden storm.—(*Mississippi Lumberman*.)

— THE *Queenslander* notes the cutting of a GIANT EUCLYPTUS felled in the Dandenong Range, Australia, that had attained the height of 300 feet. The following were its dimensions:—At 1 foot from the ground the circumference was 69 feet, at 12 feet from the ground the diameter was 11 feet 4 inches, at 78 feet diameter 9 feet, at 144 feet diameter 8 feet, at 210 feet diameter 5 feet.

PIPPINS.

ABOUT five miles to the north of Lewes in Sussex is a village dignified by the name of Plumpton, which being translated signifies "The town amid a clump of trees," a town that would have attracted no notice if in a moated house, still there existant, had not resided Leonard Mascall who is said to have

first introduced Pippins from the Continent. What these Pippins were we have no means of knowing, and we find no clue to discover. Mascall also first brought carp from the Continent into England, and cultivated them in the moat which then was and still is around the house.

Of Leonard Mascall's family the earliest notice in the parish register is "Edward Mascall baptised" in 1592. Of the house in which they resided I could discern no remains but the chimneys, which are of the Elizabethan era. The remainder of the house is more modern. The pond in which Mascall had his carp still remains, and beneath a row of Elms yet existing he probably walked.

Recently a search was made a second time in the registers of Plumpton in Sussex relative to the family of Leonard Mascall in the hope of finding more details, but the search was almost fruitless. The earliest entries in the register are of the births of several females of the family in 1558; and of the burial of Richard Mascall in March, 1569-70. We pub-

Fig. 41.—*Erica pyramidalis* (see page 260).

lished the portrait of Leonard Mascall and all the information we then gleaned in the *Journal of Horticulture* dated January 28th, 1875.

A SUMMER DAY'S STROLL.

THE Heather had opened its flowers into full summer beauty, the month was August, the morning fine when I essayed to fulfil a promise long made to visit the gardens of some of my neighbours to see, mark, learn, and to discuss their doings, their trials, triumphs, and failures. Ashdown Park, Plaw Hatch, and Brambletye were within my reach, and my route was across Ashdown Forest, a forest only in name now, the greater part being denuded of trees—a wild waste of Heather Fern, Broom, and Gorse, extending over an area of some twenty square miles, the last remains of that huge forest, the Andredswald of the Saxons, called *Sylva Anderida* by the Romans, and which in their day extended from Kent right through Sussex into Hampshire for a distance of 120 miles.

On the confines of this waste coins bearing the impress of Agricola and Vespasian were found among some slag of the old Roman ironworks a few years ago; and I have in my possession some pieces of charcoal which I picked out of another heap of slag as it was excavated from beneath a superincumbent bed of

soil, which must be at least fifteen hundred years old, and yet is still so hard as to show the annual growth of wood as clearly as when it was first burnt, a little of the outside only crumbling to the touch. What do the advocates for using charcoal in garden soil think of this slow rate of decay?

Beauty, brightness, freshness prevailed in the forest; the Heather was alive with bees, great cushions of the deep pink flowers of *Erica cinerea* sparkled on many a gravelly hillock, whole acres of the lovely *Erica tetralix* were covered with large pale pink flowers, more delicate and refined than those of many a rare Cape Heath, while there were such quantities of grey Sphagnum as would delight the heart of an Orchid grower. On some of the upper slopes beds of the rare *Gentiana pneumonanthe* with three and four large blue clustering flowers on a stem were just expanding into beauty. Lower down, where springs of water burst out from the hillsides and occasional swamps were seen crowded with mosses, some green, others crimson, with various shades of yellow, orange, and brown. The Sundew (*Drosera rotundifolia*) in full bloom, every leaf a picture in miniature, nestled abundantly among the moss; there were also occasional patches of *Menyanthes trifoliata* (the Bogbean), but I was too late to find any of its exquisitely feathered white flowers, yet it was worth a walk of miles to see the lovely clusters of blue Marsh *Campanula* flowers trailing along the edges of the swamp; and about the centre, quite out of my reach, an occasional Cotton Rush still retained its long white bearded head.

Through this natural flower garden I went, pausing occasionally to watch the cloud shadows sweeping along the wide slopes, to admire fine views which kept opening out between the hills right across to the lofty South Downs bounding the distant horizon. Many a nimble lizard dashed across my path, many a curious insect flitting among the flowers tempted me to stop again and again, for "the forest" is a regular paradise for entomologists as well as for botanists. At length I reach Ashdown Park, and soon find the gardens and the gardener, Mr. Down, with whom I spent a pleasant hour, seeing and talking about matters that will amuse and instruct the readers of the Journal when my notes on Ashdown Park and its garden are published.

Under Mr. Down's friendly guidance sufficiently far to make my way clear through another portion of the "forest," I went on to Plaw Hatch, the seat of W. Arbuthnot, Esq., where I found Mr. McBean engaged in the arduous task of converting a poor thin soil into a fertile garden, and exceedingly well was he doing it. Like most of the new houses that are springing up with such marvellous rapidity in this part of Sussex, Plaw Hatch occupies a commanding position, overlooking magnificent and varied scenery. The building is massive and substantial in character, having a carriage court on the north side of agreeable proportions to the buildings, to which it affords access on the west side, a terrace overlooking a subterranean now in course of construction, and on the south side a conservatory with a level expanse of lawn and beds well filled with summer flowers, and with two exceedingly bold central masses of soft rich velvety *Coleus*. The conservatory was not a large one, but it contained some of the best groups of plants I had seen for many a day. Cultural skill of a high order and facility of arrangement had been brought into play here in a manner that is not by any means common. On one hand, some Palms lent the influence of their elegant frondage to the gay-flowering plants with which they were intermingled; on the other, two or three fine specimens of *Coleus* trained cone-shaped without formality gave richness and warmth to a tasteful combination of other foliage plants of more sober hue. These groups were only two beds of plants in pots, for there was no staging—nothing for the eye to rest upon but the plants; and this, when good taste is brought to bear upon the grouping and such good plants are used, is, I think, the best mode of conservatory arrangement.

From the front of the conservatory the sight was a pleasant one; the gay masses of summer flowers in the beds told well upon the close-mown lawn, which is level among the beds and ascends a slope to shrub beds and borders on the east side, forming so excellent a background to the garden as to cause one to regret it was not continued along the south side, where the lawn is made to ascend several feet by an abrupt slope to another level space, where more small beds were planted with hardy Heaths and dwarf flowering shrubs. Beyond this garden of hardy flowers a path led through more lawn and shrub beds to the kitchen garden—a square plot enclosed with substantial walls, and well cropped with vegetables, fruit trees being

planted along the margins of the paths and against the walls, all in a flourishing condition; a large open water tank in the centre, concrete paths of tar and sand, firm, clean, and pleasant to walk upon in all weather, with a neat edging of tiles, and, pleasant sight, no weeds. There was a range of lofty fruit houses along the north wall—vineries with vigorous young Vines bearing some noble bunches of Grapes of various sorts, and all alike good, those of Muscat of Alexandria being especially remarkable for the golden colour of the large symmetrical bunches. Peach and Fig houses were also satisfactory, every tree in flourishing condition, and most of them beginning to afford some fruit.

Outside the kitchen garden, behind the north wall, were other houses—a long low span-roofed Rose house, snug little houses where late crops of Cucumbers and Melons were just being started, and a large stove crowded with plants so well grown and so rare withal that one could have spent a day profitably among them. I was obliged to rest content with a glance at the noble forms of Marantas, Ferns, and grandly grown *Caladiums*, and to admire the tasteful way in which every inch of space along the margins of the paths and under the side stages was carpeted with a mingled growth of Lycopods, *Fittonia*, *Tradescantia*, Ferns, *Caladiums*, and *Gymnostachyum*. I left Mr. McBean with that pleasant feeling which arises from the sight of work well done and energy well applied; and so on to Brambletye, which lay right before me, full in sight upon the crest of a hill some three miles off.

Brambletye has already been so fully and well described in this Journal that I have now only to tell how everything about the gardens continues to be well done. Mr. Jenks is to be congratulated upon his fruit crops in this year of scarcity. Numerous Plum trees on walls were heavily laden with fruit; Pears, too, on walls had abundant crops, but the greatest wonder was the Peach wall with a simple glass coping projecting from the top of the wall, and to which a canvas screen is fastened to protect the blossom and tender foliage in spring. Mr. Jenks asserts that he always has a crop of fruit by means of this simple agency, and certainly this year he not only has a crop, but enough fruit for two crops; there is the wall 300 feet long completely clothed with healthy Peach wood, all laden from top to bottom with fruit. Other Peaches under glass were also bearing a plentiful crop; the Grapes in the various vineries were all good, but the Muscats were superb, one house full of huge broad-shouldered tapering bunches surpassing anything of the kind I have ever seen. Well-filled plant houses also well rewarded me even for the hasty glance that I could only afford them, for evening was drawing on apace, and the train which I hoped to catch at Forest Row would soon be due—that, however, I was able to dispense with by Mr. Jenks's kindness in driving me back to the old forest again, and thus bringing my day's stroll to a pleasant close.—EDWARD LUCKHURST.

A DAY AT SLOUGH.

"BUT, my dear, sir, you have come at the wrong time; why come now to see us?" This was the first question my genial host and old acquaintance Charles Turner asked as he welcomed me at his charming home the Royal Nurseries. I may reply by another question—When can anyone go at a wrong time to Slough? What season is there when you will not find much to interest you? Winter and summer, spring and autumn, there is always some strain of flowers in season which there may be seen to perfection. During my September visit Mr. Turner's gardens were looking exceedingly gay. All round the house there are beds of Geraniums, Lobelias, Petunias, and other pans, and some annuals were very attractive; these were *For u'cas*, some of which were semi-double. Then there was a very fine collection of Phloxes, which always interest me. The Cannas reminded me of Battersea Park, and the carpet bedding of the Crystal Palace. In one avenue I found a grand collection of Zinnias, and when I turned the corner I came upon a splendid collection of Dahlias. These occupied half an acre of ground, and consisted of show, bouquet, and Pompon varieties. Many of the varieties which I had admired at shows I found whole lines of here. Christopher Ridley, the finest formed Dahlia yet sent out by Mr. Turner, was magnificent, as were also several seedlings sent out by the Rev. Mr. Fellowes.

Mr. Turner showed me also a house 40 yards long filled with a grand collection of Bouvardias, and another with Tree Carnations, which are just now coming in. As for Geraniums there were many thousands, but my host intends to give up

some sorts. "It is no use growing tricolors now; bronzes are a little better, and zonals are only good under glass. Nothing now but carpet bedding and Cannas." Such is Mr. Turner's verdict, and he is the largest Geranium grower I know of.

In one corner of the nursery, in a sheltered spot near houses, are splendid specimens of *Chrysanthemums* 8 feet high, which are to be devoted to the production of large show blooms. In another we find two thousand pots of specimen Carnations.

As we wandered along we came on the giant Rose trees in pots which have won every first prize this year. They were in the open air, and a man was watering them with as much care as if they were in full bloom, for it does not do to leave off attending to these grand specimens for one single day in the whole year. When I visited Cheshunt Mr. Paul's giants were in a cool house, but the Slough specimens will not go into winter quarters so long as fine autumn weather continues. Not far from the Roses were the specimen Azaleas, but these are now under glass. Near this house was a structure devoted entirely to *Maréchal Niel* Rose—fine plants 8 feet high, which command a high price and a ready sale. And then we come on more thousands of Tree Carnations. "We want a million, my dear sir. We could sell any quantity." The specimen *Ivies* trained as pyramids were very fine.

Just prior to my visit they had a regular flood at Slough, consequently the Rose blooms were knocked to pieces, but I saw a grand collection of plants. Mr. Turner's seedling *Dean of Windsor* is a good perpetual. The only yellow Rose which has made a grand pot plant at Slough is *Céline Forestier*. *Maréchal Niel* has been tried over and over again to no purpose, and even *Marie Van Houtte*, which does so well with me, cannot be made to answer as a specimen Rose when grown in a pot. Several thousand Teas in pots looked the picture of health. The wood was well ripened and the growth luxuriant. I noticed six long beds filled with Pinks for forcing. These are taken first into a cold house, and gradually they are accustomed to the forcing house, and then do remarkably well.

Mr. Turner then had his carriage brought round and drove me to several nurseries which surround the town of Slough and belong to him. In one near Chalvey we found 15 acres, half of which was filled with stocks that have been budded this year. First came the *Manettis* which were budded on plants, then the *Manettis* budded on cuttings. "What is the difference?" someone may ask. Every difference, I answer. The cuttings of the *Manettis* are taken and inserted in March, and are then budded in August and September, so that one year is saved. The *Manetti* plants are rooted cuttings which have been planted a year. Then came seedling *Briars* and *Briar* cuttings. The latter are far the best, as they grow straight and are very easy to bud. The former are most troublesome to work. They have to be wiped with a cloth, and a man has to cut many suckers and branches away before he can set to work. "It is no end of a mistake to say that seedling *Briars* don't sucker," said Gaiter, the foreman; "they sucker worse than the *Manettis*, but the *Briar* cuttings are not nearly so bad."

In another nursery we find the standard Roses ready for sending out. These are certainly grand plants, and the wood is very well ripened. In another near the railroad we see the *Manettis*. Nearly all the Roses are growing in maiden soil, and Mr. Turner has about ten more acres waiting to be broken up.

Once more we get into the carriage and drive to Salt Hill, where, close to the famous Inn, Bothams, we find several acres of fruit trees and Japanese Conifers and other shrubs. "I am sorry we have not time to take you to Uxbridge. We have 30 acres there we should like to show you, but we must now go to luncheon." And I am bound to say that the luncheon was in keeping with the nursery, and that I found it an exceedingly nice finish to a charming day.

I hope to visit these nurseries again next summer in the height of the Rose season and please my friend, whose parting words were, "Next time come a little earlier; don't leave us to the last." And if I am alive and well he will not find many weeks in June pass over before he once more sees his gratified visitor—WYLD SAVAGE.

NOTES ON VILLA AND SUBURBAN GARDENING.

FRUIT TREES.—The harvesting of fruit might be considered one of the most enjoyable employments connected with a garden—it is the reward gained for several months of labour and care; but during the last two seasons the generality of the outdoor crops have been greatly below the average. In no case have the

general crops been heavy; we therefore have the more need to take the greater care of that which we have been fortunate enough to possess. The gathering of fruits must now be carried on expeditiously, handling them with great care, otherwise they will bruise and decay quickly.

A perfect knowledge of the variety and the time of its arriving at maturity is a great help to ascertain when any particular fruit is ready for gathering, but it may be taken as a rule, especially with early varieties, that when the fruit parts from the footstalk when lifted gently up by the hand it is ready for gathering. Later varieties which do not ripen until the winter or spring months do not part as freely from the trees, but should be gathered before sharp frost sets in—just as the leaves begin falling. Fruit should always be dry when gathered. The middle of the day and fine afternoons are generally the best times, as the majority of the mornings at this season of the year are often moist and foggy. As the fruit is gathered it should be carefully laid out singly and regularly, which order allows of the quicker and easier detection of decaying fruit, which will frequently be found after it has been gathered a few days.

There can be no better time in the whole season for making a selection of sorts. Those that have been gathered are fresh in the memories of all, and those that are still hanging can be easily judged, and a selection formed by actual experience of varieties that do best in any particular locality. But for those who contemplate additions, or planting new collections, we print a selection of sorts that are in most places good and constant bearers, the fruits also being good in quality. We further advise the planting of duplicates of a few good varieties which have gained favour in all parts of the country rather than a great number of shy-bearing varieties. Trees may be purchased trained as standards, bushes, or cordons. The two latter are the best for small gardens, but the first are indispensable for orchard planting.

Of dessert Apples, perhaps the *King of Pippins* should be chosen first, as it is a very good grower and a most abundant bearer. Earlier and one of our richest flavoured dessert Apples is *Irish Peach*, a medium-sized fruit, ripe during August. Early Harvest is a most vigorous grower and an abundant bearer, and ought to be even in the smallest collections. During the last two precarious seasons this variety has with us been heavily laden. Cox's Orange Pippin is another most desirable variety, as a rule a very heavy cropper and about equal in flavour to the *Ribston Pippin*. The fruit is very handsome and will keep a long time fit for use. With the qualities of the *Ribston Pippin* everyone is more or less acquainted, we therefore cannot omit it from our selection; and in addition for later supplies we shall add *Courtpendu-Flat*, a richly flavoured juicy variety and a valuable dessert Apple of the first quality.

Of kitchen Apples *Lord Suffield* is one of our greatest favourites for early supply. The fruit attains a very large size, and may be gathered from for use while very young. Its fault is its lightness and falling so much when cooked, yet, considering its constancy, earliness, and size there are few to surpass it. *Dumelow's Seedling*, or *Wellington*, is one of our most valuable late varieties, a good bearer, firm, and handsome in shape. *Cellini*, a very handsome and free-fruited variety, an excellent cooker, and when ripe passable for dessert. New *Hawthornden* is another desirable free-bearing variety, in use during the greater part of the winter. To complete our selection of six varieties we name *Emperor Alexander* and *Alfriston*, the first a well-known early variety, and the last a very late-keeping sort.

Pears.—*Jargonelle* and *Williams' Bon Chrétien* are two very early-bearing varieties and well known to everyone. *Louise Bonne* of Jersey is another long-established variety of splendid quality, succeeded by *Marie Louise*, a Pear of the highest merit. *Doyenné du Comice*, *Huyshe's Victoria*, *Buerré Diel*, *Beurré Sterckmans*, *Glou Morceau*, and *Joséphine de Malines* are all good, and will furnish a successional supply over a long period. If there is plenty of room *Catillac* or *Uvedale's St. Germain* may be planted for cooking Pears, but windfalls of any variety may be utilised for that purpose.

Some good Plums for dessert are *Green Gage*, *Transparent Gage*, *Jefferson's*, and *Coe's Golden Drop*; and for cooking, *Prince of Wales*, *Pond's Seedling*, *Victoria*, and *Washington*.

Black Tartarian, *May Duke*, *Elton*, and *Bigarreau Napoleon* are free-bearing Cherries for dessert, while two or more trees of *Morello* should be planted for kitchen use, and when well ripened they make very fair dessert fruit, being large, handsome, and keeping well into September. They are much in request for bottling purposes.

Three good Peaches for a wall are *Grosse Mignonne*, *Noblesse*, and *Bellegarde*; and good Nectarines are *Lord Napier*, *Violette Hâtive*, and *Balgowan*.

All fruit trees like a well-pulverised, enriched, and holding soil; therefore the ground should be deeply broken up at once for some distance around where it is intended to plant the trees, and left prepared until the trees arrive from the nursery, which if the orders are given at once will be as soon as the leaves have fallen off. The earlier in the autumn the trees are planted the better chance have they to emit fresh roots and become established before the

drought of the following spring or summer presses on them. Espaliers, pyramids, or cordons may be planted parallel with the kitchen garden walks, and from pyramids we have frequently seen the leading shoots trained to an arch over the principal paths, forming a pleasing avenue.

WORK FOR THE WEEK.

HARDY FRUIT GARDEN.

LATE Plums are very valuable. Autumn Compôte is in use at the end of September or October, Belle de Septembre follows in October, and Coe's Late Red succeeds. The best of all the late Plums for culinary purposes and for preserving is Wyedale, which usually is not ripe until the middle or end of October; it is very hardy, succeeding in cold localities. White and new large Bullace are not despicable for tarts in late October or early November. Yellow Damask, Imperial de Milan, Bonnet d'Evêque, Blue Impératrice, and Late Rivers are desirable late Plums for dessert. Coe's Golden Drop and Ickworth Impératrice will mostly be ripe now. They should be gathered when quite ripe, placing them singly upon the shelves of a light airy fruit room, where they will keep in condition for some time, some esteeming them most when somewhat shrivelled. Apples and Pears as they become ripe must be gathered carefully, as it is not possible for the fruit to keep if it be carelessly handled. The late gales have greatly injured the Apple crop. The only sorts that have borne anything like a crop this season with us are Keswick Codlin, Lord Suffield, Holland Pippin, Cockpit, Norfolk Bearer, Hunthouse, and Crimson Queen; and Northern Greening, Devonshire Quarrenden, King of the Pippins, and Cackle Pippin are the only dessert kinds with a fair crop. In a future issue we will name a good selection of fruits for autumn planting.

Strawberries.—Plants that were planted out during the summer from the pots in which they had been forced will be setting and swelling the autumn crop, and should be mulched with litter to keep the fruit clean and be netted over. If the autumn be fine they often afford acceptable fruit, which, however, is improved in quality when covered with glass. We have known good fruit obtained by taking up the most promising plants with balls and putting them in rich compost, placing them behind a north wall for a few days, eventually transferring them to a house with a temperature of 50° min., abundantly ventilated. If the plants only promise indifferently in the open for an autumn crop remove the trusses, and clear away all runners so as to afford the crowns every facility to obtain strength for next season's crop.

Watering Strawberries in pots for the coming forcing season must not be neglected; though plants in well-drained soil in the open ground do not suffer from continued rains, yet those in pots are seriously injured by continued needless waterings, especially those required for early forcing, still they must never be dust-dry. Any that have the soil very wet and remain so for a time without watering should have the drainage seen to, as worms or the material upon which the pots are placed choke the outlet, rendering the soil sodden, in which no plants will thrive. The crowns are often numerous in some kinds, especially Black Prince and Vicomtesse Héricart de Thury, a number of small crowns clustering round the central one. The small should be removed so soon as they can be laid hold of with the finger and thumb, leaving the centre or strongest crown. This will concentrate all the vigour of the plant into the chief crown, and though there will be fewer trusses of bloom there is no need to fear a deficiency of crop, and it is essential that a forced Strawberry be large and red.

FRUIT HOUSES.

Pines.—To maintain the sturdy healthful appearance of young growing stock free ventilation is necessary, maintaining the bottom heat about the roots at 80°, watering the plants whenever they require it, employing weak liquid manure occasionally, and avoiding the use of the syringe too frequently; merely sprinkling the paths, &c., morning and evening daily will suffice. Fire heat must be resorted to to maintain a night temperature of 65° to 60°. Newly potted plants should have a bottom heat of 90° to 95°, with a view to the roots speedily penetrating the fresh soil. Recently started suckers should, as soon as roots are plentifully made, be raised near the glass, it being essential that those intended to be wintered in small pots be brought on very gradually. Fruiting plants should have a night temperature of 70°; 80° to 90° during the day, closing at 85°. When the suckers started this autumn are well rooted they should be potted without delay, draining the pots well. Employ the fibry part only of turfy loam, and do not fear it up too fine, but use it in lumps proportionate to the size of the pots. The strongest plants may be transferred to the fruiting pots at once, the size of the pots being proportioned to the robustness of the kinds. Jamaica do well in 9 or 10-inch, Queens in 10 to 11-inch pots, Smooth-leaved Cayenne and similar kinds in 11 to 12-inch, and Providence in 13 or 14-inch pots, which will afford fruit of the largest size. Where smaller plants and fruit are the object aimed at, pots an inch or two less in diameter will answer. The plants not of a size fit for transferring to the fruiting pots should be shifted into 8-inch pots, in which they should be kept until spring and then be transferred to fruiting pots.

Figs.—All the trees in pots outdoors intended for early forcing should be examined to see if any require shifting into larger pots or top-dressing, which should be done before the leaves fall. Except in the case of young small trees it is not desirable to increase the size of the pots, but remove a few inches of soil from the bottom of the balls, cutting back the roots, and replacing the soil removed with fresh. The surface soil must also be removed, removing all the loose portion, and replace with the requisite fresh material, which should consist of turfy loam with about a tenth of old mortar rubbish or road scrapings added, and for the top-dressing a fourth of well-decomposed manure. After this give a good watering, and place the trees in an airy situation under cover before frost or heavy autumn rains set in. The second crop of Figs in the latest house will soon be all gathered, and the trees should be kept drier at the roots; but avoid extreme dryness, which is pernicious; keep the house cool and dry, ventilating fully except when frosts prevail. If any lifting or root-pruning be necessary it should be done as soon as the leaves fall.

FLOWER GARDEN.

Heavy rains, foggy nights, and chilly weather soon work the ruin of the floral display. It is high time to see to the safety of such plants that require preserving. Pelargoniums of the bronze, tricolor, and other variegated-leaved varieties winter very differently if frost-bitten. Suitable quarters should be a low span-roofed house in which the plants can be near the glass, have plenty of light, and a temperature of 45° to 50°. It is undesirable on account of the slow growth of many varieties to head them back; simply removing any crowded growth, and stripping them of the leaves, the remaining shoots may be left at full length with a view to a supply of early cuttings in spring. The green-leaved varieties are more hardy, but they do better taken up before they are much frosted, cutting them well back, the roots being shortened, and potted in pots no larger than to hold the roots. They flower more freely than young plants. To save room they may be cut back and placed rather closely in boxes. We do not save any but the one-year-old plants.

Where it is desirable to preserve the plants in the beds as long as possible some kind of light protecting material must be at hand to throw over them when needed. Succulents, such as Echeveria metallica, Kleinias, Pachyphytums, Sempervivum tabulaforme, and others of that class, are very liable from the vigour induced by planting out to be injured by frost. Either they must be lifted before frost or protected from it, otherwise they winter very badly. Those that have been recently propagated, as well as Coleuses, Iresines, and similar tender plants, should be placed under cover at once.

Hyacinths, Tulips, and other spring bulbs plant without delay. There is nothing like planting early, so as to admit of their becoming well rooted before winter. Many plant late and complain of the bloom, the fact being the bulbs have not a chance, besides the best are gone before the order is given. If manure is used bury it well down, not allowing it to come in contact with the bulbs.

Fill up the gaps in the mixed border caused by the decay of annuals with Brompton Stocks, Wallflowers, and other sweet or gay spring or early summer-flowering plants, transferring biennials to their flowering quarters. Press forward the planting of evergreen trees and shrubs, and so soon as the leaves fall off the young deciduous trees the trees may be planted with advantage, it being better done soon than when the autumn is advanced and the soil wet and cold. Grass appears not to cease growing, though fallen leaves mar its beauty. Keep the broom going if neatness be wanted and roll frequently, mowing at least once more. Walks will require to be frequently swept and well rolled.

PLANT HOUSES.

Greenhouse.—Show and fancy, also spotted and regal Pelargoniums that have been shaken out and repotted, and after that placed in cold frames or pits, should at once be moved into the house in which they are to be wintered. They are best in a house by themselves, elevated so that their tops will not be more than a couple of feet from the glass, and sufficiently far apart to allow the light to reach the lower leaves. When the shoots are 3 or 4 inches long they should be tied out. Afford no more water than to prevent the foliage flagging. If kept wet the plants go too much to leaf. Zonals that have been kept in comparatively small pots for winter flowering should be placed under cover at once in a dry airy pit for the present, where they may remain for a short time before required for flowering, when they should be removed to a light house and have a temperature by artificial means of 50°. Salvias must be housed before frost and have a temperature of 45° to 50°. If kept cold the flowers are liable to fall off. Bouvardias that have been planted out must be carefully lifted and potted, placing them in a cold pit, shading them from bright sun for a few days and sprinkling them overhead, afterwards removing them to a light position in a house with a temperature of 55° to 50°, and they will bloom through the winter. It is desirable to divide such plants as those into batches and introduce them to heat at intervals. Solanums that have been planted out should be lifted forthwith and potted in 6 or 7-inch pots. They do well in light turfy loam, placing them in frames at the north of a wall, keeping the

soil thoroughly wet, or they will lose their leaves. When the potting is recovered from they should be transferred to a light airy position in the greenhouse. Few plants are more ornamental than Solanums with their dark green foliage and orange-coloured fruit. Any Gladioluses that have not yet flowered will, if lifted carefully and potted in 6 or 7-inch pots, be found extremely useful for conservatory decoration. Late Fuchsias should have the seed pods removed as they go out of bloom, and if supplied with weak liquid manure they will continue flowering for some time to come. A few of the forwardest plants of *Daphne indica* may be placed in a house where they will receive a few degrees of extra warmth of 50° to 45°, and they will flower early and be very acceptable. Roman Hyacinths, Paper White and Double Roman Narcissus that were potted some weeks ago will be well rooted, and should, in quantity according to the requirements, be placed on shelves near the glass in a house with a temperature of 55° to 50°, and coming into flower shortly are very useful. This is the worst season for flowers. *Rogiera gratissima* is fine for this time of year; its white sweet flowers are useful for cutting. It does well in turfy loam, and requires a rather warm greenhouse temperature. Tree Carnations must be housed without delay, and to flower freely during the winter months must have plenty of light and a temperature of 50° by artificial means. Callas that have been planted out should be lifted and potted in 7 or 8-inch pots in rich turfy loam, and abundantly supplied with water. Some of the forwardest plants may be placed in a light house with a temperature of 55°, and they will flower early. Plants kept in an ordinary greenhouse temperature will not bloom until spring, but by introducing batches of plants at intervals to heat flowers will be had over a lengthened period. Pot any late-flowering plants of *Anemone japonica alba*, employing some rich compost, standing the plants at the north side of a wall for a few days, then remove them to the greenhouse or conservatory, where they will flower to a late period.

Roses in pots should have a warm situation—all the sun and air possible, with no more water than to maintain the foliage fresh, so that the wood may be thoroughly ripened. If there be any aphid dust with tobacco powder, or if mildew be present apply sulphur, so as to eradicate the parasite, or it will give much trouble after the plants are placed under glass. Some of the Teas will have a plentiful crop of buds in various stages of development. Those placed in a light, airy, cool house will afford buds and blooms to a late period, feeding with liquid manure.

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

ADDRESS (A Lover of Rose Shows).—Write to Mr. William Baker, Rose Mount House, Roebuck Lane, West Bromwich, who will endeavour to give you information on the subject of your query of last week.

TENANT GIVING NOTICE TO QUIT (A Sixteen-years Subscriber).—Notice must be given by the tenant six months previously to the expiration of the current year of tenancy, so as to expire at the same period of the year in which the tenant entered upon the premises.

EVERGREEN CLIMBER (Jacko).—The best evergreen for covering a greenhouse chimney is the common Irish Ivy.

POTTING ROSES (Idem).—Roses should be taken from the ground and placed in pots as soon as the leaves fall in autumn. The best compost is turfy loam rather heavy and enriched with a third part of very much decayed manure. Half a peck of bone dust to a large barrowful of soil would render it additionally and lastingly fertile. Drain the pots well, and protect the drainage from becoming choked with the soil by placing over the crocks a layer of clean fibre shaken from the turf. Protect the pots from frost by enveloping them in fern, straw, or similar material, assuming that the plants will remain outdoors for a time after being potted.

NORTHERN FLORISTS (A Cottage Gardener).—It was not stated in the report of Newcastle Show that the florists you name took any prizes at that Show.

FLOWERS FOR NORTH BORDER (Amateur).—Pansies, Polyanthus, and Auriculas would be suitable for a shaded border 15 inches in width in front of a low wall facing north. Of the above flowers many beautiful varieties may be obtained from seed, or named varieties can be purchased from florists. Provided the soil is good Pansies in such a position would flower nearly all through the summer.

CALCEOLARIAS DISEASED (R. T.).—The leaves sent were so dry that they were crushed almost to powder during transit. The flower is a *Rudbeckia*, also much shrivelled. The species cannot be determined by such an imperfect specimen and without any foliage.

CUCUMBER CYPRUS (G. Hawkins).—We consider your Cucumber an excellent one. It appears to be a true cross between Munro's Duke of Edinburgh and Tender-and-True, having the greatest resemblance to the former. It is a rich green in colour, has scarcely any neck, and is very heavy, crisp, and well flavoured. You are justified in esteeming it a valuable variety.

PASSION-FLOWER NOT FRUITING (E. A. W.).—Unless a Passion-Flower growing on an open wall or the side of a house has advantage of a sheltered position fully open to the sun it will not have any yellow seed vessels, but with such advantages and ample wall space it will produce them increasingly with advancing age.

DWARF IRISES (Idem).—There are so many really good varieties of dwarf Irises that a selection of the three best is more a matter for individual taste

than for our decision. We may, however, take the sweet-scented *reticulata* of a deep violet colour, blotched with golden yellow, and growing about 9 inches high; *persica*, also a fragrant variety, white blotched with purple and yellow; and the pale yellow *caucasica*, with white-margined foliage.

TOMATOES BLIGHTED (Idem).—Disease among Tomatoes cultivated in the open air is now of annual recurrence. The only remedy is to grow-on a few plants in pots early in spring so as to have most of the fruit set before turning the plants out in the open air; then, by high feeding, pinching, and pruning of lateral growth and full exposure of fruit to the sun most of it may be gathered before adverse weather sets in. A surprising number of fruits may be picked from half a dozen plants under high culture, quite enough to supply the wants of a tolerably large family.

OWN-ROOT ROSES (Berley Heath).—The instructions to which you refer for converting Roses worked on short Briars into Roses on their own roots should be carried out immediately the leaves fall from the plants in autumn.

VINE STEMS NEAR HOT-WATER PIPES (C. D.).—The Vine stems are much too near the hot-water pipes. They should be at least a foot from them. The pipes should be removed to a greater distance. Probably the deficiency of growth in some of the Vines is a result of a deficiency of water. It would be advisable to have the front wall arched and allow the roots to pass out as they certainly will, a proper border being made for them.

SOIL FOR RHODODENDRONS (Idem).—Peat is most suitable, but they thrive admirably in turfy loam with a liberal admixture of leaf soil. Indeed Rhododendrons grow well in most soils except those containing limestone and soils of a very poor sandy nature. Rhododendron *ponticum* var., and *R. catawbiense* vars. are most desirable for extensive planting. A few select late-flowering varieties are—*Scipio*, The Warrior, John Waterer, Toward, Faust, Lady Dorothy Nevill, Barclayanum, Archimedes, Jenny Lind, William Downing, Papilionaceum, Purity, Vandyke, Sir Thomas Acland, Lord Elgin, Michael Waterer, Neige et Cerise, Lady Lopes, Madame Miolan Carvalho, Atrorubineum, Alarm, and Charles Dickens.

FIRS FOR PLANTATION (Idem).—The Corsican Pine (*Pinus Laricio*), is the quickest grower of all; it with Scotch Fir and the Austrian Pine succeeds admirably in exposed situations. The Norway Spruce and White American Spruce also grow quickly.

PEAR TREES LUXURIANT (Idem).—The best way of checking their luxuriance and inducing fruitfulness is to root-prune the trees, which should be done as soon as the leaves have fallen. If the trees make much wood too many of the roots must not be severed, or the future growths of the trees will be seriously affected. Root-pruning requires to be done judiciously even by experienced hands.

FRUIT TREES FOR SMALL GARDEN (W. X. Y.).—*Dessert Apples*: Kerry Pippin, Cox's Orange Pippin, Margil, and Scarlet Nonpareil. *Kitchen Apples*: Keswick Codlin, Cox's Pomona, Cellini, Warner's King, and Hanwell Soring. *Pears*: Williams' Bon Chrétien, Fondante d'Autonne, Doyenné du Comice, Winter Nelis, and Bergamotte Espéren. *Plums*: Early Rivers, Victoria, Autumn Beauty, Green Gage, and Cox's Golden Drop. *Cherries*: Empress Eugénie, Governor Wood, Kentish, and Morello. *Figs*: Brown Turkey and Brunswick. *Peaches*: Early Rivers, Grosse Mignonne, Dr. Hogg, and Barrington. *Nectarines*: Lord Napier, Stanwick Elrige, Pittmaster Orange, and Pine Apple. *Apricots*: Kaisha and Peach. *Currants*: Knight's Large Red, White Dutch, and Black Naples. *Raspberries*: Prince of Wales. *Gooseberries*: Early Sulphur, Pittmaster Green Gage, Warrington, Ironmonger, and Red Champagne. *Strawberries*: Garibaldi, President, Dr. Hogg, and Frogmore Late Pine.

CLIMBING PLANTS FOR COVERING A HOUSE (Idem).—*Lonicera brachy-poda*, *Ampelopsis Veitchii*, *Berberidopsis corallina*, *Ceanothus azureus*, *Escalonia macrantha*, and *Jasminum officinale*. There are a host of other climbers—Roses, Clematises, several more Honeysuckles, &c. If you want berry-bearing climbers for winter take *Cotoneaster microphylla*, C. Simonsii, and *Crataegus pyracantha* with brilliant orange berries. The proposed arrangement of the garden is good. As you are fond of hardy flowers let the 8 feet border in front of the Privet hedge be specially devoted to them. A few groups of shrubs well placed on either side of the lawn will make a pretty vista from the house to the croquet ground, and flower beds may be made on the lawn, but we should prefer the turf, with flowers fringing the shrubs. The best of all shrubs for planting beneath the large Elms are Hollies and Rhododendrons. When once established they will hold their own against the roots of the large trees, and no shrubs are more ornamental.

WINTER PLANTS FOR RUSTIC BASKETS (Basket).—There are many ways of making such basket beds ornamental in autumn, winter, and spring. They may be planted with bulbs, such as Crocuses, Snowdrops, Hyacinths, Tulips, and Scillas, with a surface planting of hardy succulents; but we prefer a bolder style of treatment, and would have an outer row of well-matched plants of *Erica Fœxii* kept a little way apart and 3 or 4 inches from the edge, so as to afford space for an intertwining chain of the bright silvery-leaved *Eucynon radicans variegatus*, inside which should come a ring of *Erica carnea*, already bristling with flower buds, and a central mass of *Iris fœtidissima*, with its elegant flag-like foliage and pendant pods of scarlet berries, which are in full beauty throughout winter. If you cannot readily obtain those plants, plant the vases as you suggest, intermingling with the shrubs the bulbs named.

CLIMBING DEVONIENSIS ROSE (Holly Lodge).—We advise you to plant the fine plant you have obtained of this Rose. It produces charming blooms, but not so profusely and continuously as some other varieties. In the list to which you refer we were limited to particular colours and plants to be grown for a special purpose.

SEEDLING PEACH (D. Morris).—The fruit to which you refer has not arrived.

BELLADONNA LILY NOT FLOWERING (J. W. S.).—We can only account for this plant, also *Crinum longifolium*, *Sternbergia lutea*, and *Agapanthus*, not flowering through their not having attained sufficient strength. We presume they are planted out on a warm border, and abundantly supplied with water during growth, especially the evergreen *Crinum* and *Agapanthus*, the latter having protection in severe weather.

APPLES AND PEARS FOR ORCHARD (J. W.).—*Apples*: Irish Peach, Worcester Pearmain, Cox's Orange Pippin, Duchess of Oldenburg, Emperor Alexander, Cox's Pomona, Dumelow's Seedling, Cellini, and Lady Henniker. *Plums*: Early Rivers (Prolific), Gisborne's, Prince Englebert, Victoria, and Wyedale. *Pears*: Jargonelle, Beurré de Capiaumont, Williams' Bon Chrétien, Louise Bonne de Jersey, and Marie Louise.

PROPAGATING PILEA MUSCOSA (Paddle).—It is propagated by cuttings, which strike freely at any time of the year in gentle heat or in a stove, keeping them moist.

RAISING PRIMULA JAPONICA FROM SEED (Idem).—We experience no difficulty, merely sowing in pans so soon as the seed is ripe, just covering it with fine soil and keeping it regularly moist. It is perfectly hardy; seed vegetates as freely as *Polyanthus* seed if sown so soon as ripe on a shady border. We presume your seed has been old, which does not vegetate freely, often not until a year after sowing. Procure plants, and you will soon have a stock by saving the seed and sowing as advised.

DAHLIA PARAGON.—"W. B." says that is not new, for he has grown one so named for nearly fifty years. They may not be the same varieties notwithstanding. We have known flowers totally distinct called by the same name in different localities. Send us a bloom by post.

GRAFTING (R. Bickum).—"Fruit Gardening for the Many," published at our office, contains directions for grafting. You can have it free by post if you enclose six postage stamps with your full directions. A small pamphlet by Mr. D. T. Fish, entitled "Grafting and Budding Fruit Trees," is also published at the *Bazaar* office, price 1s.

PRUNING TACSONIA (Idem).—Cut it back to 2 feet in spring, and secure strong shoots from near the base for covering the wall, and there will then be no difficulty in securing shoots for the roof.

LOBELIAS FAILING (W. G.).—They fail either from poverty of soil, a deficiency of water, or excessive rains. We find that by selecting the best-habited plants and deepest-coloured flowers for seed that the seedlings come quite true, and usually grow more freely than cuttings. Lobelias have not done well this year. The drought in July caused a cessation from growth and the production of seed, and the showers of August caused many plants to decay. They are not wanted for carpet beds, and are not now employed in such beds in any of the London parks.

WINTERING ALTERNANTHERA AMENA (A Five-years Subscriber).—It should be taken up before frost, potted, and kept in a temperature of 55° to 50°, with sufficient water to keep the foliage from flagging. The tuberous-rooted Begonias should be kept with the soil just moist, inclining to dryness during the winter, in a cool house; but if space be a consideration they may be taken from the soil after the leaves and stems fall, and stored away in damp sand in a cool place safe from frost.

GROWING VINES AND FIGS IN POTS (Idem).—There is no objection to your growing Vines in pots on one side of the house and Fig trees in pots on the other, the latter not having the Vines directly over them, confining the Vines to the south side of the house.

NAME OF TREE (W. D. H.).—*Taxodium distichum*, a native of North America, from whence it was introduced in 1640.

NAMES OF FRUITS (M. S. K.).—1, Hollandbury; 2, Dumelow's Seedling; 3, not known; 4, Lucombe's Seedling; 5, Devonshire Buckland; 6, Robinson's Pippin. (*Shrewsbury Hall*).—1, not known; 2 and 3, Marie Louise; 4, Comte de Flandre. (*T. W.*).—1 and 2, Royal Russet; 3, Sykehouse Russet; 4, Ashmead's Kernel; 5, Winter Greening; 6, Sweeny Nonpareil. (*W. G.*).—1, Either Northern Greening or Lemon Pippin, we think it is the former; 2, Baldwin; 3, Russet Table Pearmain; 4, not known; 5, Elford Pippin; 6, Northern Spy. (*Juvenile*).—1, Barcelona Pearmain; 2, Beauty of Kent; 3, Selwood's Reineette. (*A. G. S.*).—A, not known; B, Dumelow's Seedling; C, Jersey Gratioli; D, decayed, but probably Fondante d'Automne; E, Cockle Pippin; F, Brownlee's Russet. (*J. R. P.*).—The green one is Ori's; the yellow one Manks Codlin. (*E.*).—We cannot possibly name forty specimens. Our rule is to name six only, and we cannot go beyond that number. *Pears*: 2, Beurre diel; 3, Duchesse d'Angoulême. *Apples*: 123, Gloria Mundi; 133, Dumelow's Seedling; 120, Blenheim Pippin; 122, Cellini.

NAMES OF PLANTS (W. H. F. B.).—We cannot identify plants from their leaves only. (*Lancashire*).—1, *Rivina levis*; the Ferns are without spores; 4 seems a variety of *Peris cretica*. (*Norfolk*).—1, *Polygonum cuspidatum*; 2, *Spiraea Douglasi*. (*M. D. D.*).—A Vine of some kind, but the specimen is insufficient. (*R. T.*).—*Boussingaultia baselloides*. (*A. B. C.*).—Specimen much too young. (*C. T.*).—*Lastrea sp.* (*E. E. E.*).—*Genista monosperma*. (*A Subscriber*).—*Amelanchier Botryapium*.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

THE CULTIVATION OF WHEAT.

(Continued from page 250.)

THE preparation of light soils for the wheat crop now demands our attention, and under the designation of light land we must include gravelly, sandy, and thin chalk soils. The two first-named soils will require different management from the last-named, and we will therefore refer to the preparation of the two first named. The usual course adopted is the four-course—first, roots; second, Lent corn; third, clover and grass; fourth, wheat. The wheat will therefore be sown after one ploughing-out of clover lea, except in case of failure of the clover, in which case the land would be sown with an early sort of pea, so that the land may be nicely prepared for wheat by scarifying before laying out the dung. It is best to lay-out the dung upon the clover lea, and dress the peas eddish with 3 cwt. of Peruvian guano sown broadcast, and harrowed-in just before the wheat is drilled. Let us suppose, however, that the clover lea is perfect. Upon these soils we do not wish to sow the wheat very early because it is usual to carry a large flock of sheep, and although it may be right on the loamy land to plough-in all the flag or late grass which may arise after harvest, yet upon these light

soils it is advisable to feed the clover lea bare, and instead of looking to the vegetable manure where the late growth is ploughed under, it is preferable to look to the manure left by stock after feeding. In this light land, too, the clover ploughed-in would make it too light and more subject to depredation by the wireworm and the plants thrown-out by frost, whereas if fed close before ploughing the land would settle down firm and give a better seed-bed for the wheat. In this land the season for ploughing and sowing may often be deferred until the latest period, say from November 14th to the 10th of December, for upon such land if it is liberally manured and the young plant just shows above ground before Christmas it is early enough. It is not subject to the growth of weeds when drilled thus late. Ploughing and pressing must be the rule, and sometimes when the land is very dry Crosskill's heavy or the Cambridge ring-roller may be used before harrowing and preparing for the drill. When sown thus late from two and a half to three bushels of seed per acre will be required, for it is sure to suffer more or less from larks, rooks, &c., which prey upon the grain as soon as it germinates. The distance between the rows is of some consequence, because upon sandy land and also upon gravelly land some annual weeds such as the poppy, the marigold, &c., will make their appearance in the spring, when it will be necessary to both horse and hand-hoe in some seasons.

We will suppose that the clover lea has been dunged, but if not there is no better dressing than 3 cwt. per acre of Peruvian guano sown after the presser. It will then be properly buried, and deep enough by the action of the harrows to benefit the wheat plant to the fullest extent without feeding the surface weeds. It often happens that the best guano contains portions and lumps as hard as rock; but we get this broken at the bone mill, because when the men at the home farm are set to break it the work is often badly done, and one lump which ought to dress half a rod of ground will destroy all vegetation within reach of its influence, on account of the concentrated action of the ammonia it contains. The sorts of wheat adapted to light land will vary according to the climate, because we have some of these light lands in almost every county or district. In the eastern and southern counties white wheat will do well, such as Morton's White and several sorts of white wheat propagated and grown as Hallett's Pedigree; but in the western, northern, and some midland districts the coarser red or brown varieties answer best, such as Golden Drop, Browick, Red American, or Spalding, together with some of the Red Pedigree sorts.

In preparing yard dung for application to these light lands it is a good plan to have a portion of clay or strong loam mixed as compost. This is often done by making a bottom for the manure heap and covering also of clay, &c., so that when turned-up together it makes a very beneficial compost for light land. But the best of all ways in making such a compost is to have the strong loam used as a bottom for the farmyard, and also for all pens where either horses, cattle, or pigs are kept. In this way the whole of the manure is obtained and retained in admixture ready to go upon the land when wanted. We have on various home farms used with the best advantage in this way upwards of 150 cartloads of earth in a year. We would further remark that these dry soils do not require to be early ploughed, for unlike heavy land they are benefited and consolidated by the heavy autumnal rains peculiar to our climate previous to being ploughed.

The treatment of dry chalk soils forms the last division of our subject, and it will be found to some extent to differ from the cultivation before described for other lands. Still upon good substantial loams resting on chalk where the climate and aspect are good, the management will be very similar to that before described for dry loams. Yet upon the chalk hill farms in various counties where climatic influence is adverse, and which we now propose to consider, is somewhat peculiar. Home farms are often of small extent, particularly of arable land, but we know various farms which are attached to park lands of considerable extent and capable of carrying a flock of breeding ewes numbering

from five to six hundred. It used to be the plan on such holdings not to sow wheat oftener than once in six or seven years, and even then producing only a very moderate crop. Since the extended use of artificial manures, however, upon these high and dry soils, root-cultivation has so much improved and increased that rotations like the four-course have been found to answer almost as well as upon some of the better lands more favourably situated. The culture for wheat is, however, different, and where large flocks of sheep are kept eating oil cake and corn upon outlying lands it is very encouraging to know that oil cake and artificial manures answer a better purpose and return a better percentage upon the outlay than some more naturally fertile soils. Wheat not only succeeds clover lea, but also turnips fed-off by sheep. In fact, the sheep are the chief vehicle for manure on this hill land, being close folded on the clover leas before ploughing and pressing; the dung made by the horses, cattle, and pigs maintained at the homestead being laid upon the land nearest to the home farm buildings.

The clover lea should be ploughed early—August is none too soon—in order that the land may have time to settle and become firm and stale, and thus prevent the wheat plant being thrown out and becoming root-true, as it is very apt to do upon these loose and hollow soils. The time of sowing likewise should be earlier than upon any before-named soils to prevent blight at harvest. We have noticed especially two different systems, carried out side by side upon similar soil on a chalk hill farm, one farmer sowing early, sometimes during the month of September, the other sowing the last week in October or early in November, and we have seen the early-sown produce capital wheat both in quantity and quality, whereas the later-sown gave a full bulk of straw, but was seriously blighted and with defective grain. The system of maintaining large flocks of sheep, together with other circumstances, induces farmers to change or alternate the clovers, taking half the lain of broad clover and half in trefoil, to be reversed in the next course. In case of the trefoil it is either cut for lamb hay or fed early with sheep. In either case it is ploughed up at or before midsummer, and then sown with turnips or rape, or both in admixture, all the manure intended for the wheat crop being applied before the turnips, &c., are sown, so that as much of root food as possible should be obtained for sheep, and thus increase the manure for wheat. The land, however, should be carefully ploughed and pressed for turnips, which are often destroyed by wireworm upon this hollow soil. After the turnips, &c., have been fed off by sheep it is a very common practice to plough the land before sowing the wheat; but we prefer to scarify only, in order that the land may have the full advantage of the treading of the sheep whilst feeding off the turnips, so desirable upon this chalk soil. Sometimes we have known wheat take very well when it was not intended to be drilled by sowing before the plough, the ploughing being done very shallow and fleet, which is sure to bury the seed well, and also it prevents the plants being thrown out in the winter. The great point in successful cultivation upon these light and loose soils, whether the seed has been drilled or ploughed-in or sown after the presser, is that the land should be trodden by sheep immediately after sowing, the plan being to carefully drive them in regular courses across the field, and when the weather is very dry they may with great advantage be driven over the second time in the opposite direction to the first drift. This necessary work is usually done by the use of dry sheep, such as tegs or lambs; but upon those farms where no dry stock are kept the in-lamb ewes may be used for the purpose, except that more care is required by driving them steadily without worrying by dogs. In concluding this subject we have one general remark to make, which will apply with great force upon all the white land chalk-hill farms—that in cultivating for all crops the scarifier only should be used either by steam or horse power, except in the case of clover or saintfoin leas, which will of course require to be ploughed and pressed, with the surface roots well tucked under in the act of ploughing with the skim coulter.

WORK ON THE HOME FARM.

Horse Labour.—Now the seed time for wheat is so near at hand horse labour will be employed in different ways in preparing the land for wheat. Where the early turnips have been fed off on the heavy and loamy soils the ploughing, drilling, harrowing, &c., will be going on. Upon the lea ground the dung will now be drawn out, spread and ploughed and pressed. Upon light soils with full-sized upstanding horses this work may be done with two animals attached to a double furrow plough. This will be good economy, with the presser following, being drawn by one or two horses according to the weight of the presser. In some cases if the weather is dry it will be necessary to roll with the ring roller as well as harrow the land before drilling, because the land cannot be made too close and firm. The carriage of recently thrashed wheat or barley to the mill or the railway station will employ some of the horses upon the home farm. Some horses will be required in drawing coals and water when thrashing corn is going on of ricks made in the fields. Some horses will also be employed in harrowing, dragging, &c., upon the land recently scarified either by steam or horse power, so that the grass and weeds which may

have been brought to the surface may be got together by the chain harrow and then carted away to heap, there to rot for future use in various ways. The horses will then have finished all the work required upon the autumn fallows, except the fallow ploughing to be done after the wheat seeding is completed. The odd horses will find employment by carting hurdles, &c., for the shepherd, in carting early turnips to the homestead for the fattening cattle, also carting vetches and oats where they have been grown in succession for horses and dairy cows, as the grass if not gone is becoming stale on the pastures. The clovers, too, are affording a cutting this year in many cases where sown in the wheat and oats, and this may be continued in use until the frosts commence without injury to the horses, especially if they are allowed a full allowance of corn with some extra chaff.

Hand Labour is still various. Hedges must be finished trimming; the dung must be spread upon the wheat land; men must assist in finishing off the straw ricks and carting away the hulls where thrashing has been done; straw ricks for sale or for fodder should be carefully thatched. It is now too late for hoeing root crops, but in consequence of a long succession of stormy weather there are many weeds. These should be pulled by hand by women if they are to be had for work, otherwise by men. At this time many changes of farm servants will be taking place, such as teamsmen and shepherds as well as casual labourers; and the matter of hiring will require great care and discrimination on the part of managers of home farms in the present temper and disposition of the labouring classes. Even in those cases where there are cottages to accommodate all the men required upon the home farm, yet men of good character only must be engaged; and in case they have no strong working lads in their families it is well where there is room in the cottages to arrange with them to lodge young working fellows which may be engaged for working upon the farm, and these should be hired by the year in order to insure a sufficient staff of workers at the most important times of the year. This is an important matter, too, for the young men themselves, as they may learn all kinds of farm work and avoid a roaming and roving habit of life when engaged by the year.

CAMBRIDGE ORNITHOLOGICAL SOCIETY.

SEING in a contemporary that there will be no Oxford Poultry Show this year, it may interest some of your readers to know that an Exhibition of Poultry, Pigeons, Rabbits, and Cage Birds is intended to be held in the New Corn Exchange at Cambridge, under the auspices of the Cambridge Ornithological Society, the proposed date being November 6th and 7th, prizes being for open competition. The New Corn Exchange in Cambridge is one of the most evenly lighted and best suited buildings in England for the purpose, having a glass roof with unobstructed light from windows on both sides, and is well heated by hot water. Cambridge in itself is one of the most convenient of towns for railway accommodation. The Great Northern, the Great Eastern, the London and North-Western, and the Midland Railway Companies all have a station. Hampers can be booked through to Cambridge from all parts, and each company will deliver free of extra charge to the Corn Exchange, and have booking offices within 200 yards of the building where they receive parcels or hampers. The telegraph and post offices are within 300 yards. It is to be hoped all fanciers will do their utmost to assist the working Committee to make this undertaking a success. All who wish to encourage the undertaking should at once correspond with the Secretary, Mr. R. Peters, jun., Accountant, 30, Bridge Street, Cambridge, as there is but little time to get through the requisite arrangements.—FRANK J. R. NUNN, *Clare House, Chesterton Road, Cambridge.*

THE HEMEL HEMPSTEAD POULTRY SHOW.

HEMEL HEMPSTEAD was *en fête* on Thursday and Friday. We never remember having seen the whole population of any place so thoroughly interested in a show. The days for it were judiciously selected, the first being market day, the second the day of the annual flower Show; we believe, too, that it was the first poultry Show that had ever been held in the neighbourhood. This added to the fact that the famous contest of incubators had for twenty-one days been going on in the town, and terminated at noon on the first day of the Show, created an extraordinary amount of interest in the affair. The weather was lovely, and the streets were bright with flags, arches, and Venetian poles. Perhaps not the least attraction was the electric light; we were not ourselves able to stay to see its effect, but saw full preparations for it. The history of its use there is interesting as showing the extraordinary care with which every arrangement for this Show was conducted. It was originally stated in the schedule that the birds would not be shown by gas light. This arrangement we cordially approve, as we have known great damage done to birds by gas. Meanwhile the energy with which the scheme was carried out caused greater interest to be taken in the matter than could possibly have been anticipated. Many whose daily occupation would not

allow them to get a sight of the Show wished to do so, and begged to be allowed an evening view. How could this possibly be managed without gas? The enterprising Committee solved the difficulty by ordering at great cost the lighting of the buildings by the electric light.

We confess to having become rather tired of the sameness of poultry shows, the novel features of this one were therefore particularly pleasing to us. We feel sure that other committees will take hints from it. The exhibition of cockerels and pullets in pairs yet in separate pens was a decided success. It obviates all scuffling in the pen, and enables a judge to have a fair look at both birds apart. But we must proceed to particulars. The major portion of the birds were shown in the Drill Hall, but the entries so far exceeded expectation that a marquee annex was added communicating with the hall.

The local classes came first, and very good they were for local classes. The special prize of six guineas went to a wonderful pair of *Dorkings*, the hen not very good in feet, still such a pair as might win at the Crystal Palace. The first pair of *Brahmas*, too (Lights), must have been very near for this honour. The winning *Crève* cock, too, struck us as magnificent, but his partner was poor in crest.

In the open classes *Dorkings* came first, as they should. All the prizes went to Darks, the Silver-Greys shown not being first-rate. The cockerel in the first pen and the pullet in the second were wonderful birds. The third-prize pair far exceeded all others in size, but are lighter in colour than the now fashionable birds, and so many judges would have preferred Mr. Burnell's highly commended pair. *Cochins* were not all round a fine class, though the winners were excellent. First were a pair of Buffs, the cockerel immense and the pullet beautiful in shape and even colouring; second some of the most sheeny green Blacks we have ever seen; third good, a shapely White. A pair of Partridge, the pullet of which was superb, were disqualified on account of the singular state of the cockerel's wing. The whole of the secondary wing feathers were either absent or very short, and the latter were obviously coming perfectly twisted, and would when full grown cause the wing to be deformed. *Brahmas* were not well matched as a class, there being several ill-assorted pens. The winners were all good. First were Darks, too heavily hooked, but the pullet a beauty of the softest Silver-Grey hue; second and third were Light, both good in quality. *Game*.—First and second were capital Piles; the cockerel in the second pen was undubbed; Black Reds were third. *Polands* were a very good class of eighteen entries, and included all three varieties. A very superior pair of Golden took first prize. *Hamburghs* were a good class, though many were out of condition. *Langshans* had eight entries. We hardly know what to say of them. We know that the Judges did their best to make their awards according to the standard of the Langshan fanciers, but rumour said that the third-prize pair were nearly related to some well known Black Cochins. *Sultans* were a very poor lot, several hens being hump-backed. The Judge withheld first prize. The second pair were generally by far the best, though the pullet showed a tinge of colour in the breast. They were five-clawed, as were, we think, the original lot imported by Miss Watts; all the others shown had four claws. *Spanish* were, as a class, rather behind, though the first pair were generally good, but wanting a little in drop. *Houdans*.—The winners were all good; the rest not remarkable. In *Crèves* again the prize birds were all good, though several otherwise fine cockerels in this class were inclined to have wry tails. *La Flèche* were a poor lot. *Leghorns* multiply and improve. There were eighteen entries, and few bad birds. First and second were beautiful Whites, very free from any yellow tinge; third capital Browns. Mr. Bradbury's birds were penned after the awards were made, but just in time for a high commendation to be given to a good Brown pair. *Andalusians* were decidedly good. The first and second cockerels were both splendid birds, the general carriage of the first being rather the best, and their make well worthy of them. The pair of first winners at the Staffordshire Show had to be content with a high commendation. Any other Variety were not a very large or remarkable class. First were a fine pair of Malays, second Silkie, and third Dominiques. The Selling Class was for single birds of either sex, a good Spanish cockerel winning first; a bargain for someone.

Time failed us to do justice to the *Pigeons*. We saw in a hasty glance that in Pouters some of the best known winners were beaten. Jacobins were a large and capital class, an excellent Red first. Fantails were in singularly good condition for the time of year. First had a wonderfully round tail and fine carriage. In Turbits a well-known Yellow and Blue were first and second, Mr. Raper third with a Black clean in thighs. We fancied all his birds were sold the other day at Stevens'. In the variety class an Agate Tumbler and a Blue Runt were first and second.

The visitors to the Show seemed many, and included a number of leading fanciers, who were the guests of Mr. Peel at Abbots Hill. It seemed to us that the wonderful management of the Show, down to the minutest details, was firstly owing to the energy and generalship of the Rev. H. R. Peel, and secondly to the fact that the Committee were a real working Committee.

We must not omit to mention that the £25 prize for the most successful incubator was won by Messrs. Christy & Co. of Fenchurch Street, whose two machines hatched an extraordinary number of chickens. A report of the incubators and their workings will be given elsewhere, so we will not at present say more about them.

The staff of Judges was large for the numbers of entries. Their labours were thus divided:—The Rev. George Raynor took the local classes of poultry; Mr. O. E. Cresswell the Dorkings, Cochins, Sultans, Leghorns, Andalusians, Any other variety, and Selling class; Mr. M. Leno the Brahmas, Game, Polands, Hamburghs, Langshans, Spanish, Houdans, Crèves, and La Flèche; Mr. F. Esquilant the Pigeons. We must not forget to mention that the Show was held under the patronage and rules of the Poultry Club.

INCUBATORS AT HEMEL HEMPSTEAD.

THE first competition of incubators ever held terminated at twelve o'clock on the 26th ult. at Hemel Hempstead. There were a few incubators exhibited at the Dairy Show at the Agricultural Hall a year ago, but there was no competitive trial, the incubators being brought in just before the show opened, and exhibited in working order or not at the option of the inventor. At Hemel Hempstead, on the contrary, the incubators were started three weeks before the date of the poultry show, and during that time were under the sole care of a manager appointed by the Committee. There have been some opinions expressed that the owners should have had the option of managing their own machines, but we think nothing could be fairer than the conditions under which the trial was held.

There is no doubt that some of the more complicated machines might possibly have furnished better results had they been in charge of their inventors, but we think that an incubator to be of any practical use should be sufficiently simple to be worked by any ordinarily intelligent person. We may congratulate the Committee on having had such a place as the Waterworks at their disposal, as it was in every way fitted for such a trial, and also on having been able to place the incubators under the care of such a competent manager as Mr. Twig, who, being an engineer by profession, was especially suited to take charge of them.

Seven incubators were entered for competition—one by M. Voittellier, and two each by Messrs. Christy, Penman, and Boyle. One of each of the machines invented by Messrs. Penman and Boyle was worked by hot water heated by gas and the other by lamp. Messrs. Christy's and Voittellier's machines were worked simply by pouring in hot water at stated intervals. One of Mr. Christy's incubators was the most successful, having hatched by twelve o'clock, September 26th (the time fixed for the conclusion of the trial), thirty-four out of forty-five fertile eggs, or about 75 per cent. Mr. Christy's second machine came next with 44 per cent. The only other successful exhibitor was Mr. Boyle, who hatched a small number in his gas incubator. In our opinion the total failure of Mr. Penman's and the partial failure of Mr. Boyle's machines were owing to the regulators being of such a complicated nature that the true working of every part could not always be depended on. M. Voittellier's failure we believe was owing to the directions given for the management of his machines, which were very scanty, and we think rather doubtful on one or two points.

With regard to the winning machine it was certainly as simple in theory as possible, but we think the trouble of procuring the necessary quantity of boiling water twice a day for several weeks will prevent its being of practical use to many who have not the time and accommodation necessary at their disposal. In conclusion, we wish to tender our congratulations to the Hemel Hempstead Committee on the success of the first attempt at an incubator competition, and trust we may soon have another contest under similar conditions, as we think a more perfect machine can be introduced than any yet exhibited.—R. E. HORSFALL.

SILVER-GREY DORKINGS.—May I once more appeal through your columns to the fanciers of Silver-Grey Dorkings for subscriptions towards a cup for the best adult cock or hen of the breed at the forthcoming Crystal Palace Show? I have already had 21s. given me by Mr. T. C. Burnell. My address is for the present —O. E. CRESSWELL, Windlesham, Bagshot, Surrey.

VARIETIES.

"THE agricultural returns for Great Britain," writes Mr. James Caird to the *Times*, "show a small increase over last year in wheat and barley and a decrease in oats. The extent under wheat has increased by 50,000 acres. Estimating Ireland at a little over last year the total area of wheat in the United Kingdom will be nearly 3,400,000 acres. From the general appearance of the crop on the ground, and trials by thrashing already made in various parts of the country, there can be no doubt that the wheat crop now being harvested is a full average, and the best

we have had for some years. The increased average and the additional produce will afford us 11,500,000 qrs. for consumption. We shall require 13,000,000 qrs. more, for which we must look to our foreign commerce and to our Indian and colonial supplies. During the past harvest year, now drawing to a close, we shall have imported upwards of 15,000,000 qrs. of wheat and flour. This is the largest import we have ever received; it has kept the price reasonably moderate, and the surplus has come mainly from the United States. The latest advices from that quarter show that, while the great crop of 1877 is not yet exhausted, the prospect of the present crop is much less satisfactory. In France the wheat crop is believed to be below an average, so that we are likely to meet our nearest neighbours in the market as buyers rather than sellers. There is thus much probability of the present price being maintained, and, perhaps, slightly increased, but there will be no scarcity."

— MR. JOSEPH ALEXANDER, Imlick, Carrigans, Londonderry, writing to the *Irish Farmers' Gazette* under date 26th August, 1878, describes potatoes as being "a grand crop; nothing like it so far as appearances yet go since 1845, and ground being in so dry a state a large portion of the crop is likely to keep sound. To give a comparison of this year's crop with that of 1877 the statement might seem somewhat exaggerated. Take a Cunningham acre, yielding four tons in 1877, and this season yielding twelve tons: the nutritive value of one ton this year being equal to that of two tons of 1877, would make one acre of 1878 equal to six acres of 1877. This may seem rather startling at first sight, but a little thought of those who have had the experience will convince them that the comparison of the two seasons is doing full justice to 1877. Of course much depends on the next few weeks of this year." Very much: and we almost fear that Mr. Alexander is over-sanguine in his estimate, but hope not.

EXAMINATION OF STOCKS.

Of all the months of the year September is the most suitable for a thorough examination of stock hives, the best month to finish feeding and let the bees settle down to the quiet and rest of winter. It is also a good time to examine hives with a view to ascertain if they are quite clean and healthy and free from foul brood. Generally speaking, hives then have hatched out all healthy brood, and if some cells remain with lids to them we have good reason to suspect the existence of foul brood. Almost all diseased and foul brood is sealed up—i.e., covered up with lids, which are rather scooped or concave in shape, much resembling the lids of honey cells.

Last week I examined all my stocks, when I found seven of them rather short of bees and one affected with foul brood—a swarm of last year. On discovering the foul brood the hive was condemned, the bees driven into a small empty hive, which will be fed into a stock at an expense of 3s. only, for the swarm is small. The hive yielded to-day 6 or 8 lbs. of good honey, which will be sold at 1s. 4d. per pound. The bees were shaken out of the affected hive by giving it three good thumps on the board, and then partly covered with the small hive. The bees outside ran into the hive. The honey was speedily taken and run into a jar in one of the vineries. Afterwards I saw the queen and three bees at the bottom of the hive slightly daubed with honey. She was at once carried to the swarm, which was in a state of great commotion without her. I placed her on the board at the door of the hive. In an instant of time the bees that first saw her gave the signal and the sound that the lost one was found, and they began to be merry.

But what about the seven hives short of bees? Well, I wrote to Mr. Addey in Lincolnshire to send 12 lbs. more of condemned bees to strengthen them (I had received twenty swarms, 100 lbs., of him to feed into stocks already). He sent 16 lbs. of bees in three swarms or separate lots. They arrived late in the evening. Having come a long way by rail they were hungry and jaded. They were taken by candlelight into one of the vineries and fed. Next morning before daylight they were taken to the apiary—at least, two lots were taken there and placed in front of the four hives to receive them. The third lot was placed in a remote corner of the garden, away from the other hives. The three hives meant to receive them were not together, but separate among the other hives. They were all allowed to fly about during the next day. About 5 o'clock P.M. the stocks to receive the bees were well fed with good syrup strongly minted, which was poured over their combs and then dusted with grated nutmeg. In about a hour after these hives were turned upside down, and the strange bees were cast into them like peas or corn from measure to measure, and over them a handful of chopped thyme was cast. These precautions were taken to prevent fighting and the loss of bees. I am happy to say that not a battle was fought, not a bee killed. Each of the hives got about 2 lbs. of bees, or ten thousand in number, which have made them strong stocks. The mint and thyme used helped much to effect a peaceful and happy union. Any strong-smelling substance would, I fancy, answer the same end if it over-mastered for the time being the

peculiarity of smell belonging to each swarm of bees. For the sake of experiment I will some day try assafoetida, which gives off a very strong and offensive smell.

The twenty swarms that I am feeding into stocks have not had syrup enough yet. Owing to the mild weather we have had of late bees have been out a great deal, and therefore have consumed much food. What a mistake the Swiss clergyman made in asserting that a large swarm of bees does not eat more food in winter than a small one! And what a strange thing it was that so many advanced English bee-keepers believed his statement!—A. PETTIGREW.

THE STEWARTON HIVE.

MR. PETTIGREW contributes an article on the Stewarton hive (see page 233), which I regret to say is most inaccurate both as regards its description and mode of management. It is really a rather unpleasant task to be required so frequently to demonstrate that "the captain on the paddlebox" is out of his reckoning, but the old craft must be steered straight at all hazards.

We are told "Two boxes octagonal in shape, 6 inches deep and 15 inches wide, with two honey boxes 4 inches deep, all with cross bars, make a Stewarton hive." It actually consists of at least three, not two, breeding boxes, 14, not 15, inches wide, with as many honey boxes as required, all without cross sticks. The slide space is not half an inch but three-eighths, which the merest tyro in bee-keeping knows is the unvarying width betwixt combs. I have wrought that hive successfully for the last twenty years, and have never before heard, much less have seen, the "crown board" upon it of which your correspondent dilates. The bar and slide is no innovation of the last ten years, but has been its sole crown board for seventy years. The slides are never shifted from the top of the upper breeding box to the honey boxes as your correspondent described, "with free access from both first and second floors to the attic," which is on no account allowed. Mr. Pettigrew is very far astray in stating "the queen can go into the super as often as she pleases without hindrance." She is strictly debarred therefrom by the central slides being kept always closed. This has been from the first, and still is, one of the best features of the hive, without which slides neither Mr. Pettigrew's straws nor any bar-frame hive I have yet seen, if we except the Lanarkshire frame hive, which has slides, can be wrought on the Stewarton principle. Stewarton colonies are not wintered in one box as Mr. Pettigrew supposes, but in two. The third box added in spring is not an empty box, but the combed box removed in autumn: hence his remarks as to drone comb are beside the mark, this "faulty feature" having no existence save in his own imagination. Neither is he happy in the depreciatory comparison as to the Stewarton form. "They resemble a lot of American cheese boxes or a bundle of riddle rims" he says, but must confess I have never yet seen either American cheese boxes or riddle rims of octagonal form; to my eye both articles would come in more suitable as ekes for big straw skeps. Mr. Pettigrew is, however, perfectly right that the Stewarton hive is not so generally well known as it ought, although the number of sets turned out annually is immense, several makers having almost constant employment in their manufacture, executing private orders; hence its sale is not freely advertised nor pushed.

How the Stewarton so far excels the big straw skep system I will endeavour to state on a future occasion.—A. RENFREWSHIRE BEE-KEEPER.

ARTIFICIAL COMB FOUNDATIONS.

YOUR new correspondent, Mr. Todd, has given us his experience as to the value of the recently introduced wax sheets artificially formed for comb foundations. He says he hopes to see his convictions of their value endorsed by myself and others after "experiment next spring." I am happy to be able already to endorse them by my past experience in the current year. Logic and fact are all in favour of this singularly useful and most ingenious discovery. Let these wax sheets only be fairly tried, and it is impossible for any sane person to gainsay their utility and economic use. From long experience I am convinced that Mr. Todd is far too liberal to his opponents (if he has any) in taking that "5 lbs. of honey go to make 1 lb. of wax." Presuming that the pound of sugar contains at least as much fatty or waxy matter as the pound of honey, I long ago came to the conclusion that it required somewhere about 20 lbs. of sugar at the very least to elaborate 1 lb. of wax. Anyhow, taking Mr. Todd's extremely "safe" calculation, he has fully proved his case on the ground of economy of material. I see that Mr. Pettigrew advises the disuse of all comb whether old or recently constructed. So recently as the middle of September he repeats his suggestion of the "desirability of having the combs in the stock boxes renewed every season," and adds "I am sure that this suggestion will in process of time be universally approved." I do not know how this may be, but I am equally sure that unless bee-keepers avail themselves of the help of these comb foundations, the waste of honey required every year to replace the old combs then discarded

will be found to be ruinously great. If, however, Mr. Pettigrew simultaneously adopts the new ideas, which have proved themselves logical facts of great value, there may be some foundation for his certainty as to the general yearly boiling down of old combs becoming the rule in bee-keeping.

Last autumn I bought a quantity of comb foundations (I think it was from Mr. Lee of Bagshot), about 2 inches deep. It was rather brown stuff, nor did I think much of it when I got it. However, one of my sons and I used it largely. A good deal of what I used fell down from the bars to which it had been affixed, owing to the weight of the swarm of bees suddenly clambering upon it. This I had to remove, but a considerable quantity of it is now part and parcel of the comb of the hive. It was freely used by the bees. One of my sons was more fortunate than myself, owing to his more dexterous method of applying the comb to the bars. Hardly any of his foundation comb fell down, but most of it was utilised in a very satisfactory manner by his bees. We are both so satisfied of the great advantage of this (to us) great discovery that we have just ordered a quantity more of Mr. Abbott's make, intending to make great use of it next year. Our hives for next summer are in course of preparation, and will all be supplied with these artificial helps. If next year's results are as promising as this year's experience leads us to hope they will be, we shall provide ourselves with a comb-making machine, and our condemned old combs will enable us to provide the wax material for the new artificial combs at a minimum of cost.

Mr. Todd remarks upon the "perfectly straight" combs which are insured by the use of these artificial comb foundations. This is a most important matter, by no means the least advantage of their use.—B. & W.

IMPROVED STEWARTON HIVES.

In reply to inquiries a description of the boxes which I employ may be useful, and enable your contributors to order what they require. My sets of Stewartons consist of three octagon stock boxes, each 7 inches deep and 14 inches in diameter, inside measure. They contain eight bars. The four central bars are framed, and with the bars on either side are $1\frac{1}{2}$ inch wide. The outside bars alone are $1\frac{1}{2}$ inch wide. The central frames are invaluable, enabling the apiarian to overhaul the hive whenever it is requisite with very little trouble, which with bars alone is not so easily accomplished. Supers are usually 4 inches deep and contain seven bars $1\frac{1}{2}$ inch wide.

The bees occupy either one or two stock boxes during the winter according to circumstances. Last winter out of three stocks one was allowed to retain two boxes, the others were reduced to single boxes.

The lower boxes when removed are carefully put away in a dry place well wrapped up to exclude moths and vermin, and are restored to their respective colonies as soon as the increasing warmth of spring enables the cluster of bees to expand and advantageously occupy a larger domicile.

When working a Stewarton hive all the slides are withdrawn between the stock boxes, so that the three form one hive with free communication between all the combs. As a rule only the outer slide on either side is withdrawn between the stock and the first super, and this is a most essential point in the management, as by this means chiefly is the queen excluded from the supers. If the central slides were drawn and a check occurred in the honey-gathering, the queen would almost certainly find her way into the supers and quickly commence filling any empty cells with eggs; the workers following suit would carry up pollen, and thus the purity of the super would be destroyed. As fresh supers are added at the top of the pile all the slides are withdrawn from the super beneath. You have thus a hive in two compartments, three stock boxes with free communication, where the bees rear brood and store all their pollen, and three or four more supers with equally free intercommunication, but cut off from the stock everywhere except where the withdrawal of the outer slides has opened a communication. Under these conditions I have invariably found the supers to contain nothing but pure virgin honeycomb.

Mr. Pettigrew thinks that the stocks ought to be broken up every year. My first Stewarton colony was established in 1874 (a single swarm hived in two stock-boxes). In 1875, a wretched season, I only obtained 27 lbs. super honey; 1876, 144 lbs. of super honey and 6 lbs. of slung honey; 1877, 63 lbs. of super honey; 1878, 57 lbs. of super and 7 lbs. of slung honey. The hive now contains a pure Italian queen bred last summer (1877), and is thoroughly prosperous, and the stock boxes are not clogged with a superabundance of pollen.

Next summer I shall probably remove the combs from the upper stock box after the conclusion of the honey season, and compel the bees to refill it with new combs, and if a second box is served in the same way the following season the hive will be quite equal to a new stock. It must be borne in mind when estimating the honey obtained from this single colony that we have no heather from which to obtain a second harvest, and this is by no means a specially favourable locality, as white clover

does not abound in the permanent pastures, and clover root is almost the only crop upon which we have to depend.—J. E. BRISCOE, *Albrighton, Wolverhampton.*

OUR LETTER BOX.

SOWING TARES (*M. Surrey*).—The sooner you get your winter tares in the better; no time must be lost, though not yet too late.

INDIGO BLUE BIRD (*Henry F. Foy*).—The blue bird you refer to is, no doubt, a species called the Indigo Blue Bird, several of which we have seen at exhibitions. The bird is about the size of a Sparrow, of robust appearance, with an entire blue plumage, and apparently as hardy as a Canary.

BERKSHIRE PIGS (*A.B.*).—It is not unusual to find such white marks as you describe on animals that are regarded as pure.

THE STEWARTON HIVE (*C. R. R.*).—This hive is made by Mr. James Allen, carpenter, Stewarton, Ayrshire, who charges from 20s. to 25s. for a set of two 6-inch boxes and two 4-inch supers, with a bundle of slides. No floorboard is sent with the boxes. Any country carpenter could easily make copies of this hive with one by his side.

FASTENING WAX SHEETS IN GROOVES (*E. S.*).—Embossed wax sheets are obtainable from Messrs. George Neighbour & Sons, 149, Regent Street, London. They are cut into strips, and after gently heating, what is intended for lower corners is rounded-off to prevent twisting and in imitation of the form in which the bee builds its comb naturally, is then set in the groove or saw cut found in the centre of each frame or bar, as the case may be, of a well-made Stewarton. Beeswax can be heated in a teacup, and, when liquid, with a teaspoon a little stream is run down either side of the sheet held perpendicular in the groove. When cool it is firm and sustains the weight of any number of bees.—A. RENFREWSHIRE BEE-KEEPER.

REMARKS.

25th.—Fair but rather misty morning, showery and dull the rest of the day; heavy rain at 8.5 P.M.
26th.—Misty morning; fine, bright, rather cool day afterwards; starlight evening.
27th.—Dull damp day, temperature warmer; dark night.
28th.—Fair but rather dull close day, much warmer than last few days.
29th.—Very misty in morning; afterwards fine and warm; quite a summer day.
30th.—Sharp shower 6.15 A.M., high wind at 7.45 A.M.; fine breezy day.
Oct. 1st.—Fine bright morning, cloudy in afternoon; damp night and dark.
Pleasant autumnal week, with a sharp squall on Monday morning.—G. J. SIMONS.

COVENT GARDEN MARKET.—OCTOBER 2.

Good samples of Grapes will now be in demand, but second-rate qualities will not improve in value till the Dutch are over. Pears are selling well, the supply generally being short. Some good samples of late Peaches are still to be had.

From observations taken near London during forty-three years, the average day temperature of the week is 60.6°; and its night temperature 41.4°.

PLEASURES OF HARDY FRUIT CULTURE.

It is but saying again what I have often said—"Increase your knowledge you increase your pleasure." But why do we often say the same things? why say them over and over again? Simply because we feel their truth. The belief in the mind, or the heart, prompts the tongue to speak; we must speak, we cannot help it. Life must be very dreary to one who has never exerted his mental powers, to one who has never cared to know many things. I grant that a man often succeeds in his calling who knows that, and that only. I knew a blacksmith so devoted to his trade that he went to the Great Exhibition of 1851 and made straight for the place where different kinds of horseshoes were to be seen, and having carefully examined them returned home contented, having only given a passing glance to other things. He was a very good blacksmith, but he would have been none the worse if he had learnt to appreciate other things besides horses' shoes. Tree, bird, flower, all contribute to our pleasure in proportion to our understanding them. I do not wish to be egotistical, and merely mention things that others may be benefited, but the plan I have followed for many years of always having something on hand which I am mastering in its details has added much to my happiness, and has often taken away that monotonousness which I have known people say is apt to be felt in the country. I would recommend people, in the country especially, to have on hand, as I generally have, two sources of interest at the same time—one for outdoors, another for indoors. Winter is coming, long evenings will soon be ours; take up, then, some subject which during those long evenings you determine to fathom, or some series of writers of the same period; this I have often done and with profit. Or pursue indoors the literary part of a subject, while outdoors in the summer you carry on the practical part. Books on gardening, or some branch of it, for indoor study. I saw it noticed lately that had Peter Cunningham lived in the country he would have been a Gilbert White, and produced a history like that of Selborne; or had Gilbert White lived in town he would have written a "Handbook of London."

But to come to my immediate subject—that of the pleasure of cultivating hardy fruits. We cannot all grow Orchids, we cannot all grow high-class hothouse plants, we cannot all grow (how I wish I could) hothouse Grapes, we cannot all manage—for as an eccentric old friend of mine used to say, "the Chancellor of the Exchequer forbids"—to gaze up at our own Muscats and Lady Downe's, or even Black Hamburgs; but we all with even a small garden can manage to grow hardy fruits.

As to the form in which to have the trees. I am speaking as an amateur, I would most decidedly say let them be pyramids, for these reasons—they are far prettier, they take up less room, and are so manageable; besides the fruit is not blown down. Winds must be high indeed to catch more than the mere top of a pyramid. Other forms may be used at times; thus an espalier turns a corner nicely,

and may be planted so as to screen from view a compost or manure heap, doing the duty of a Privet hedge with much more profit. A standard Pear tree comes in well to hide a high building or fill up a corner where nothing is wanted to grow. In such places a graceful, and even at times a majestic, Pear tree looks admirable. Also I would not object to a Scarlet Siberian Crab standard on a lawn, where also in some old-fashioned gardens may be seen one in one corner and another in another, a Quince and a Medlar; and I would say, Why not? Of course if you have an orchard on grass the standard is the form. Then if you have walls make use of every foot; Plums are best there, and Cherries too, besides the regular wall fruit. Half-standards suit well in some gardens, but if you go in for the pleasure of the thing, and some profit too, take to pyramids; you have variety of foliage and growth readily seen level with your eyes—some have large leaves, some smaller, some upright growths, some diffused. My eyes fall with pleasure upon this great variety. There standing before me is a Soldat Espere Pear which grows, pillar-like, straight up, and I seldom pass it without thinking of Mrs. Browning's line—

"The Cypress stood up like a church,"

and much like it is this Pear tree. Then next is a great pet of mine—Beurré Hardy, with its clear sea-green leaves, each leaf curved back, and this tree also grows upright, but diverse, though somewhat like its neighbour. Then there is big burly Beurré Diel, and large strong-growing Beurré d'Amanlis. Contrasting well with this stands graceful, delicate, small-leaved Winter Nelis, always on a shiver, Abele-like. That valuable winter Pear Bergamotte Espere has another kind of upright growth; while Summer Doyenné, Beurré Giffard, and Madame Treve spread wide with good dark foliage; while Seckle grows so round that it reminds me of a pegtop Beech.

Nor are Apple pyramids less different in ways of growing. Lord Suffield, delicate-shaped; Duchess of Oldenburgh, with almost red wood for its branches; Irish Peach, upright and regular in throwing out its arms; though none grows so accurately in this respect as Cox's Orange Pippin, which with the utmost regularity on each side of its upright stem sends out its miniature limbs, so that even a non-pomologist has paused and said, "How regularly that little tree grows!" Summer Golden Pippin, again, grows pleasantly to the eye; while New Hawthornden, with large, grand, dark leaves and wood, is most distinct and ornamental. Dumelow's Seedling, that best of winter cooking Apples, grows very regularly and rarely crosses its branches or incommodes itself with too much wood, but firm, long, lower branches to its top makes naturally a well-arranged and pleasing tree, one easily recognised by the grey specks on its bark. There are other trees that do not certainly please the eye nearly so much, and some seem over-slender for their fruit. Quite the contrary, however, to this are those fine strong-growing, sturdy, and upright, yet trusty, pyramidal Apple trees Cellini and Ecklinville. This individuality of fruit trees, seen to such advantage when they are grown as pyramids, is to my mind both interesting and pleasing, and gives distinctness to sorts, so much so that sometimes I can fancy I am looking at different kinds of

trees. But not alone are the trees interesting from variety of form and growth, but they please variously at different seasons. Those in winter from the form of the trees; in spring from early leaf and blossom; in summer and autumn from fruit and the changing hues of foliage.

No one can enjoy anything without bestowing care upon it, or as an idle man would say, "without a lot of trouble;" but this is a benefit according to my view, so that the thing enjoyed be not too exacting upon time and attention at awkward times. If a man makes hardy fruits his hobby he will not find it troublesome in the above respects. He may leave home for a while and not be heartbroken by finding his trees gone to rack and ruin, for a few days or weeks even will not cause this catastrophe. Neither is the chilly rheumatic man in terror when he sees the thermometer going down and about to touch freezing or go far below that. He need not mind; his pets are "hardy," no muffling up and off to "those Grapes." Sometimes when I have been coming home at night I have met the unfortunate owner (at such times he seemed unfortunate) going off lantern in hand, and his breath steaming in the frosty air before him, to "those houses," where he has been obliged to stay cold and shivering while I have been warm and cosy beneath the eiderdown. None of this miserable discomfort for me. My trees are—I repeat it—quite hardy. What care I for frost? Nay, I like it, for it will keep the blossom buds back. Spring comes, and, O ye readers of poetry! have ye never read of the beauties of Apple blossom? Talk of flowers, where are more lovely flowers? Rows of well-trained pyramid Apples are as charming to the eye as any bedding plants, and lines of pyramid Pear trees are like lines of miniature Horse Chestnuts. Then autumn comes, or in late summer time the fruit begins to show; and what more beautiful than an Irish Peach Apple when ripe, or, better, a pyramid well covered with these rich-coloured Apples? Then think of the form and colour of that beautifully striped Duchess of Oldenburgh. I might mention other Apples. But passing on to Pears: in them there is great variety of form to be found and difference of size, and in some richness of colouring. The Pear beats the Apple in the grace of form, the Apple the Pear in colouring. Is there no pleasure in gathering "the kindly fruits of the earth?" I think there is much. He who feels not grateful to the great Giver as he personally gathers the rich ripe fruit must have a hard heart indeed.

But the pleasure is not limited to one's own trees and fruit. The gardens and orchards of others have stores of pleasure for the man or woman who cultivates understandingly fruit trees. When I am driving through near villages and by gardens I notice what Apple is that, what sort of a Pear such a one is. This summer I paid a visit when at Stratford-on-Avon to the home of Shakspeare's wife. I own the orchard attached to that house of Ann Hathaway had its share of interest to me, especially one huge Pear tree which dated back to the last century perhaps, and which crowds of famous pilgrims had seen. But this taste brings pleasure in town as well as country. I am quite inclined to flatten my nose, schoolboy-like, on the window of the fruit shops, to see better by getting a closer view of the treasures piled up inside. I know no shops for beauty of fruit more remarkable than those at Ryde in the Isle of Wight, though I half fear some of the magnificently coloured fruits there seen are not grown in England. Bath too has splendid fruit in her (she is the queen of the west) shop windows.

A few words to finish this paper in the way of caution in order to avoid having your pleasures diminished in the cultivation of hardy fruits. First, beware of the jobbing gardener if you ever employ one. He will want to persuade you to let him cut off the lower branches of the pyramids, for this selfish reason, that he can better work under them. Sometimes a jobbing gardener will, without asking leave, take and cut off tier by tier the lower branches, thus utterly spoiling the trees. I saw recently the whole of the pyramids in a lady's garden ruined in this way: they looked like besoms stuck in the ground, so completely had all branches been removed except those growing upright at the top. Prevent such a catastrophe at all hazards; and remember these trees do not want working under or the ground digging, as the roots are and always ought to be close to the surface. I allow nothing but a hoe to be used, and hand-weeding is even better. Then don't over-prune. Cut out, of course, crossing branches—close-cut these; but as to endless pinching back and the rest, all ends in growing a thicket of useless wood. Remember trees must be kept thin for the light, air, and sun to get through them entirely and freely in summer as well as winter.

The bird trouble is sadly on the increase. All fruits this year have been attacked, and outdoor Grapes devoured. Bird protection has been romantically carried too far. Sense, not sentiment, should rule in this as in all other matters. Let me, however, not damp any ardent fruit-grower's spirits, for we have comparatively few troubles to face and few disappointments to meet. If you feel discouraged remember the beautiful fruit on the table cooked and uncooked: wives are pacified, children delighted, and papa's hobby voted capital for all.

Winter is coming on. Procure fruit catalogues from the leading fruit nurserymen; study them, you may learn much from them. Make yourself a present of Dr. Hogg's "Fruit Manual," and work at that of an evening: 'tis a bulky book and requires study, and will pay for close attention. Then when next year comes with its spring, summer, and autumn you will the better understand the pleasures in store for you in cultivating hardy fruits.—WILTSHIRE RECTOR.

FORCING VEGETABLES.

ASPARAGUS.

THE time is again at hand when vegetable forcing will call for attention. With good appliances it is an easy matter to have a supply of nearly every kind of vegetable throughout the winter that will submit to forcing; and even where there is no grand forcing house a fair quantity of produce may be secured by a little scheming and some trouble. Those who study to make the most of their conveniences always try to fill up every available corner with something or other, and by this means a large quantity of stuff may often be had with little expense.

In forcing it is very necessary to have one light and one dark place, and both heated in some way. Hot dung and hot water both serve good purposes. Asparagus may be forced with either; we do it with both with equal success. The hot-bed is that which could be most used as a rule, because there are few people who have a kitchen garden of any extent but who have something or other with which to make a hotbed, and there are many good gardeners with no hot-water-heated forcing house.

Where the hotbed will be resorted to during the coming winter no time should now be lost in preparing the bed if very early Asparagus is wanted. As the leaves are beginning to fall off the trees now all the best of them should be secured and placed in a heap. Grass cuttings should be secured in the same way; and just when the Asparagus growths are beginning to assume a withered appearance a quantity of stable litter and manure should be added to the leaves and grass, the whole being well mixed together and then made into a bed to suit any sized frame that it is desired to place on it. The bed should be made very firm, and the less of it exposed to wet the better. Indeed the margin of it outside the frame should be closely covered over with boards to throw off rain, as the heat of all hotbeds declines too fast when exposed to the cold winter rains. A one-light frame will hold as many roots as will supply several dishes, and where the demand is small no more than this should be put in at once. The bed may be made up about a week before the roots are lifted, and about 2 inches of soil should be spread over the surface inside the frame. When the roots are lifted they are simply packed close together on the top of this soil and covered over with about 2 inches more of light soil; they are then watered, the lights put on, and further than putting the lights down a little to let the steam escape on a fine day they require no further attention. The produce may be had ready for cutting in a month after the roots have been placed in the frame. We have cut in November twelve days after lifting the roots, but then they were in the bed of a Cucumber pit with hot-water pipes underneath them. In forcing the roots in this structure they are treated in all respects as in the hotbed, only they require more water, as the bottom soil is spread over the dry stones at the bottom of the bed. Some vegetables do not give so much produce when forced in autumn and winter as they do when the days are lengthening in spring; but the Asparagus is not one of them, as it yields just as much in November and December as in March and April. This was our experience of it last November and in previous years. Good roots from four to twelve years old force readily, but we do not prefer them either younger or much older than that.

We never make use of any roots after they have been forced, as we do not think it is profitable; and considering the ease with which Asparagus plants can be raised from seed, the best

way is to sow a quantity of seed every other year, and always have a nice batch of strong young roots coming forward.—
A KITCHEN GARDENER.

THE ROSE ELECTION.—No. 3.

I THANK "WYLD SAVAGE" for his kindly notice of the election. However galling to him, the Rose, it is satisfactory that to him, the man, the table and contents are of interest; if they are so to him, they are still more likely to be to those who are not so well up in the subject, and for whose special benefit I consider they are meant. Catherine Mermet is not, however, this year in the first twenty-four, seeing she is No. 28, and I, with "WYLD SAVAGE," wonder she is as low; but the election of last year, "delusive" as it was, placed her No. 20, so that I am rather at a loss to gather the source of his comfort. Can it be that he rejoices that that lovely Rose is eight pegs lower this year in an election that "is neither a delusion nor a snare to him?" As to Gloire de Dijon, I may say that I do not consider this glorious and kindly Rose has fair play for exhibition purposes. It loves to give us quantities of bloom at all seasons of the year; thus treated, is it likely to furnish exhibition blooms? Yet, even thus, a stray bloom shows us occasionally the metal it is made of. Shaded and prevented bearing more than half a dozen blooms (and it has in bygone days to my knowledge contributed to catch the judge's eye and bring the stand into the premier rank), I believe it would do so again; but grown as it usually is, No. 59 may probably represent its fair position.

By mistake the heading of the lists last week was that the Roses are in "order of merit." This was not asked for this year, though some of them are approximate. Though numbered, this has rather been to insure the correctness of the number of Roses named than to express their relative merits.—JOSEPH HINTON, *Warminster*.

VOTES IN ELECTION.

In the following returns the Roses are placed as the first best twelve, second best twelve, and next best twenty-four exhibition varieties.

Mr. J. GRAVELY, *Cowfold, Sussex*.

The above Reses are grown on very sandy soil.—J. B.

LARGE VERSUS SMALL BUNCHES OF GRAPES.

FROM the reports of the fruit shows this autumn it appears that "big" bunches of Grapes are decreasing. Neither at the Crystal Palace nor Edinburgh, two of the best fruit shows of the season where big bunches are encouraged, was there anything "sensational" exhibited; 16 lbs. being the heaviest at the Palace, and 8 lbs. 14 ozs. at Edinburgh. Certainly such bunches are out of the average production of Grapes, but we hardly recollect ever seeing these monster bunches well finished or in a condition that would win a prize for any other quality but size, and so far as table use goes such bunches are next to worthless. I would much prefer to see a perfectly finished and well-shaped Black Hamburg or Muscat of Alexandria bunch from 4 lbs. to 6 lbs. in weight, than a Syrian or other coarse sort weighing upwards of 20 lbs. Size of berry should

be of the first consideration. Fine, large, evenly-sized Hamburgs and Muscat berries always indicate high culture and merit, but a large bunch of a rough kind badly finished does not.

But while I am no advocate for large unserviceable bunches of Grapes, at the same time I think the other extreme should be guarded against. In the excellent report of the Show at the Crystal Palace which appeared in the Journal Sept. 26th, it is stated that the first prize (three bunches of Black Hamburgs) did not exceed "three-quarters of a pound each in weight." I am sure most gardeners will agree with me in thinking that this is going under the mark, and no matter how fine the few berries forming these bunches may have been, they were not examples to hold up for imitation in Grape culture. Anyone desiring to grow Grapes creditably should study to secure the finest Grapes with bunches averaging 3 lbs. A general crop of this kind well finished will be found far more useful than a few 16-lbs. bunches, and it is just to these medium well-finished bunches we would award prizes, but never to bunches under 1 lb. in weight.—A KITCHEN GARDENER.

THE WOOLHOPE CLUB.

THE annual Fungus foray of the Woolhope Club took place during the first week in October. It was attended by most of the leading mycologists—Messrs. Cooke, Smith, Renny, Phillips, Plowwright, Broome, Spencer Perceval, Lees, Vize, Howse, Bicknell, and others. The weather was remarkably fine, and with the exception of the afternoon of Friday no rain fell during the whole time. Although many of the common Agarics were absent, owing probably to the exceptionally early season, a larger number than usual of novelties were discovered, many of which have still to be studied and named.

The first excursion on Tuesday, October 1st, was arranged for the woods on the banks of the Wye below Symonds Yat station on the Monmouth line. Few Fungi were found; the mycologists were, however, much interested in the caves on the right bank of the Wye, in which bones of bear, hyæna, &c., have been discovered. Among the Fungi found may be mentioned *Tricholoma acerbus*, *Tricholoma ustalis*, *Pluteus chrysophæus*, *Flammula carbonaria*, *Leptonia incanus*, *Cortinarius anomalus*, *Lactarius uvidus* and *fuligineus*, *Marasmius erythropus*, and a *Clavaria*, which gave rise to an animated discussion between Messrs. Cooke and Plowwright, and was supposed by the latter to be *argillacea*.

The next day (Wednesday) was devoted to the classical ground of Dinmore. The time was short and the portion examined smaller than usual, but it yielded an unusual number of interesting species. Mr. Spencer Perceval found *Peziza saniosa*, a species with a violet juice, which has only been found once or twice before in this country, also *Strobilomyces strobilaceus*. In addition to this may be recorded *Hebeloma obscurus*, *Pholiota unicolor*, *Ecclia atropunctata*, *Mycena rosellus*, *Cortinarius callichrus*, *tabularis*, *afexipes*, and *sublanatus*; *Lactarius plumbens* and *pubescens*, *Panus torulosus*, *Thelephora Sowerbii*, and *Hypomyces rosellus*. In the evening a telegram was received from three Parisian friends—Messrs. Cornu, Roze, and Cintract, wishing success to the Woolhope meeting.

On Thursday, Sufton Court, the residence of Richard Hereford, Esq., was visited. This, like Dinmore, yielded many interesting species, among which may be mentioned *Mycena pellanthinus*, *Pholiota erebius* (Leveillanus), *Pluteus phlebophorus*, *Entoloma sinuatus* and *rhodopolis*, *Russula lepidia*, *Hygrophorus puniceus* and *pratensis*, *Polypones intybaceus*, *Clavaria pistillaris*, *Peziza leporina*, *succosa hemispherica*, and *Cortinarius armeniacus*. Mr. Plowwright dug up a rare tuber, a species of *Balsamia*.

In the evening the usual annual dinner took place, and afterwards Mr. Augustine Ley read an interesting paper on the Mosses of Herefordshire. Dr. Bull made an amusing speech, alluding to the various accounts of poisoning by Fungi. He read an extract from a paper describing how a man had been taken seriously ill after partaking of bread pudding, and thought if such a case had occurred it was not surprising that persons should be ill after eating improperly cooked and carelessly selected Fungi. He announced that Mr. Spencer Perceval and Mr. Howse had been elected honorary members of the Woolhope Club. Mr. Plowwright also alluded to the recent case of poisoning by Fungi in Norfolk, and stated that the species eaten had been selected in the dark and so covered up with pepper that their taste could not be recognised. *Hygrophorus pratensis* and *Clitocybe nebularis* were served at the dinner of the Club and both highly approved of, especially *C. nebularis*, which has the flavour of ketchup.

At the Fungus Exhibition in the large room of the Museum a considerable number of species were represented. The most remarkable were *Tricholoma frumentaceus*, brought by Mr. Renny, and a curious *Hypoholoma* with a connate stem, differing from *lachrymabundus* by its caespitose habit and dry gills. The Rev. M. J. Berkeley sent *Hygrophorus lacmus*, *Hygrophorus turundus*, and *Hygrophorus Wynnei*, the last a new species. After the dinner

a soirée was held in the house of Mr. Cam. Dr. Cooke read a paper on *Corticium*, a marvel of patient research in that difficult genus.

"In tenui labor, sed tenuis non gloria."

After this there was an interesting controversy between Dr. Cooke and Mr. Phillips on *Peziza crucifera*, established as a new species by the latter. This *Peziza* is very near to if not identical with *P. virginea*, but has cruciform crystals of oxalic acid on the surface of the hymenium. Dr. Cooke thought that the presence of an inorganic body in a plant, unless it served some special purpose, was not a sufficient reason to establish that plant as a new species. Sun and rain would soon destroy these crystals and

reduce the *Peziza* to the ordinary state of *P. virginea*. Mr. Plowright supported the views of Mr. Phillips.

Mr. Vize exhibited *Aecidium ornamentale*, a fine exotic species many times larger than any we are acquainted with in this country.

On Friday the usual excursion was made to the charming Downton Woods, near Ludlow, always prolific in rare Agarics, and rendered doubly (someone said fortyfold) agreeable by the hospitality of the Messrs. Fortey. A large number of interesting Fungi were gathered, and some were new species yet to be identified. The great feature of the day was the presence of an unusual number of *Strobilomyces strobilaceus*. It usually occurs, if found

Fig. 42.—WOOLHOPE MENU.

at all, very sparingly; but on this occasion Mr. A. S. Bicknell discovered nearly fifty individuals growing together, but he prudently did not make known the locality to the rest of the party. Besides this may be mentioned *Tricholoma inamœnum* and *cuneifolius*, *Clitocybe odoratus*, *Entoloma clypeatus*, *Pholiota heteroclita*, *Leptoma chalybeus*, *Cortinarius torvus*, *elatior*, *cinnabarinus*, and *bolaris*, *Hygrophorus lacmus* and *erubescens*, *Clavaria botrytis* and *amethystina*, *Russula lepida*, *lutea*, and *cyanoxantha*, *Peziza onotica*, and *Hypomyces rosellus*. Mr. Fortey found the very rare *Sphaeria Albertini*. In the afternoon the party returned through Oakley Park, the seat of the Clive family, now represented by Lord Windsor. The old Oaks were much admired. They are supposed to be over two thousand years old, as they are mentioned as old trees in Domesday Book.

Pholiota terrigenus was found in the grounds, and fine specimens of *Fistulina hepatica* on the Oaks. The party then returned to Hereford, much pleased with the result of their labours. Several of the party proposed attending the Edinburgh meeting in the following week.

"O dulces comitum valete cœtus!
Longe quos simul a domo profectos,
Diversos variæ viæ reportant."

—T. HOWSE, F.L.S.

WOOLHOPE MENU.

THROUGH the kindness of Mr. W. G. Smith, the talented botanical artist and fungologist, we are enabled to present our readers with a copy of the menu which that gentleman designed

for the dinners of the Woolhope Naturalists' Field Club. It is not easy to decide whether to admire it more for the artistic talent displayed in the design or for the perfect wit and humour which the design illustrates. The menu first appeared in the pages of a contemporary with the accompanying description—"Beginning at the top, the pleasant faces seen in the 'edible' Fungi, and the dolorous mementos manifest in the 'poisonous' ones, explain themselves. The former are suitable for frying, and Fries is the greatest living authority on Fungi; the latter cause unpleasant symptoms and pain us—"Panus" is a genus of Fungi; the pill box, pill and medicine bottle, are represented by the genus of Fungi named 'Pilobolus.' Mr. Berkeley in the top centre is being attacked by a starry Puff-ball (a species of vegetable octopus), and his exclamation of affright naturally takes the form of another genus of Fungi named 'Odontia.' It will be observed that Mr. Berkeley, who is applying 'salus' to the nose of the monster (a material 'no Fungus can withstand') has let fall his 'Outlines of Fun-gology.' The bottle of 'Currey' on the left immortalises Mr. Fredk. Currey, the famous fungologist. 'Kneiffia' underneath is a genus of Fungi, and 'Forkia' is a genus shortly to be established. The cuneiform inscription indicates the character of the fungoid octopus and the Colorado beetle at Hereford. The porcine quadruped on the left points to Dr. Robert Hogg, who has published a book on Fungi, and the inscription 'Non Sow.' indicates that he is not to be confounded with Sowerby. The umbrella handle and great knife on the left always appear at the Hereford meetings: they belong to Mr. Plowwright, the famous surgeon and fungologist of King's Lynn. The wine bottle bears the name of the renowned wine merchants of Rood Lane, who supply so many Fungus eaters with their (as pronounced after dinner) 'Sphæria champign.' Sphæria is an immense genus of Fungi, and 'champign' is Champignon with its tail off. On the right we have Dr. Bull, the physician of Hereford, supporting 'Cornu' (Latin for Dr. Bull's Horn of Plenty). M. Max Cornu of Paris is one of the highest living authorities on Fungi, and was a guest at Hereford. The chains and ropes ornamenting the bovine nose indicate the power and irrepressible energy of Dr. Bull. Leveille is the name of a great Fungus author, and refers at the same time to the 'veal' which at an early period clothes the bones of all oxen. 'Magnus' refers to Dr. Magnus of Berlin, the fungologist. The greatness of this author's name has expelled the cork from the bottle. 'Bad-ham' on the dried pig's leg refers to Dr. Badham, who wrote the 'Esculent Funguses of England'; whilst the mole hanging head downwards indicates the miserable condition of Mr. Lee's 'molar theory,' which referred the formation of fairy rings to the underground gyrations of the mole. 'Hygrophorus' (the Water Bearer) is the name of a large genus of watery Fungi; and the 'Myxomycetes' are a large group of Fungi now attracting peculiar attention. Phallus is a genus of Fungi, which does service here in indicating that there is 'no fallacy' as to the quality of the wine consumed. Some Fungi bear spiral corkscrew-like springs for use in dispersing the spores; the springs are named 'elaters,' therefore the corkscrew figured is in more senses than one an 'elator.' The bottle of cider on the left and Agaricus cidaris are synonymous, and 'Du-Port' on the right is the name of an excellent fungoid clergyman from Norfolk who attended the Hereford meeting. Arriving now at the bottom we have Tode, a writer on Mushrooms, together with a figure of Boletus edulis beheaded. Hussey, Broome, Cooke, and Curtis are all renowned fungologists. Hussey and Cooke are in conflict: the latter has just thrown a rolling-pin (Clavaria—a genus of Fungi) at the latter, and is now in the act of discharging a basin of batter (Batarrea, another genus of Fungi) at her opponent. The cook's name is Psalliota, a sub-genus of Fungi; the hussy's name Polyporus, a large genus of the same class of plants. 'C. E. B., M.A.,' on the hussy's weapon, point to the name and degree of Mr. Broome the fungologist. 'Sparassis' is an important genus of Fungi, which is here giving a hint to the combatants as to how to proceed when their artificial weapons are no longer available. 'Crucibulum' is the name of a large genus of Fungi, and means a saucepan: the 'Batch' inside is the name of a great Fungus author. 'Flammula,' a little flame, is a sub-genus of Fungi; and 'Fries Epi-crisis' (the fat-in-the-fire) is the name of the best text-book of Fungi in existence."

year bloomed at Sudbourne Hall, Wickham Market, Suffolk, the seat of Sir Richard Wallace. The stems are about 24 feet high, with branches very short and thickly set together at the top of the stem, farther apart lower down, and not opposite one another; the flower branches do not grow near the leaves, but are quite 3 feet above them. There were thirty-two branches, and taking each truss to average eighty blossoms, there were about 2700 flowers on one plant. The flower buds look a pale greenish white tipped with bright yellow. The flower lasts from three to four days; the scent is most disagreeable. An immense quantity of honey drops from the flower. The thickness of each leaf next the stem is from 6 to 8 inches; the width of leaf at the base is over a foot; length about 6 feet. The leaves are dark green, with stripes of yellow round the edge. These plants are said to have been in the conservatory nearly eighty years. As soon as the flowers expand the leaves begin to droop, and the plants gradually die away. The dry stem of a plant that flowered about eight years since is preserved in two pieces in the conservatory; and although nearly 27 feet long, can be easily carried about by a lady or child, being as light as a piece of cork. A fine plant of this Aloe is now flowering on the terrace at Hampton Court, from which hundreds of bees are constantly gathering honey during fine days.

FORTY GOOD ROSES, NOT FORTY THIEVES.

THERE are some Roses which I will not name that are appreciated by exhibitors that would ruin persons not versed in Rose-growing, and no doubt exhibitors find it difficult to keep them going. I propose to give a list of forty Roses which are good for the public—the careless public. If they cannot get on with those I name the sooner they take to cultivating Ragged Jack the better.

Hybrid Perpetuals.—Abel Grand, Anna Alexieff, Baron Adolphe de Rothschild, Baronne Prevost, Caroline de Sansal, Charles Lefebvre, Maréchal Vaillant, Edouard Morren, Duchesse de Caylus, Glory of Waltham, Gloire de Vitry, John Hopper, La Ville de St. Denis, Lord Clyde, Madame C. Crapelet, Madame de Cambacères, Madame Charles Wood, Madame C. Joigneaux, Baronne de Rothschild, Madame Victor Verdier, Mlle. Marie Rady, Marguerite de St. Amand, Marquise de Castellane, Maxime de la Rocheterie, Maurice Bernardin, Paul Neyron, Pierre Notting, Pierre Seletzky, Princess Mary of Cambridge, Queen of Waltham, Star of Waltham, Souvenir de Dr. Jamin, Vicomtesse de Vezin, William Griffiths, and Souvenir de la Reine d'Angleterre. The above are Hybrid Perpetuals.

Bourbons.—Baronne de Maynard and Souvenir de la Malmaison.

Yellow Roses.—Three of the best and most continuous bloomers in the Rose kingdom are Triomphe de Rennes, Céline Forestier, and Gloire de Dijon.

All of the above Roses have done well with me this season, besides some others.

I hope such beautiful Roses as Dr. Jamin, Baron Chaurand, Empereur de Maroc, Baronne de Maynard, Louis Van Houtte, and Louis XIV. will not be given up because they are small. The two first and two last are the most beautiful of the high-coloured Roses, whilst Pierre Notting is the more desirable. Maxime de la Rocheterie is a fine, full, bomb-shaped, dark Rose and a good grower. The high-coloured Roses as a class are not good growers. Pierre Notting, Maxime de la Rocheterie, Dr. Jamin, and Empereur de Maroc are the best growers here in the dark line and they live on. To some of the Roses named in Mr. Hinton's schedule I may address the well-known words, "Are, César! Morituri te salutant."

The Roses here are blooming respectably now, and I may say that for twenty-seven years I have not seen the Roses so fine. I dress them in the winter with liquid manure from a twenty-six cow dairy and fattening pigs.

The two finest corymb Roses are Triomphe de Rennes and Baronne de Maynard. Sir J. Paxton is also a splendid corymb Rose. They bloom continuously from the beginning to the end of the season.—W. F. RADCLIFFE.

FORCING TULIPS.

As the time is at hand when bulbs are procured for the ensuing season I think a few remarks on forced Tulips will not be inopportune. Duc Van Thol with its various colours is the best kind for forcing. It is supposed by many that the

AGAVE AMERICANA (The American Aloe).—Two of these plants, says "R. M. S." in "Midland Naturalist" have this

Tulips which are seen in Covent Garden during the dullest months of the year are grown in the pots they are exhibited for sale in; but this is not so. They are managed thus: The bulbs are placed thickly together in pans or boxes, and placed under cocoa-nut fibre until they are well rooted, when they are placed in heat and close to the glass. A temperature of about 55° to 60° is quite hot enough; if higher they become drawn. After the flowers have well shown their colours the plants are potted into 48-size pots. Three reds and two whites are generally how they are placed, or the plants can be introduced after removal into baskets or vases. Keep them close for a day or so and inure them to a cooler atmosphere, when they will be fit for use either for the conservatory or dinner-table decoration.—A SOUTHERN GROWER.

DUPLICATE ROSES.

ABOUT election time last year a discussion was originated by "WYLD SAVAGE" and Mr. Hinton, and taken part in by many, upon the similarity existing between the following "sets" of Roses:—Mons. Boncenne and Baron de Bonstetten, Eugénie Verdier and Marie Finger, Ferdinand de Lesseps, Maurice Bernardin and Exposition de Brie, Louis Peyronny and Lælia, and others. Much was said about the needlessness of having more than one of each "set" in a small collection, but I do not think anyone said which was the best one of the "set" to have. One gentleman said which was the brightest and which the darkest, another spoke of the difference in the wood, and a third referred to the shape.

With the exception of a small Briar plant of Baron de Bonstetten, which has never bloomed, I do not possess either at present, and in common with many other small growers I can neither spare the money to buy nor the room to grow a lot of all these sorts; but I want to know which is the best "all-rounder," combining hardihood, freedom of bloom, and shape of each family. So if some of the knowing ones will tell us we shall be greatly obliged. It seems to me that La France and Capitaine Christy come under the category of those Roses that small growers need not have both of, for if we except a slight difference in shape they are very much alike. Ferdinand de Lesseps as exhibited at the Alexandra and Crystal Palaces this year appears to be rather a ragged, loose character. Is it so? It is quite possible that I am wrong on both these points. If so, I hope someone will tell me so, as I am not a "Hercules" or a "Savage" but only—A LOVER OF ROSE SHOWS.

NOTES AND GLEANINGS.

THE WEATHER in the south has during the first week in October been of the most brilliant character—quite, as many have remarked, a second summer. The sunny days have been specially acceptable to gardeners who have had to wage for many weeks an incessant war against weeds, and even then the weeds too often conquered. Gardens, which it has been almost impossible to keep clean during the summer, are now assuming a neat appearance, so far at least as falling leaves permit, and are yet bright with autumn flowers, frosts as yet having done little or no damage to tender plants. The dry sunny period is also very opportune in ripening the wood of fruit trees, which, owing to the absence of fruit and prevalence of wet, have generally made exuberant growth this year.

—WE remind our readers that at the meeting of the Fruit Committee of the Royal Horticultural Society on Tuesday next, the competition for the prizes offered by the Messrs. Pearson for their NEW GRAPES, Mrs. Pearson and Golden Queen, will take place. The latter Grape we have seen very fine in certain places this season. We are also informed that many of the growers have signified their intention of exhibiting collections of fruit and also Potatoes, so that a very interesting meeting may be anticipated.

—IT is very seldom, writes "A SOUTHERN GROWER," that well-grown PELARGONIUMS are seen, especially in small pots, and the reason is generally that the plants are kept too close and moist at the roots during the winter. If growth is encouraged during the dull short days the plants are sure to be drawn, the wood does not ripen, and the result is very little bloom. Abundance of air and light, and only enough water to keep the plants from suffering, is the plan to adopt until February. At that time they must be well watered and never afterwards be allowed to become dry, or they will lose a great

part of their foliage. Another mistake is to give liquid manure before the plants show buds, which causes them to make rank growth, which cannot thoroughly ripen. If they are treated as above directed the wood that is made in winter will be stout and short-jointed, and the plants will flower profusely.

—ACCORDING to custom, notifications are issued that the SURPLUS BEDDING PLANTS in the London parks, Kew Gardens, and Hampton Court will shortly be distributed to the industrial classes who apply for them through the clergy, school managers, and other representative bodies, who can obtain information as to the time of distribution by applying to the Superintendents of the parks. Some of the applications for plants we are informed are very amusing, amounting to large orders of Roses, shrubs, &c., the applicants appearing to be ignorant that only such bedding plants as Geraniums are distributed.

—THE monthly meeting of the SCOTTISH HORTICULTURAL ASSOCIATION was held on the 1st inst. at 5, St. Andrew's Square, Edinburgh. The Vice-President, Mr. Hugh Fraser, occupied the chair. Mr. Charles Taylor read a paper on the Theory of Fern Spores, illustrating his remarks by diagrams. He described the views generally held on this subject, and, after tracing the development of spores, concluded by urging the members to give more attention to this question than they had hitherto done, as it opened up a wide field for fresh and important inquiry. Mr. Andrew Kerr continued the subject by another paper, in which he gave his experience in the treatment and culture of Ferns in a very elaborate manner. In the discussion which followed it was stated that *Adiantum gracilimum* was a sport from *Adiantum cuneatum*. This was borne out by the personal observation of several of the members present. The following plants and flowers were exhibited by Mr. L. Dow:—*Aralia spinosa*, two varieties of *Hibiscus*, *Spiræa Foxei*, and *Myrtus communis*, all in a profusion of flower growing out of doors; by Messrs. Dickson & Co. a stand of *Violas* and *Cyclamen europæum album*; by Mr. A. McKinnon four varieties of the autumn *Crocus*; by Messrs. Downie and Laird a splendid stand of seedling *Phloxes* of their own raising, and *Rhododendrons* Duchess of Edinburgh and Princess Royal; by Mr. R. Morrison a Fern case admirably adapted for raising Ferns from spores.

—THE business of the old-established house of Fergus Farrell & Sons, seedsmen, Dublin, has been purchased by Messrs. WALTER TAIT & Co. of that city, who will carry it on in conjunction with their own establishment.

—MR. HARDING informs us that he has lately seen not far from Peterborough a plant of *FUCHSIA RICCARTONI* trained against a stone wall facing the north-east. The plant is 10 feet in height, and from its appearance it looked as if it had been there during many years. It appeared to have had a tying-in or nailing once a year and the summer growths left to grow out from the wall, and the sprays of flowers were very beautiful. With its free-branching habit and profusion of flowers it is very useful when cut flowers are wanted in quantity, and it is in full bloom from July to November. Plenty of rain seems to benefit this plant.

—A NOTICEABLE and attractive feature in the Fulham Nurseries just now is a batch of *SKIMMIA JAPONICA*. The plants range from 1 to 2 feet in height, and amongst them may be found pyramids 2 feet in diameter at the base: yet the plants vary in shape, some of the tallest have a flat face to them, others of the dwarfest type are flat. The whole of the plants are densely covered with scarlet berries brighter than they are often seen. These plants were lifted from the open ground last season, placed in a pit until after the flowering season, when they were again placed outside: hence the result, which is highly creditable to Mr. Fancourt, the manager.

—SOME of the late kinds of POTATOES taken up in September in the neighbourhood of Peterborough have turned out very much diseased; Scotch Regents, Hundredfold Flukes, King of Potatoes, Paterson's Victoria, nearly one-half; while of Red-skin Flourball and Red Regent not 2 per cent. were diseased. Myatt's Prolific, Ashtop Kidney, and American Early Rose amongst early kinds turned out very prolific; the former two kinds being quite free from the murrain, and the latter kind about one bushel out of sixty at digging time (first week in August) were found bad, but in sorting over a fortnight later about 10 per cent. were taken away diseased.

—WE have pleasure in confirming the announcement

made in the *Standard* of October 1st, that a gold and also a silver medal have been awarded to MESSRS. SUTTON & SONS, the Queen's seedsmen, Reading, for their extensive museum of seeds, Grasses, models, &c., at the Paris International Exhibition. Visitors will doubtless remember this fine display of horticultural and agricultural produce in the gallery of the English agricultural annexe, and it is very gratifying to find that in this department the great firm sustained their world-wide reputation.

RABY CASTLE.—No. 1.

RABY CASTLE, the seat of the Duke of Cleveland, is situated in the southern division of the county of Durham—a county rich in coal, and rich also in historic associations. There is, perhaps, no place more replete with all that is interesting to the visitor than the proud baronial residence of Raby. Whether the visitor be a poet, novelist, or artist, and imbued with

the spirit of study, he will find much to awaken his interest there.

Raby Castle stands near the ancient village of Staindrop, and Barnard Castle is also adjacent. Staindrop was a village of great repute in the time of Canute, whilst a college was erected there in 1378 by a licence granted by Bishop Hatfield to Ralph Neville, Earl of Westmoreland. Here in the church are buried many members of this ancient family. Staindrop is only one mile from Raby,

"Staindrop, who from her sylvan bowers
Salutes proud Raby's battled towers."

On approaching from Staindrop the scenery is very fine. There are four approaches to the Castle through the park, in which is some magnificent timber.

The Castle itself is a pile of stately towers, and conveys to the visitor a most impressive idea of a great baronial palace in the feudal ages. It is surrounded with a parapet and embasured wall, together with a deep fosse, in which there used to

Fig. 43.—RABY CASTLE—NORTH-EAST SIDE.

be a drawbridge to the then only entrance to the Castle. Here, some historians state, stood Canute's mansion, which he yielded to the church of Durham. The beauty of the present building is due to John de Neville, who in 1379 obtained a licence to "make a castle of his manor of Raby, and to embattle and crenulate its towers." Into the inner area of the Castle there are two entrances, the most ancient one being from the west, which consists of a double way, square towers, and a portcullis let down before each gate in time of danger. The style of architecture is pure Gothic, which is still retained in all its pristine character. All repairs that are executed are done in unison with that style. Mr. Grosse says this Castle, "with its nearly circular terraces enclosed within a military wall, measures nearly two acres, and the immense demesne to exceed thirty miles in length." The south front is very beautiful, but the east front, with its lofty and embattled towers, presents a most imposing appearance.

The interior of the Castle is equally imposing. The entrance hall is very large, and is constructed so that carriages can drive in—we believe the only castle in England that contains such an arrangement. A flight of steps from the hall conducts to the presence chamber. The great baronial hall is very antique and of great extent, being 120 feet long by 36 broad. "Here

assembled in the time of the Nevilles seven hundred knights who held of that family." Many of the rooms present modern improvement, due regard having been paid to sanitary and acoustic properties. The Castle abounds in pictures—paintings by most renowned ancient and modern masters. Many of them are portraits, representing personages of this ancient family. Statuary, articles of vertu, old china, &c., also abound there. The ancient writer Leland in speaking of this Castle says, "Raby is the largest castel of loggicers in all the north country; ther belong three parkes to Raby, whereof two be plenished with dere."

The origin of the owners of Raby is of great antiquity, and many of the members of the family have attained historic celebrity, some of them having been famous as warriors, whilst others have ranked high as eminent politicians. Ralph Neville, born at Raby, was Lord Chancellor to King Richard III. This family assumed the name of Neville through marriage with the Nevilles of Brancepeth, whose large estates they obtained, the head of the family being raised to the Earl of Westmoreland. The title, according to Dugdale, became extinct with the sixth earl, who died in exile. The estates became confiscated, and were placed in the hands of some citizens of London in trust to be sold, and were pur-

chased by Sir Henry Vane, who was an ambassador to several foreign states, and who entertained King Charles I. twice at Raby, in 1633 and 1639. Raby was also besieged during 1645 and again in 1648, and strange to say the only account of this latter event is in the parish register at Staindrop church. In 1699 this family received the title of Baron Barnard, another member received the title of Earl of Darlington in 1754, whilst in the same century the family were raised to the dukedom, and the present distinguished nobleman is the fifth who has shared the title.

There was at one time a village called Raby, but this was removed to make improvements around the Castle. The situation of the Castle is very lovely; situated on rising ground it commands a rich view, on the east and west bounded by distant hills, and on the south is a plain, whilst nearer the horizon are beautiful plantations raised by the late Lord Darlington. Of the four approaches to the Castle one is for domestics, another leading to the Darlington road, a

third from Staindrop bridge, and a fourth from Durham. The ornamental grounds about the Castle are disposed with great taste, the lawns and water scenes being specially fine. This park also contains an extensive collection of red and fallow deer, which lend an additional charm to the entire surroundings.

We have lingered awhile on the historical connections of Raby. We will now commence to describe the gardens, which are placed under the care of the indefatigable superintendent Mr. Westcott. There are few gardeners who have not heard of these gardens. About half a century ago many pages were written on the Raby Vines which were grown in carrion borders, the entire failure of this system being now thoroughly understood. The glass is of great extent, every department is carried on effectively and on the most approved principles. On entering the conservatory, which is a large structure, 81 by 24 feet, we found the walls very finely covered with climbers, conspicuous amongst which were *Fuchsia Dominiana* and

Fig. 44.—RABY CASTLE—EAST FRONT.

Plumbago capensis with its charming lavender-coloured flowers. There were also the usual concomitant of plants required for floral decoration, and remarkably fine Ferns. We must not omit to mention the magnificent Cockscombs which had received the first prize at Bishop Auckland. They were of a rich crimson colour, and measured 21 inches over and 11 across. This is a strain of Mr. Westcott's own. Near the conservatory was a very good example of subtropical bedding, including Cannas, Wigandias, Castor-Oil Plants, and Zeas, all of which were very good. Passing on we come to a space of ground which is enclosed by a magnificent Yew hedge, planted at least a century ago, and is about 12 feet broad at the base. Here are two magnificent Walnut trees and a fine example of bedding-out, the rich dark shade of the Yew showing to advantage the gay colours of the flowers. The most fastidious could not but find much here to admire in the happy arrangement of the colours in this enclosure. Clematis Jackmani is used with a happy effect. Carpet bedding is also done, in which *Alternantheras* were beautifully coloured, and for the north were quite surprising to us. Mr. Westcott uses for carpeting a variety of *Gnaphalium tomentosum*, which is a fine, feathery, silvery-leaved plant worthy of extensive culture for such work. It is not easily propagated in the autumn, the best method is to take up old plants. Adjoining here is the Rose garden, in which dwarf Roses were pegged down with standards above

them. A fine rose Carnation in beds named the Raby Carnation was very effective. The glass structures and kitchen gardens will be noticed in a future issue.—B. COWAN, *Acnell Park*.

THE ROSE ELECTION.

I WOULD most heartily second the vote of thanks which our good friend "WYLD SAVAGE" offers to Mr. Hinton for the trouble that he has taken in producing so valuable a guide to Rose-growers as the list of the seventy-two best Roses given in the Journal for September 26th. These thanks are all the more due that this trouble has been taken in the midst of what I ever consider the most laborious and trying of all lives, the practice of a doctor in a country town; trouble, too, which involves, not the going through one's own garden quietly smoking the pipe of contentment, but the consumption of the midnight oil after, it may be, a hard day's work, the tabulating of a number of returns, the deciphering of bad writing, and the unravelling of many a yarn. "Mr. Hinton has deserved well of the republic" of Rose-growers.

He hardly asked me to give a return; but as I do not aspire to the honour of being an exhibitor, to which class I understood from him it was to be confined, I asked to be excused, and so my thanks are all the more due to him. "WYLD SAVAGE" has pathetically lamented the position which he occupies as

No. 71, but it is to me not a little remarkable that English-raised Roses make so poor a figure in the list. The last few years have seen a considerable number of these sent out by Messrs. Paul & Son, Turner, Wm. Paul & Son, Cranston, and others, yet of those sent out in the last ten years not one occupies a position in the first twelve. In the first twenty-four only one (Reynolds Hole), for Duke of Edinburgh came out in 1868. As far down as 48 there are only four—the two named, Star of Waltham, and Sir G. Wolseley; and in the whole seventy-two only nine, adding to those named Annie Laxton, Royal Standard, Miss Hassard, Duke of Connaught, and Rev. J. B. M. Camm, and these last having only nine, eight, and seven votes out of forty-one voters. Surely the judgment of Floral Committees and of the great Rose shows cannot be so defective. It is one of those things “no fellow can understand.”

On what ground does Mr. Hinton ascribe the honour of raising Lord Macaulay to Mr. Ward? I think there is an error here. Is he right, too, in saying that poor Mareast was the raiser of Souvenir d'Elise? I always thought he only raised one Rose, which I grieve to see nowhere in the list—dear wee Comtesse de Chabrillant. Times are altered since wee women were considered as the Venus de Medici, the type of feminine grace. We must now have Comtesses and Made-moiselles with the size of portly matrons of the aldermanic type fed on turtle and venison. “Times alter, &c.,” but at any rate love for the Rose seems undying, and may the Rose election be helpful to many of the real lovers of the flower.—D., Deal.

In comparing this year's election with last I note that many Roses have considerably changed their position for better or for worse. The following are increasing in favour:—Duchesse de Vallombrosa has advanced the astonishing number of 36 places; Star of Waltham, 17; Capitaine Christy, 12; Comtesse de Serenye, E. Y. Teas, and Pierre Notting each 11; Beauty of Waltham, 10; Duc de Rohan, 9; Duc de Wellington and Reynolds Hole, 7; Fisher Holmes and Mdle. T. Levett, 6; and Jules Margottin, which was not included in last year's seventy-two, now stands 47. The following Roses are losing favour:—Edouard Morren has fallen 16 places, Mdle. M. Cointet and Victor Verdier 13, Prince Camille de Rohan 11, Madame Charles Wood 10, Dupuy Jamain and Emily Hausburg 9, and Princess Mary of Cambridge, which was placed 51 last year, this year is not placed at all. These remarks apply only to the general election of the best forty-eight.—CURATE OF HOWDEN.

THE INTERNATIONAL FRUIT SHOW AT THE PARIS EXHIBITION.

THE great feature of this Show was the competition between the numerous local societies of France, Austria, Denmark, Brussels, the Netherlands, &c. The staging for this portion of the Show ran north and south the whole extent of the Exhibition, which must have been half a mile in length. Among the many societies competing were those of Villemomble (100 plates), Nancy (1200), Meaux (148), Lille (400), Fontenay-le-Comte, Vendée (250), Orleans and Loiret (400), Lisieux (Normandy), all showing very large collections. But the Brussels Society exceeded all in quantity, as there were two thousand plates shown. Besides these M. Eugene Targent exhibited 120 plates, Madame Claudon 100, and M. F. Jamin about the same quantity. These numerous collections consisted chiefly of Apples and Pears, although some few societies exhibited Grapes and Peaches. But the chief Peaches were arranged in another portion of the Show.

After the fine exhibition of Grapes at the Crystal Palace I was not particularly impressed with any that were shown at Paris. Most of the Apples and Pears were good, the Pears in many cases being exceptionally fine. The Apples were not superior to many I have seen shown at different times in England for colour and general appearance. But there was a superiority in size of many of the kitchen Apples, notably Reinette du Canada, Belle Dubois (Gloria Mundi), Calville Blanche, Emperor Alexander, and a few others. Many of our best kinds of dessert Apples were but sparsely shown, at the same time there were many handsome in appearance, but the quality of which it was of course impossible to ascertain. Besides the Apples mentioned above I saw the following very good:—Royale d'Angleterre, Belle Joséphine, Reinette de Caux, Reine du Reinettes, Reinette Grise du Canada, Bedfordshire Foundling (I was astonished to find this Apple so universally grown), Calville St. Sauveur, Calville Rouge, and others too numerous to mention. I measured two Alexanders of M. Targent, each 15½ inches in circumference. The chief Pears shown for appearance were Duchesse d'Angoulême (everywhere), Beurré Diel, Beurré Clairgeau, Colmar d'Aremberg, General Todt-

ben, Triomphe de Jodoigne, Délices d'Hardenpont, Joséphine de Malines, and Belle Angevine. I would not dispute the dictum of Dr. Hogg as to this Pear being synonymous with Uvedale's St. Germain, but as shown it was browner in appearance than those grown in England. The Grosse Calebasse was very large indeed. The colour of the Austrian Apples was very striking, they outdid for artificiality of appearance a wonderful collection of modelled Apples, Plums, and Pears exhibited by M. Garnier Valletti François of Turin.

Another feature of this portion of the Show might be followed with great advantage by many other societies. The Horticultural Society of Clermont had portioned off a few sorts from their collection, and put up a notice saying that these sorts were not worth growing. I found one sort that I had noted among them, and immediately erased it from my note book. At every show people are to be found jotting down the names of different productions without any knowledge of the qualities of the exhibit. If we could ascertain the bad as well as the good sorts by visiting shows I think it would be of equal benefit.

The other portion of the Show was held in two long buildings between the Exhibition proper and the Trocadéro, adjoining the Seine. In the chief building the first thing that struck the eye was the marvellous collection of Potatoes exhibited by Messrs. Carter & Co. and Mr. W. Porter. In comparison with the exhibits of French growers they were as giants to dwarfs, and the admiration of the French public was unbounded. There were collections of 12, 25, and unlimited. In the collections of 12 and 25 Mr. Porter fairly rivalled his great competitor, but was beaten in the collection, as he showed but 62 sorts against 115 to Messrs. Carter. In Mr. Porter's 12 were International, Blanchard, Brese's Prolific, Climax, Snowflake, Brownell's Beauty, Improved Ashtop Fluke, Napoleon, Radstock Beauty, Early King, Porter's Excelsior, and Crimson Walnut Leaf. In Messrs. Carter's twelve were Brownell's Beauty, Ice Cream, Crystal Palace Gem, Idaho, International Kidney, Emerson's Advance, Superior, Schoolmaster, Early Oneida, Snowflake, Grampian, and Waterloo Kidney. The larger collections contained these and the other chief Potatoes in cultivation. The best show of Potatoes by a French cultivator was that exhibited by M. Vilmorin, who had an even collection of 272 sorts. There were many large collections of fruits, notably M. Leroy's 330 plates of Apples, M. Croux's collection of Peaches, M. J. Margottin's collection of Grapes in pots, M. Oudin's collection of 700 sorts of Apples, chiefly cider fruit; some wonderful Strawberries fruiting four times a year, and many other objects of interest, which would require the whole fortnight the Show is open even to superficial study.—LEWIS A. KILLICK, Langley, Maidstone.

ROSES FOR THE MILLION.

THE million are growers of Roses not for exhibition, but because the Rose of all flowers is the most ornamental, sweetest scented, and most pleasing for bouquets. The election of Roses recorded in your number, September 26th, is an election by exhibitors. Many Roses which ought to be in every garden are omitted as, I suppose, not deserving a place at an exhibition; such as Souvenir de Malmaison, Baron Prévost, Général Jacqueminot, Géant des Batailles, &c. I would suggest an election of Roses most suitable for the garden of the million. 1, The freest bloomers; 2, Hardest; 3, Best for bouquets. Such an election I am sure would be of use to the readers of the *Cottage Gardener*.—ONE OF THE MILLION.

STRAWBERRY GROWING AT SARISBURY, HANTS.

AT Sarisbury in the parish of Titchfield, Hants, about midway between Southampton and Portsmouth, where there is a fine and extensive village green much resorted to by cricketers of the locality, the culture of Strawberries for market is carried on upon an extensive scale, and on land which at first sight would hardly be deemed good enough for the most moderate feeding garden crop; and as it is generally understood that the Strawberry is a gross feeder and requires a fat loamy soil, I was surprised to see broken-up heath land, which a short time previously was growing scarcely anything but furze and heather, covered with strong and healthy-looking Strawberry plants, my visit having been made after the crop of fruit was gathered. I was informed that in this locality almost the earliest Strawberries which reach Covent Garden are grown, and that during the past season upwards of 300 tons of that fruit were sent from the district (which hardly exceeds a square mile) to Covent Garden, Manchester, and other markets.

The adaptability of the soil to the growth of the Strawberry seems to have been a surprise even to the inhabitants, and it is only within a very few years that such an important culture has been so largely developed. Some seven or eight years ago the agent of the principal owner of land in the village, being

dissatisfied with the farming of a piece of heath land, which has a considerable slope towards the north-east, resolved to let it out to cottagers at moderate rents in allotments. The soil of this piece, and of the district generally where the best fruit is produced, consists of a sandy peat mixed largely with small flint stones varying in size from a walnut to a hen's egg, and contains very little loam. The subsoil is sand and gravel, but as brick earth is obtained in the locality it is probable it underlies the gravel at no great depth. The surface in many places is almost white with flints, and a more uninviting material for gardening can hardly be conceived. It seems that an intelligent cottager, having noticed that Strawberries prospered in a market garden in the locality, tried the experiment on a small scale on his allotment. Success attending the experiment he extended it, his neighbours watched and followed suit, and the Strawberry fever quickly became infectious. At the present time nearly the whole field, probably containing 15 acres, is devoted to Strawberries, and most of the available land with nearly every nook and corner in the village from a road upwards is appropriated to the culture of that fruit. Gooseberries, Currants, Cherries, Apples, and Pears are also grown to a small extent, and in some instances with tolerable success; but a first glance is sufficient to show that these fruits, except perhaps the Cherry, are more at home in Kent and elsewhere than at Sarisbury.

The course of Strawberry culture is somewhat as follows:—As early as possible in the season strong runners from fruiting plants are laid in, and about the last week in August or early in September, being then well rooted, they are transplanted in rows from 2 feet 6 inches to 3 feet apart, and about 18 inches in the rows; in some cases, however, the plants are put in about 2 feet 3 inches apart all ways, each plan having its adherents and appearing equally successful in its results. Early planting is not resorted to on account of the difficulties and expense attending the artificial watering of the plants, but the work is deferred until the weather is somewhat cool, and in order that the newly-put-out plants may have the benefit of the autumn rains. My informant, an intelligent cottager, who was one of the first to adopt extensive culture of the Strawberry, stated that not only at planting time but afterwards those Strawberries on ground which contained the most flints did the best, the stones helping to check evaporation, to keep the ground cool and at an equable temperature, and the plants firm in the ground. The suggestion seemed an intelligible one, and leads almost to the conclusion that a mulching of stones would often be beneficial to other crops and plants as well as Strawberries, and recalled to my mind instances where Roses, climbers and trees, prospered with the material portion of their roots beneath a paved surface. On stronger and loamy land free from flints I was told that the crop of Strawberries was not profitable. As the plants at Sarisbury are put in late the produce of fruit the next year is small, and that of the third year is considered the largest and best. The same plants are usually retained for four or five years, but sometimes until the seventh; the ground is then dug over, manured, and replanted with Strawberries again.

The sorts grown are Sir Joseph Paxton and Alice Maud. British Queen and Elton Pine are also partially cultivated, but neither so profitably as the two first, although the Queen appears to succeed on the soil. Elton Pine is, however, being abandoned *in toto*, as the success of the Sarisbury growers is a good deal owing to the precocity of the crop, Strawberries from Sarisbury getting into Covent Garden a few days after those from Cornwall, and preceding the Kentish by nearly a fortnight.

It is said that a good crop has produced as much as £150 per acre, the cost of labour, marketing, manure, and other expenses amounting to about £50 an acre per annum. Mulching with dry littery manure is resorted to as soon as the fruit begins to swell, and after the crop is gathered the plants are lightly forked between. Stable manure is obtained from Southampton and Portsmouth by the river Hamble, which is navigable to the lower part of the village, but as the rise is considerable the cost of haulage is proportionally large. I fear, however, that without a liberal supply of this in hot dry seasons, such as those of 1868 and 1870, Strawberries on Sarisbury land would be a failure.

The village is dry and elevated, and from it views may be obtained on the one side of St. Cross at Winchester, and on the other of Southampton Water and the Isle of Wight. The Oak, Laurel, Cherry, Rhododendron, and Fuchsia Riccartoni seem to flourish in the locality, and since the cultivation of the

Strawberry has become general the price of land has increased largely, and for the same land a rental of £4 instead of £1 per acre may now be obtained. It is rarely that a new industry is so rapidly developed, and it is not often in this country that the agricultural wheels can be so easily turned into horticultural ruts, and in these days of unprofitable farming a further extension of fruit farming to such crops as the Strawberry would be of advantage to the community; and as neither the sunny south nor our transatlantic brethren are likely to be competitors in this branch of fruit culture, at all events until veritable travelling Strawberries are produced, Sarisbury may probably look forward to a prosperous future. As English tastes are now, our Strawberries are not likely to be displaced by the Bordeaux Fraises des Quatre Saisons, which, on account of their better travelling qualities and the admirable manner in which they are packed, are the only foreign Strawberries likely to get into our markets.—T. LAXTON, Bedford.

THE WARS OF THE ROSES.

CANON HOLE's position as an exhibitor of Roses is too well known to require any comment from me, but your correspondent, "WYLD SAVAGE," having relegated him to the third rank among exhibitors, and also stated that "It is almost a certainty that Messrs. Baker and Jowitt are first and second at any show," I may state a few facts bearing on the matter. I believe Mr. Hole and Mr. Jowitt have competed together at only four shows within the last three years—viz., Nottingham

in 1876, when Mr. Hole was *facile princeps*, winning £25 in prizes; St. James's Hall, 1877, when Messrs. Jowitt's, Baker's, and Hole's Roses were so nearly equal as to cause the remark, "The Judges cannot make much of a mistake whichever they put first;" the National Society's London Show this year, held at the Crystal Palace, when Mr. Hole was put third to Mr. Jowitt's second; and the National Society's Provincial Show, held at Manchester a week afterwards, when Mr. Hole turned the tables, winning the premier amateur prize, Mr. Jowitt being second: so that as far as those two are concerned it is game and game, and who shall name the winner of the rubber?

As a rule the Caution Roses are not on until Mr. Baker's are over, and the London shows of late years have been held too early for the Nottingham "maidens," but I can testify to their success when pitted against not merely amateurs, but such nurserymen as Cranston of Hereford, Merryweather of Southwell, and Frettingham of Beeston. Possibly "WYLD SAVAGE" may not have attended the Nottingham Shows of 1875 and 1876. Had he been there he would have seen as strong competition as at any of the shows he names, with the exception of the National and Crystal Palace Shows; and being called on to judge at both Nottingham and the National, I can say that the blooms staged at Nottingham were equal, and in some of the smaller classes superior, to those exhibited in London. I do not for a moment wish to disparage the Roses of my good friends Messrs. Baker and Jowitt, but I feel confident that when Caution is in bloom Mr. Hole can hold his own with either or both of "WYLD SAVAGE's" "giants."—FENMAN.

PSYLLIODES CHRYSOCEPHALA—A NEW ENEMY OF THE TURNIP.

IN the October number of the "Entomologist," Mr. E. O. Ormerod publishes his observations upon the above species, concerning which he says—"About March 18th of the present year, whilst examining a bed of white Turnips running up into flowering stems in my garden near Isleworth, I noticed that many of the shoots were channelled internally by small grubs. In some cases these galleries appeared only just begun, and were still only horizontal piercings of distances along the stem, with the larva occupying more than half the length of the tunnel, but more frequently, judging by the discoloration and the progress of the injury, the work had been commenced some time before at the ground level, and had been carried thence some inches up the stem, occasionally diverging into the petiole of the leaf, and later on the larval workings were to be found both in the centre and beneath the ring of the bulb itself. The bed of Turnips, as well as some others in the neighbourhood, proved greatly infested. Of thirteen plants brought in for examination only one proved free from attack, but the larvæ were not numerous in each plant; sometimes as many as three or four were to be found at distances along the galleries, sometimes only a single specimen was discoverable. The injury being new to me I isolated some plants with the larvæ, which developed about the beginning of June into the well-known beetle *Psylliodes chrysocephala*, distinguishable from its near allies the Turnip beetles technically by peculiarity of the antennæ and posterior tarsi, and to general observation by the rather larger size, robust form, and even greater saltating powers." Mr. Ormerod then minutely describes the larva and pupa, concluding with the statement that, though this enemy is not one likely to prove markedly injurious, it should be promptly extirpated where noticed by burning infested bulbs or opening-up the ground to insectivorous birds.

MIXED PLANTING OF FLOWER BEDS.

SOME of the prettiest and most chaste arrangements in the planting of flower beds are to be found in those planted with two or more kinds of plants in mixture. In those gardens where there is not much space at command for securing variety year after year, and more especially in gardens where the working staff is not sufficient for the wants of the place, the practice of employing mixtures in planting the flower garden becomes a matter of some importance, but even in the most pretentious gardens a few beds or borders in mixture lend an added attraction.

There are some recognised styles of planting—such, which have been in use for many years, as mixing *Geranium Mangles'* Variegated with *Verbena Purple King*, and *Polemonium cæruleum* variegatum with blue *Lobelia*. One of the most telling

beds I have seen this season was a mixture of *Geranium Flower of Spring* and *Viola The Tory*. The deep purple of the *Viola* and the flower of the *Geranium* told wonderfully, the white of the foliage giving a most chaste appearance to the whole bed; but it is in light mixture that the happiest effects are produced. A narrow border I saw a few weeks ago planted with *Lobelia Lady Macdonald*, a variety very similar to *Paxtoni*, and a very few plants of the old *Verbena* *melindres splendens* dotted amongst them, made a very happy effect. Two large beds, which have attracted great attention, from lady visitors especially, we have this season planted with a mixture of *Geranium Flower of Spring* and *Koniga variegata* in mixture. A narrow band of *Perilla nankinensis* divides these from an edging of *Geranium Mangles'* Variegated. Masses of scarlet *Geraniums* or yellow *Calceolarias* attract no attention compared with these beds. Another simple mixture, which has given great satisfaction this year, is the front portion of two broad borders, and planted as follows:—The edging line of *Dactylis elegantissima* alternately with *Viola Sir Walter Scott*, then a line of *Festuca glauca*, then two lines of the *Dactylis* mixed with *Verbena pulchella*, then another line of the *Festuca*, and a line of *Dactylis* alternately with *Viola Alpha*. The material in this case is of the commonest, and the effect excellent.

Very effective single rows may be formed of yellow, purple, and white *Violas*, of pink, scarlet, and variegated *Geraniums*, and of *Perilla*, *Calceolaria* (yellow), and *Cineraria maritima*. Such rows are especially suitable for small places where a few plants of a kind may be turned thus to the best advantage without in any degree lessening the effect of the whole. As arrangements for next season's planting should either have been made or in progress, these hints on a simple and effective mode of planting beds and borders may be of use. One of the most prominent beds in the flower garden here will next season be planted with *Geranium Flower of Spring* and *Viola Duchess of Sutherland* (very light blue) in the main block.—R. P. BROTHERTON, *Tynningham*.

[We have seen such mixtures as those described, and they were very beautiful and much admired.—EDS.]

WORK FOR THE WEEK.

KITCHEN GARDEN.

Lettuces for Early Spring.—Plant out at once Lettuces from the August sowings. If the soil be light it must be made firm by treading. A south border should be chosen, or failing that an east border or a warm situation, planting in rows a foot apart and the plants 6 inches asunder, with a view to every other plant in the rows being cut for very early use. South borders are of such value for early produce that large extents cannot be set apart for particular crops. We therefore plant the Lettuces where we shall presently sow early Peas in rows 4 feet apart, having a row of Cabbage Lettuce on each side of the rows of Peas and 1 foot from them, with a row of the *Cos* varieties in the centre—i.e., two rows of Cabbage and one row of *Cos* between each two rows of Peas. The small plants of the *Cos* varieties of Lettuce left after planting out should be pricked-out in a bed in a sheltered situation, and they will be serviceable for spring planting. We plant at this time Lettuces from the August sowings in frames, *Cos* at 1 foot distance apart, *Bath Sugarloaf* being preferred, and between each row *Commodore Nutt*, *Early Paris Market*, or *All the Year Round* Cabbage varieties; the Cabbage Lettuces being cut when young do not interfere with the *Cos* varieties. These come in before those in the open ground, it hardly being possible to have too much early salading. Accommodation must be at once provided for Lettuces and Endives, which are to be lifted from the open ground to continue the succession when the supply from the open ground is over. Allow no opportunity to pass without giving attention to earthing-up Celery requiring it.

Complete the pricking-off of Cauliflowers in frames or under handlights, it being important that in the case of both these and Lettuces that they have full exposure, the lights only being employed in case of very heavy rains (then tilted) and in case of frost. Those whose frame space is limited should prick-off a good breadth of Cauliflower in a border 18 to 24 inches wide in front of a south wall, and they frequently winter as well as those in frames. Pay strict attention to Cauliflowers which are fit for use in taking them up in case of frost and laying them in pits or sheds, when the heads will remain in condition for some time.

HARDY FRUIT GARDEN.

Filberts and Nuts should be gathered, spreading them very thinly upon shelves in an airy room, but not removing the husks, as for a time the nuts are placed upon the table in their natural covering. Push forward the making of fruit borders, having all in readiness so that there may not be any delay in planting so soon as the trees come to hand. An early choice of trees at the nursery is important, and of equal importance is it to have the trees

carefully taken up with the loss of as few roots as possible, neither should they be exposed to the atmosphere so as to become dry. In the selection of trees for walls choose young trees, not those that have been repeatedly headed back, for though they may have stronger and more shoots than two-year-old trees, their roots are very much more extended and comparatively devoid of fibres. The fan shape is the best, it being important the shoots be moderately strong and equal, or nearly so, in strength, for if the shoots on one side of the tree be stronger than the other it is hardly practicable to secure well-balanced form in the specimen; they must also be clean and well ripened. If the wood be sappy and green and has the least trace of mildew, gum, or canker, pass such trees by; they are dear at any price. A fan-trained tree should have five shoots, more not being objectionable provided they are not the result of frequent headings and are evenly balanced.

Selection of Fruits for Various Aspects.—South walls are suitable for Apricots, Peaches, and Nectarines, and a tree or two of Cherries and Plums which it is desired to have early. Of Apricots, Oullins Early, Peach, New Large Early, Kaisha, Hemskerk, St. Ambroise, Moor Park, and Belle de Toulouse are good; Breda, Shipley's, and Royal having firmer flesh are only desirable for preserving, not being nearly so rich as the others. Peaches.—Early Beatrice, Hale's Early, Dr. Hogg, Early York, Grosse Mignonne, Royal George, Noblesse, Violette Hâtive, Raemackers (a form of Noblesse, later and higher-coloured), Barrington, Walburton Admirable, Lord Palmerston, and Radclyffe form a good succession. Nectarines.—Lord Napier, Rivers' Orange, Stanwick Elruge, Elruge, Violette Hâtive, Rivers' White, Hardwick, and Albert Victor. Three Plums for a south wall are July Green Gage, De Montford, and Green Gage. Three Cherries.—Early Jaboulay, Black Tartarian, and May Duke. If greater variety is wanted Early Red Bigarreau, Governor Wood, and Elton may be added. Half a dozen Pears for a similar position are Summer Doyenné (Doyenné d'Été), Beurré de l'Assomption, Jargonelle, Clapp's Favorite, Souvenir du Congrès, and Beurré d'Amanlis. Pears are much finer in appearance when grown against a south wall; but as a rule they should be gathered so soon as indications of ripening commence, as they are often mealy if left upon the trees until fully ripe. Figs do well against a south wall: Brown Turkey, White Marselles, and Brunswick are the best. East walls answer admirably for Plums: Denniston's Superb, Huling's Superb, Jefferson, Kirke's, Transparent Gage, Coe's Golden Drop, Purple Gage, Blue Impératrice, Ickworth Impératrice, Reine Claude de Bavay, Guthrie's Late Green, and Late Rivers are all good dessert kinds. Culinary Plums.—Early Rivers, Early Orleans, Orleans, Prince of Wales, Prince Englebert, Victoria, Pond's Seedling, White Magnum Bonum, and Belle de Septembre. East walls answer well for Cherries: good sorts are Belle d'Orleans, Werder's Early Black, Frogmore Early, Black Eagle, Reine Hortense, Mary, Late Duke, Bigarreau Napoleon, and Büttner's Yellow. The Plums and Cherries named for a south wall answer well for an east aspect. West walls suit Pears.—White Doyenné, Beurré Superfin, Marie Louise d'Uccle, Durandau, Doyenné du Comice, Conseiller de Cour, Marie Louise, Thompson's, Beurré Diel, Van Mons Léon le Clerc, Passe Colmar, Beurré Bachelier, Beurré d'Arenberg, Glou Morceau, Knight's Monarch, Winter Nelis, Joséphine de Malines, Beurré Sterckmans, Beurré Rance, Ne Plus Meuris, Bergamotte Esperen, Passe Crassane, Van de Weyer Bates and Basiner. North walls are suitable for the Morello Cherry, which should be the principal tree employed; but other Cherries succeed—viz., Early Red Bigarreau, May Duke, Governor Wood, and Elton. Pears.—Jargonelle, Williams' Bon Chrétien, Comte de Lamy, Marie Louise, and Beurré Diel. Plums.—Victoria, Jefferson, White Magnum Bonum, and Blue Perdrigon. North walls are available for Red and White Currants.

Distances for Planting Wall Trees.—The distances at which wall trees should be planted depends upon the height of the wall and upon what stock the trees are. Pears against a 12-foot wall should be planted 24 feet apart, a 10-foot 30 feet, or a yard less of lateral extension for every foot decrease in height of wall; Apricots 21 feet apart upon a 12-foot wall and 24 feet upon a wall 10 feet high. Plums and Cherries the same as Apricots. Peaches and Nectarines 20 feet upon a 12-foot wall, and 24 feet apart upon a 10-foot wall. Figs should be planted 18 feet apart upon a 12-foot wall, and 21 feet apart upon a 10-foot wall. Apples are well worth a place against east or west walls in cold localities—viz., Golden Pippin, Ribston Pippin, Pearson's Plate, Adam's Pearmain, Scarlet Nonpareil, Braddick's Nonpareil, Margil, Pennington's Seedling, Downton Pippin, Barcelona Pearmain, Bess Pool, Golden Russet, Sturmer Pippin, Cox's Orange Pippin, Duke of Devonshire, Lord Burghley, Ashmead's Kernel, and Wyken Pippin. They require to be planted the same distance apart as Pears, and succeed, like them, either trained fan or horizontal. Apples and Pears upon the dwarfing stocks—i.e., Paradise and Quince respectively, horizontally trained, may be planted 12 feet apart for walls 8 to 10 feet high; but upright-trained trees are more suitable, planting them 6 feet apart for a wall of 8 feet, and 3 or 4 feet apart for one of 10 to 12 feet.

FRUIT HOUSES.

Vines.—Late Grapes will be thoroughly ripe, they having been

hastened in spring by the aid of fire heat, which is much preferable to having, after October comes in, to maintain a forcing temperature to secure the ripening of the fruit. In the latter case the temperature must not be less than 70° to 65° at night, 75° to 70° by day, with a rise of 10° to 15° with sun until the Grapes are ripe; at least the fires must be kept going until the wood is brown and hard. The fruit being thoroughly ripe, in which state only can the Grapes be expected to winter satisfactorily, and the wood thoroughly matured, all spray or laterals may be removed down to the main buds, ventilating liberally upon all favourable occasions. Fire heat will then only be necessary to prevent the temperature falling below 50°. To prevent dust settling upon the berries raking or sweeping must not be practised. Mats or dry straw laid over the inside borders will to some extent prevent evaporation, assist in keeping the atmosphere dry, and prevent the soil cracking. The outside borders must, if the fruit is to keep satisfactorily, be covered over, wooden shutters being the best, tarpauling over bracken or straw answering well, or a good thick thatch of bracken or straw will be serviceable. Fermenting material must at once be prepared for placing in houses where early forcing is contemplated, and for covering outside borders about a fortnight prior to closing the house, that for the inside not being placed until starting time. It will aid in the more regular and freer breaking of the Vines. Tree leaves with stable litter in about equal parts thrown into a heap, damped if dry, and turned over once when getting warm, and again damped if necessary, will give a more reliable heat than all dung. If bottom heat can be given the Vines in pots to start them they will mark its appreciation by breaking well. Provided there is a bed of about 3 feet depth and 4 feet or so wide the pots may be raised upon loose bricks in pillar fashion, so that their rims are slightly higher than the pit edge, and so that the pots will be in the centre of the bed. Leaves being put in to fill the pit a gentle warmth will be afforded the Vines, and the roots will pass from the pots into the leaves, deriving support beneficial to the growth of the Vines. The temperature at the roots ought not to exceed 75°, and the top heat 55° to 50° by artificial means, until the eyes swell, then gradually increase it to 65° to 60° when they are breaking. The canes should be depressed to a horizontal position to secure their breaking regularly. Damp the houses and canes morning and afternoon. Young Vines have a disposition to keep on growing to a late period; check them by stopping the shoots moderately, and facilitate the ripening of the wood by a high and dry temperature by day, shutting off the heat and keeping the ventilators open by night.

Cherries.—The trees in pots should be examined. Any that require larger pots should be shifted, disentangling the roots around the sides of the ball with a fork. Trees that are forced annually without being placed in larger pots should have the drainage rectified, a few inches of the soil from the base removed, the roots shortened, and fresh soil given—fibrous loam with about a tenth of road scrapings or old mortar rubbish added, removing also the loose surface soil and replacing with the above compost, with a fifth of well-decayed manure added and a sprinkling of half-inch bones. They may be plunged in a sheltered situation, previously giving them a good watering, and then covering over the surface of the pots with litter. If any trees in the house require to be replaced it should be done directly the leaves have fallen. Trees trained to walls for four to six years are best. Borders 6 feet wide and 2½ deep, well drained, are suitable—indeed better than wider borders. Good turfy loam suits admirably, with an admixture of road scrapings or old mortar rubbish. It should be made tolerably firm. Early Jaboulay, Black Tartarian, May Duke, Early Red Bigarreau, Governor Wood, and Elton, are good sorts for forcing.

PLANT HOUSES.

Orchids.—As the days shorten and the cold increases the temperature must in the various structures also decline. In the East India house a mean of 70° by day and 60° at night will be sufficient; for the Cattleya house 65° by day and 55° at night; the Odontoglossum house 55° by day and 45° by night will be desirable temperatures. Vandas, Aërides, Saccolabiums, and other plants in an active state will require water, but it must not be given in such quantity in July. The moisture must be in proportion to the diminished temperature and ventilation. Very little ventilation will now be necessary except when mild, then a little air may be given. Syringing overhead for the most part will not be required. Dendrobiums, Cattleyas, &c., having completed their growth will require very little water. Calanthes are throwing up their flower spikes and should have every encouragement in the way of heat and moisture, keeping the leaves clean by frequent spongings. Zygopetalums or other plants commencing to grow must be kept moderately moistened, placing where they can have plenty of light and moisture, repotting them if necessary. Plants as they ripen off must be removed to a drier atmosphere. Phalænopses must be very carefully supplied with water, for if the leaves are overcharged with moisture they are liable to rot at this season. Orchids in bloom may be removed to a drier house, and the flowers will last much longer than in a moist atmosphere. Anæctochilus under bellglasses must have the moisture sponged

off the glass every morning, the glass being tilted to admit fresh air, watering very sparingly or the roots will decay. A temperature of 65° to 55° is suitable for them at this season.

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense. Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

BOOKS (J. D.).—Mr. Mechi's book is very reliable, but we know nothing of the other work you speak of. "How to Farm Two Acres Profitably," published at this office, will suit you perhaps. It can be had by post for thirteen postage stamps. (A. B.).—The book entitled "Our Farm Crops" is published by Fullerton, and a copy can be had by ordering through a bookseller. (R. D.).—We know of no book such as you ask for, but our "Garden Manual," price 1s. 6d., contains the information you need. (Jacko).—Our "Garden Manual," 1s. 6d., post free 1s. 9d.; "Indoor Gardening," 1s. 6d., post free 1s. 7½d.; and "Outdoor Gardening," 1s. 6d., post free 1s. 7½d., would suit you. They are published at our office. (Mr. W. Pickup, Waukonit).—There is no English translation of the book you mention. The only complete work on the subject in English is Dr. Hogg's "Fruit Manual."

TO REMOVE THISTLES (A Very Old Subscriber).—There are various kinds of Thistles which infest pasture land, but especially the Spear or Bur-Thistle (*Carduus lanceolatus*), and the Field Thistle (*C. arvensis*). The former being a biennial can more easily be got rid of than the other, by preventing its seeding, and constant eradication. The latter must be continually spudded so as to prevent it making any quantity of leaves, for being a perennial you cannot get rid of it by any other means unless you break-up the pasture, which would never do.

ROSES (J. A. X.).—For exhibition purposes you cannot err by selecting the number you require from the "Rose election" lists, and for garden decoration the Rev. W. F. Radclyffe has submitted an excellent selection in another column.

ROSES DISEASED (W. K.).—All the effects you mention are caused by failure of a supply of sap. Mulch the surface of the soil, and water copiously in dry weather.

GERANIUMS IN SOUTH DEVON (S. H.).—In exceptionally mild winters we have known Geraniums and Calceolarias live without protection, but they do not usually thrive well afterwards. Young plants planted out in the early summer months soon outstrip them. Sometimes the winters there are, as elsewhere, severe. We have known huge bushes of Myrtles killed to the ground which were growing in one of the mildest and most sheltered positions in South Devon.

HARDY FLOWERS (E. P. Y.).—All the plants you mention are hardy.

WORCESTER PEARMAN APPLE (H. F. C.).—We think this excellent Apple is sufficiently hardy for a standard in the south of Scotland. The Pear which you describe is probably the Black Worcester.

CULTURE OF LILY OF THE NILE (Susser).—The roots of *Richardia aethiopica* should not be subjected to a drying-off process at any period of the year. It is a native of Africa, and is found near the Cape, growing abundantly in swamps and pools of water. This fact, together with a knowledge of the seasons of its native habitat, are our best guides to its successful culture. Spring time at the Cape begins in July or early in August, and that is precisely the time when this plant begins to push forth new growth with us. To turn this fact to full account we take care to shake the plants out of the pots in June, to divide them if necessary, and to plant them like Cabbage plants in a rich bed of soil in the open garden. In the north we should lift them and repot at the beginning of September; in the south at the end of that month, leaving the pots out on a bed of coal ashes for a week or two, or rather so long as there is no risk of damage by frost; then they are placed in the greenhouse, and soon begin to flower, and continue doing so long after Christmas if they have plenty of water and occasional doses of liquid manure. When turning out the plants in spring it is our practice to turn our surplus stock to valuable account by planting clumps in streams and ponds wherever the water is deep enough to afford thorough protection to the roots from frost in winter. Such clumps form a prominent and striking feature among our aquatic plants, among which the *Richardia* now ranks as high as it does among pot plants.

CLERMATIS JACKMANI IN BEDS (Idem).—When other plants are planted in a bed of Clematis the only precaution necessary is to see that its roots sustain no injury either from laceration or starvation, which will be best effected by heavy top-dressings of rich soil and the exercise of due care in the planting or clearance of other plants. Bnlbs may be planted in the bed for producing a display in spring, but we do not think that annuals could be grown with the Clematis for flowering late in autumn.

PRESERVING THE AUTUMN-TINTED LEAVES OF VIRGINIAN CREEPER.—A correspondent desires to know the proper mode of preserving the leaves intact. Owing to the formation of the two lower leaves in a group of five the ordinary mode of pressing in a book is fatal, the said lower leaves usually falling off on being flattened.

AGAPANTHUS UMBELLATUS (G. H. F.).—It is a rhizome, and neither a bulb nor a tuber.

STOVE (D. W.).—Write to Mr. T. Read, Engineer, 258, Old Street, London.

TROPÆOLUMS CHANGING COLOUR (R. J. W.).—All florists' varieties raised from seed are liable to vary.

PERENNIALS (H. S. B.).—We scarcely understand your letter, which stipulates for hardy plants "that will flower from Christmas to Michaelmas;" in other words, from the end of December to the end of the September following, excluding those flowering in October, November, and December. If that is what you mean the number is legion. Send to Mr. Ware, Hale Farm

Nurseries, Tottenham, London, for his catalogue of hardy plants. If you state the number of plants you require we shall be glad to aid you.

STRAWBERRY FOR LIGHT SOIL (P. B.).—President is one of the best varieties for light soil. Garibaldi also usually succeeds well on any fertile soil.

OSAGE ORANGE.—"South American" wishes to know where he could obtain seeds of this shrub, and how to raise a fence of it.

ROSES (J. R. C.).—When beginning to start in the spring water copiously once a week with weak liquid manure; it will impart vigour to the trees.

COMPOST FOR VINE BORDER (Jacko).—Turfy loam taken from a pasture 3 inches thick with its turf or not deeper than 6 inches, and where the soil is light preferably to heavy. This should be laid in a heap until the turf is reduced, then chopped up not very small, adding a tenth part of old mortar rubbish and a twentieth part of half-inch bones. If you use heavy clay soil add a sixth of old mortar rubbish, a tenth of charcoal, and a like quantity of charred vegetable refuse, and a fourth of fresh stable manure with the straw shaken out. The depth should be 2 feet 6 inches, and at a bottom of the border have 9 to 12-inch drainage of stones or bricks. The same soil would grow Roses, but it is not desirable to have them in the same house.

COMPOST FOR PEACHES (Idem).—Strong loam is most suitable with an admixture of about a tenth part of old mortar rubbish or chalk. Your clayey soil would grow them well, it being well drained, the border being 2 feet 6 inches deep. Roses would do better with them than with Vines.

CUCUMBERS AND MELONS IN GREENHOUSE (Idem).—In summer they would succeed, provided they were kept in a temperature and moisture suited to their requirements, which is fatal to greenhouse plants. It is not necessary to have water between the top of the flue and the soil, but a foot in thickness of rubble to prevent the due heat burning the roots. Turfy loam is a suitable compost, that for Melons being preferably heavy.

GREENHOUSE (Cottager).—If you have a wall the cheapest form of house would be a lean-to without front lights, which would not require more than three openings at the top for ventilation of about 3 feet by 2 feet. It would not be practicable to grow Cucumbers profitably along with plants unless you had the house for wintering Pelargoniums and other bedding-out plants in winter, and after the middle of May occupy it with Cucumbers. Competition is now so keen that unless you give in the labour there is little prospect of profit.

ROSES IN POTS UNDER GLASS (W. H.).—Tea Roses would answer admirably, training them to the rafters of the house as proposed. The weak growers would not be suitable, but the following would answer:—Marie Sisley, Madame Willermoz, Niphetos, Sombreuil, Madame Bravy, La Boule d'Or, Madame Jules Margottin, Madame de St. Joseph, Duchess of Edinburgh, Adam, Catherine Mermet, Coquette de Lyon, Céline Forestier, Belle Lyonnaise, Amazone, Comte de Paris, Safrano, and Marie Van Houtte. Maréchal Niel must not be omitted.

FORM OF KITCHEN GARDEN (J. F.).—For the size you name we should prefer the square to a parallelogram, as the width of the latter is so disproportionate to the length; 60 yards long and 40 yards in breadth would be better, which we recommend preferably to the square, though that would answer well. Brick walls are most suitable; concrete walls we have no experience of. Pears for standards are Jargonelle, Williams' Bon Chrétien, Louise Bonne de Jersey, Comte de Lam, Marie Louise, Beurré Diel. Walls.—Our selection would be Marie Louise, Gansel's Bergamot, Beurré Diel, Forelle, Fasse Colmar, Van Mons Leon le Clerc, Glon Morceau, and Bergamotte Esperon. Peaches: Hales' Early, Dr. Hogg, Grosse Mignonne, Belle-garde, and Noblesse. Figs: Brown Turkey and Brunswick.

HEATING HOUSE WITH FLUE (Idem).—It is an impossibility to tell how many cubic feet of air will be heated to a given temperature without knowing the heat of the radiating surface, but we find a flue from a boiler passing through a house 10 to 12 feet in width gives off sufficient heat to exclude frost in a house 20 to 24 feet in length, the flue being raised above the floor and having all its surfaces exposed.

CLIMBERS FOR WALL IN SMOKY LOCALITY (C. H. J.).—Ivy is the best of all, choosing for so low a wall the small-leaved varieties, as *Hedera dentata*, *Donairensis*, *rhomboida obovata* and its variegated form *guttata-folia*, *elegantissima*, *taurica*, and *tricolor variegata*. Clematises also do well.—Albert Victor, Lady Londesborough, Miss Bateman, Jackmanii, Lawsoniana, and Lucy Lemoine. Honeysuckles.—Scarlet Trumpet, Early White Dutch, and *flexuosa*. *Jasminum nudiflorum*, *J. officinale*, *Kerria japonica*, *Ligustrum japonicum*, and *Ampelopsis Veitchii*. Those marked with a star for the south wall along with Tea Roses *Souvenir d'Elise*, Madame de St. Joseph, Madame Jules Margottin, Madame Willermoz, Homère, Marie Sisley, Madame Berard, Marie Van Houtte, Duchess of Edinburgh, Comte de Paris, and Céline Forestier. Roses do not do well in smoky districts; a few of the best are Alfred Colomb, John Hopper, Charles Lefebvre, Sénateur Vaisse, Madame Victor Verdier, Baronne de Rothschild, Boule de Neige, Auguste Neumann, Claude Levet, François Michelon, Général Jacqueminot, La France, Jean Dalmati, Dupuy Jamin, François Courtin, Leopold II., Felicien David, Claude Levet, Baronne Louise Uxkull, Madame Clert, Louise Wood, Maréchal Vaillant, Thomas Methven, Olga Marix (all Hybrid Perpetuals), and Gloire de Dijon.

FORMING CROQUET GROUND (Amateur).—Turn up the whole of the ground and remove the roots of the weeds of a perennial character, and, making the surface even, lay the part intended for croquet ground with turf, which is preferable to sowing with grass seeds.

ROSES FOR ELEVATED POSITION (Portmore).—Over 500 feet above sea level we have Hybrid Perpetuals Alfred Colomb, Annie Laxton, Baronne de Rothschild, Baronne Louise Uxkull, Bessie Johnson, Boule de Neige, Capitaine Christy, Charles Lefebvre, Claude Levet, Comtesse de Chabillant, Comtesse d'Oxford, Duke of Edinburgh, Edouard Morren, Elie Morel, Dupuy Jamin, Etienne Dupuy, Felicien David, François Courtin, François Michelon, Général Jacqueminot, John Hopper, La France, Lord Raglan, Louis Van Houtte, Madame Clert, Madame Lacharme, Madame Laurent, Madame Victor Verdier, Maréchal Vaillant, Mrs. Veitch, Olga Marix, Prince Camille de Rohan, Princess Beatrice, Sénateur Vaisse, Thomas Methven, Thomas Mills, Princesse Antoinette Strozio, Mary Turner, Miss Hassard, Comtesse de Serenye, Arthur Oger, and many more, but those succeed best. Bourbons—Armoss, Baronne Gonella, Sir Joseph Paxton; and Tea Gloire de Dijon.

PEARS DECAYING (H. N.).—They have probably been left too long on the trees. The specimen sent is scarcely recognisable, but we think it is Beurré d'Amanlis.

LOMBARDY POPLAR STEMS DAMAGED (*Poplar*).—The trees that have been scrubbed halfway through the stems would be better removed and replaced by fresh trees, as if left they would be liable to have the heads snapped off at the wounded part by high winds.

HOUSES FOR GROWING SMALL PLANTS (*S.H.*).—The best form of house is the span without side lights, having ventilation only at the upper part of the roof, and a pathway up the centre about 2 feet wide, and a bed on each side of 4 feet width. It is sufficient if the roof has a fall of 1 foot in 3 feet. The side walls need not be more than 2 feet 6 inches high. A sunken path will give all the head-room required. Shelves may be put up, but they are more injurious than otherwise, as the drip from the pots in watering is injurious to the plants under the shelves.

SELECT PHLOXES (*H. E. B.*).—*Early-flowering*: A. McKinnon, rosy purple, crimson eye; Magnum Bonum, rosy crimson, rose eye; The Shah, rosy purple; John Watson, white, shaded rose, crimson eye; Miss Robertson, white; Mrs. Thorn, white, crimson eye; Perfection, white, rose eye; Duchess of Athol, white, rosy crimson eye; Rosy Circle, rosy lilac; Archibald McKeith, rosy purple; Miss Doig, white, shaded rose, crimson eye; and Elvina, rosy crimson, dark eye. *Late*: D. P. Laird, rosy lilac, crimson eye; Lothair, light scarlet, shaded purplish violet; Madame Damage, white, marked purple; Mrs. Standing, pale rose, rosy crimson eye; Monsieur Delamore, red, black centre; Regalia, rosy crimson, dark eye; James Allan, salmon scarlet, crimson eye; Lady Middleton, white, rosy crimson eye; Flora McNab, rosy pink, magenta eye; Monsieur Hugh Low, red purple; White Lady; Aurora Boreale, salmon vermillion; Rev. W. Baillie, rosy purple, crimson eye. There is not much difference in the height, which depends considerably upon the richness and moisture of the soil. Spring is the best time to plant, doing so early before much growth is made.

CHRYSANTHEMUM BUDS DESTROYED (*W. T. F. M. J.*).—We should attribute the loss of the buds to some caterpillar, which frequently does considerable mischief. They are usually secreted in the centre of the shoots among the leaves, feeding upon the buds. We cannot form an opinion of what the small grubs are to which you refer.

PRECEDENCY (*W. K.*).—We cannot undertake to answer the question.

NAMES OF FRUITS (*Lady M. T.*).—The two Apples sent are the *Ross* and *Nonpareil*.

NAMES OF PLANTS (*L. Hanson*).—We do not recognise the specimen. Leave your Rose buds till the spring before cutting the Briars back. (*Ramalis*).—*Nephrolepis exaltatum*. The small white dots are young sori. (*A. B.*).—1, *Adiantum concinnum latum*; 2, *A. trapeziforme*; 3, *Phlebodium aureum*; 4, *Pteris serrulata cristata*. (*A. L.*).—*Pyrethrum uliginosum*.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

STORING AND PRESERVATION OF ROOTS.

THE cost and charges in various ways of producing root crops are so great that it is of the utmost importance the roots should be as carefully and economically preserved as possible, not only when they may be required for the stall feeding of fatting bullocks or dairy cows, young stock, &c., but also when they are to be fed by sheep in the open fields. We will first consider the question of storing for the winter feeding of horses, cattle, pigs, &c., as being the most important and leading branch of the subject. The growth of roots for consumption on the home farm has much extended during the last ten or twelve years in consequence of the greatly increased number of cows kept for dairy and milking purposes. Mangolds with a portion of carrots upon the sandy soils are now generally grown with the view of being stored for use during the winter and spring months, the mangold being required for general purposes on the home farm; but carrots are required for use first, as they do not keep so well as mangolds, besides which they gain nothing by keeping, and are excellent food at any period of their growth; whereas mangolds not only keep well but improve by keeping when properly preserved by careful storing at the right time. The best time to commence storing mangolds on the home farm is what we have first to consider, for these suffer more from frost than any other roots. The best time for lifting mangolds is from the 20th of October to the 1st of November. It is, however, a question of early or late sowing, for when sown early the crop may be sufficiently ripe for storing the second week of October; if sown late the roots will not be ripe in the second week of November. But this matter in a late crop should not be allowed to interfere with the taking-up; for they will always keep better in heap or store if they are unripe. We have often noticed that ripe roots in the work of carting receive blows and bruises which leave a black mark, and sometimes decay ensues in the heap; on the other hand, when the roots are growing and unripe at storing time, every bruise or injury the roots receive in lifting or carting will heal in the store,

because vegetation will be partially continued in the heap if the roots have been properly and carefully treated at the time of pulling. This brings us to the point as to how the roots should be treated in taking them out of the land and preparing them for the heap. It is a common practice to let the work of lifting, &c., at so much per acre. It is, however, in such cases often done very roughly and without sufficient care. After pulling the roots, which should be done by hand, instead of cutting off the greens we prefer to have them twisted off, because the heart bud of the plant is then left entire and the bottom of the strong succulent leaves are also twisted off. We find the roots always keep best in this way, because they strike-out some greens in the heap, and, in fact, partially vegetate, which is quite sufficient to heal any bruises they may have received at the time of heaping. Again, when the leaves are twisted off there are no stumps of leaves left as there is when cut off, neither is there any fear of damage to the roots by the decay of leaves or portions of leaves. We never allow a knife to be used either for cutting of greens or rootlets, as the latter are necessary to nourish the bulbs in heap, nor do we object to a portion of earth adhering to the fibrous roots; but when the heaps are opened and the roots prepared and trimmed in readiness for the cutter the earth and trimmings should be preserved as manure, for when artificial manures are used as well as yard dung for the crop there will always be found a portion of the manure attached to the small roots, and quite enough to pay for taking care of, but in case of field-feeding of sheep it should be spread on the land; if at the homestead for bullock feeding it should be added to the manure heap. At the time of lifting the crop we prefer to carry to the heap or store the roots as fast as they are taken out of the ground, and we never think of leaving any pulled roots in the field at night time, because we often get night frosts, which would be of no consequence if the bulbs were not pulled, but when they are left and exposed at night they are sure to suffer more or less damage, for that part of the bulb which grows under the surface is very tender and susceptible of injury by frost. In making store heaps for mangolds it is not of so much consequence as to the size, or width, and height of the heap, but it is more a matter of convenience or economy. The heap may therefore be made 10 or 12 feet wide at bottom, carried up to a point at top, and covered with short straw, rough border grass cut from the fields or plantations, stubble, or seaweed before thatching, the latter being the best of all coverings which we know, requiring no thatch in addition, and less earth as a final covering. We also recommend that at every 2 yards a small drain-pipe should be set on end at the top of the heap, which will allow any undue accumulation of heat to escape. The position of the heap should be a southern aspect, near to a hedge or other shelter. After the bulbs are carted away the greens left on the land may be ploughed-in for manure if the ground is to be sown with wheat immediately after, but when held over the winter for barley or oats we have often folded the sheep on the greens, upon which food they will do very well if they have change of pasture food as well.

We now come to carrots. These require more nicety in the taking-up, for they cannot be pulled by hand like mangolds or turnips. We use for this purpose a steel fork introduced at the side of the plants, press down with one hand, and pull the greens perpendicularly with the other, and only in this way can the roots be lifted without breaking or bruising. We advocate the early raising of the crop whilst the greens are full of growth, as they are a very valuable food for all kinds of stock, especially milch cows and pigs. The greens should be cut off so as not to injure the heart bud, and when making the store heap it should not be more than about 4 or 5 feet wide at bottom, and carried up to a point. Carrots do not require so much covering in heap as mangolds, although the heap may be covered in the same way. When required for sheep feeding in the open fields, as they often are upon the sand soils, they only require to be pitted in the field in the same manner as Swedish turnips. It is, however, of more

necessity because rabbits, hares, &c., injure the crop in a most extraordinary manner if left in the land where they grew.

The preservation of Swedish turnips is of the utmost consequence, and if they are required for feeding bullocks at the home-stead they may be treated in the act of storing the same as mangolds, taking care, however, not to cut off the neck or stem, but to twist off the greens as recommended for mangolds. When the crop is required for feeding sheep in the open field, particularly when the seed has been early sown, it is best to take up the bulbs and cast them into heaps, which may be covered with earth if required to stand the winter, otherwise we often take them up and prepare them ready for the cutter about two or three weeks in advance of the sheep. We have found that early-sown Swedes will often rot in the land if not heaped and covered, or pitted as it is termed, besides which adjoining farms may be game preserves; in which case if the roots are left in the land, although they may not rot, yet the injury by hares and rabbits will be great. When they are pitted properly, or a deep double furrow ploughed to bury them in and earthed over in good season, they are safe against all casualties; besides which, if we wish to obtain the full feeding value of the roots they should be taken up at an early period, especially if the leaves are mildeyed, otherwise they lose their feeding properties. The hybrid turnips and the common varieties suffer in a much greater proportion than Swedes from the causes above stated if they are early sown; but as it is usual to sow these sorts of turnips later they will generally retain their feeding value until required for use, and are seldom stored, for they are generally consumed before the frost interferes with the feeding process.

WORK ON THE HOME FARM.

Horse Labour is now at its utmost value, as all the most important tillage work of the year is now in progress, amongst which is the continuation of autumn tillage of the stubbles upon land intended for root crops next year, or for barley in the spring; also the sowing of rye, winter vetches, and trifolium if not already sown, or if failed in plant, must be sown again, the sooner the better, with an increased quantity of seed, and not less than 25 lbs. per acre. The rye and winter vetches should not have the land worked too fine, as when left a little cloddy it takes the frost of winter better, and the plants are somewhat sheltered; but in land where small ridges prevail the land furrows should be struck out with the double mould-board plough and well water-furrowed. Some of the horses may be employed in drawing manure from the home-farm yard or from mixen and laying out upon the clover leas in readiness for ploughing for wheat; also the guano or artificial manures required for wheat should be obtained and brought from town or station in order that the guano may be properly broken ready for sowing. We, however, prefer to have it broken at the factory with their powerful bone mill, as the farm labourers scarcely ever break it fine enough, even when they have proper implements for doing it. Damp ashes should also be provided for mixing with guano for sowing to prevent its flying before the wind, as we always recommend guano to be sown broadcast in preference to drilling with corn; we also recommend that artificial manures should be sown on the fallows after peas, turnips, &c., so that the dung may be laid and spread upon the clover lea. We find that 3 cwt. per acre of the best Peruvian guano is a sufficient dressing for wheat upon well-tilled land, and will produce a full bulk of straw. The odd horse or horses will be employed in carting couch and stubble from the fields undergoing autumn fallowing, also in carting the daily supply of green fodder for soiling horses, cows, &c., there being still a cutting of clover upon most home farms either on the land coming in for wheat or upon the land seeded to clover after the Lent corn, there being an unusual growth of latter grass this year—in fact, we have now grass fit for cutting for soiling cattle in the meadows, where they have not been fed since hay time, and we hesitated whether to feed it or cut up for soiling, but decided upon the latter. Hedge trimmings should also be carted to heap and burned, so as to be out of the way at ploughing time.

Hand Labour consists of winnowing corn both of oats and barley, but wheat may probably improve in condition by remaining awhile in stack as the harvest has been very stormy; men will also be employed spreading dung on the clover leas, filling dung cart, mixing guano and ashes, trimming out the ditches and examining the outfalls of draining, stacking and thatching the ricks of barley and oat straw for fodder. The cattle man must pay attention to the weather, so that if night frosts commence the cattle should lie in a high and dry pasture at night, or else in a well-littered cattle yard and sheds; and if feeding for the butcher they should have an allowance of oilcake mixed with the chaff and cavings from the barley and oat ricks; the young steers also should be cared for at night and not allowed to be in meadows below the fog level, and need also receive some decorticated cotton cake with chaff in their night lair. Shepherds will now be engaged with the management required for the different flocks. The breeding Down ewes must have a constant change, but the keep should be bare. The store tegs should have better food with a change to turnips behind the fattening sheep, the best clover seeds being fed

during the day by the sheep intended for the butcher, and at night a fold of turnips, rape, or cabbage, with an allowance of cotton cake and hay or straw chaff. If only hay is allowed and no cake the turnips should be prepared by women and passed through Gardener's cutter for trough-feeding.

THE POULTRY CLUB.

A COMMITTEE MEETING of the Poultry Club was held on the 25th ult. at the Charing Cross Hotel. Present, R. A. Boissier, T. C. Burnell, R. E. Horsfall, S. Matthew, and O. E. Crasswell (Hon. Secretary). The following Members were elected:—Charles Atkinson, Highborn, Armley, Leeds; H. Evans Broad, The Plantations, Warrington, Surrey; Mrs. Cross, Appleby Vicarage, Brigg; John B. Compton, Hallyburton, Coupar Angus, N.B.; Rev. Gonold S. Davies, Charterhouse, Godalming; Mrs. Hall, Dancer's Hill House, Barnet; Captain John N. Preston, Flasby Hall, Gargrave, Leeds; J. R. Rodbard, Aldwick Court, Wroughton, Somerset; Miss Agnes Sharp, Culverden Hill, Tunbridge Wells; and Rev. J. P. Wright, Newborough Vicarage, Derby; and the following Associate Members:—Rev. E. Bartrum, Berkhamstead, Herts; W. Biddle, 27, Meriden Street, Birmingham; William Johnson, jun., Vostersberg, Cork; G. H. Lawrence, Morant's Court, Sevenoaks; P. H. Le Sueur, Grandvale, Jersey; Edward Morgan, 68, High Street, Hastings; J. S. Playfoot, Dorking; Mrs. Troughton, Garthwyd Hall, Montgomeryshire; and Mrs. M. A. Wilson, Westal, Cheltenham.

Representations from various individuals against a person who advertised eggs were taken into consideration. Apparently he advertised his own at a high price, but sent inferior ones direct from another advertiser of cheap eggs to purchasers. The Secretary was instructed to ask for an explanation.

A letter from Mr. Norwood of Salisbury was read to the Meeting, stating that in his opinion the trimming of the crests of White-crested Black Polands should be recognised, as is the trimming and dubbing of Spanish and Game; and that as with them the question as to whether the trimming was overdone or not should be left to the decision of the judge. The answer given was as follows:—The Committee decide that they cannot give their approval to the trimming of Black Polands' crests as suggested. Wishing as much as possible to discourage trimming in every form, they would suggest to judges that they should not give too much weight to a small amount of black in a white crest, and are content to leave the matter, as heretofore, to their decision.

The following resolution was passed:—That the subscriptions of Members and Associate Members who shall join the Club after the 1st of November, 1878, shall be held to cover all subscriptions due up to the end of 1879.

As at the time of the Meeting it seemed certain that the Oxford Show would fall through, the following resolution was passed, and the Secretary was instructed to forward it to the Oxford Committee:—That the Committee of the Poultry Club hear with regret of the discontinuance of the Oxford Poultry Show, which has always been characterised by good management and prompt settlement; and that the thanks of the Committee of the Poultry Club, on behalf of exhibitors, be tendered to the managers of the late Shows for their gratuitous services during the last six years.

The "Rules for the Management of Poultry Shows," published not long since, were then discussed, and in their present form rescinded, it being decided that many of them might more appropriately be incorporated with certain alterations in the general rules of the Club. The following six rules were agreed upon to be necessarily inserted in the schedule of all shows held under the patronage of the Club:—1. Any exhibitor who has been disqualified by the Committee of the Poultry Club for fraudulent practices is ineligible to compete at this show. 2. No person is allowed to exhibit borrowed birds. 3. Exhibitors and their servants will not be allowed to pen or unpen their birds. 4. No bird may be removed from the show before the close of the same, save on account of illness and with the secretary's consent. 5. It will be open to anyone to lodge a protest for fraudulent practices against an exhibitor on paying £1 deposit, and such further sum as shall be necessary to defray the expenses, the deposit to be forfeited should the protest be considered frivolous by the Committee. Should the protest be sustained the deposit will be returned and the expenses paid by the Poultry Club. 6. An exhibitor who shall be disqualified for fraudulent practices shall forfeit all or any prizes or cups that may have been awarded to him or her at this show, in addition to entry fees.

HIGH-COLOURED CANARIES.

RESPECTING high-coloured Canaries "A. K. C." asks the following questions, to which we have much pleasure in replying.

1. Do canary and hempseed given occasionally to the birds destroy the effect of the cayenne pepper? If canary and hempseed be given to Canaries at the time they are moulting the birds will not attain the height of colour as when they are entirely moulted upon the cayenne diet; but if the birds have clear-

moulted, then the seed will not destroy the colour produced with cayenne.

2. To preserve the high colour of the birds is it necessary to continue the diet of cayenne and egg each time that they moult? Each time the birds moult it is necessary that the cayenne diet be adopted, or the birds will moult of a pale hue.

3. Is the plumage of the young birds any brighter for the parents having been fed on cayenne pepper? No. However much pepper the parent birds may have partaken of, it has no effect whatever upon the young unless the pepper is supplied to the old birds at the time the young are being brought up in the nests.

4. After being fed for eight weeks on cayenne pepper ought the high colour of the Canary to have fully commenced, and can it then return to its ordinary food of canary seed, groundsel, &c.? In reply to the first portion of the question, much depends upon what ages the birds are when the cayenne diet is first given. If the birds have moulted cayenne pepper will have no effect; but if they have not moulted, and you commence with the pepper at the proper age, the effect of it will be seen in less than half the time named.

We may also further remark: When commencing with the cayenne food, consisting of pepper, biscuit, and egg, do not let the ages of your birds exceed seven weeks. By the time the birds attain the ages of sixteen or seventeen weeks they should throw off the whole of their feathers except the wings and tails, which do not cast until the following year. If during the moulting period the birds are taken off the cayenne diet and supplied with seed and green food the effect of the stimulating diet will be at once checked, and the bird's plumage will become patchy in colour. During the pepper-moulting seed and green food will counteract the power of the cayenne. The more pepper birds partake of the higher they will become in colour during moulting. The purer the pepper and the higher the colour the greater the effect. More care should be exercised as regards cleanliness than when birds are moulted upon seed. With a pepper diet they not only increase the soiling of the cage bottoms and perches, but the birds become clog-footed, and their wings and tails likewise get soiled, unless the birds have free access to a shallow bath to wash and splash about in.—GEO. J. BARNESBY.

VARIETIES.

THE annual Dairy Show of the British Dairy Farmers' Association opens this day (Thursday) at the Agricultural Hall, London, and continues for four days, £1500 being offered in prizes for cows, heifers, and bulls. The entries in these classes number 232, all breeds being represented. Goats exceed the number of entries of last year. Cheese and butter classes all well filled, every known variety being on view. American Cheddars weighing more than half a ton. Poultry and Pigeons: two thousand pens, being three times the number of previous years. Butter-making and cheese-making will be carried on each day in the Show by country dairymaids. Models, plans, and drawings of dairy homesteads: eleven competitors. Dairy utensils, fittings, and vehicles in competition for prizes and medals. The general stalls are decidedly above the average. Amongst the principal exhibitors are Her Majesty the Queen, the Baroness Burdett Coutts, Lady Gwydyr, the Hon. Mrs. Baillie Hamilton, the Earl of Stamford and Warrington, the Earl of Rosslyn, Lord Chesham, the Hon. H. Brougham, the Hon. and Rev. F. Dutton; the Revs. H. R. Peel, R. Watson, and G. Gilbert; John Walters, Esq., M.P.; Jas. Colman, Esq., M.P.; Capt. Norman Hill, George Simpson, Esq.; R. Myddleton Biddulph, Esq.; Drs. Snell, Angier, and Crisp; St. John Ackers, Esq.; R. Stratton, Esq.; H. Lingwood, Esq.; J. N. Matthews, Esq.; George F. Burnell, Esq.; R. R. Fowler, Esq., &c. The Show opens at 10 A.M. and closes at 10 P.M. and is worthy of extensive patronage.

—HON. AND REV. F. G. DUTTON writes:—"Will you let me say that I have made it a condition of collecting for the £10 cup for Black Reds at Oxford that skinned birds shall be ineligible?"

—AT the late meeting of the Royal South Bucks Agricultural Association held at Datchet, the Prince Consort's silver cup of the value of 20 guineas, given by the Queen for root crops, was awarded to Mr. G. Botham, Wrexham; Mr. Ives, Langley, taking the second prize—a piece of plate of the value of 10 guineas, presented by Mr. N. G. Lambert, M.P. The members of the Society dined in the evening at the Royal Hotel, Slough.

—A WELL-ORDERED FARM, well-chosen stock, comfortable buildings, a neatly kept garden, roadway or entrance-way; gates well hung, fences well kept, shade trees, ornamental shrubbery, paint without and whitewash within—all these are worth more to a farmer in money value than a few hundred dollars carefully scraped together and jealously hoarded and loaned to needy neighbours at interest. No investment pays so well as money judiciously spent in farm improvements. Draining wet land will pay 50 to 100 per cent. on its cost every year; good stock will pay equally well; good roads will return their cost every year; a gate will save its cost in a short time; a good fence may save its whole cost in one night; a well-kept garden, a neat lawn, orchard and

shade trees, which need not cost \$100, have added ten times that amount to the value of a farm, and the comfort and self-respect gained through the outlay for these and from their possession are worth more than the cost.—(New York Times.)

QUEEN BEE LAYING UNPRODUCTIVE EGGS.

A CURIOUS phenomenon has come under our notice here, which, so far as I am aware, has not been observed before among the curiosities of apian science. A young queen hatched this summer after a swarm became the parent of a large hive full of bees, both before removal to the vicinity of Heather on the Mendips and during the stay of the hive there—a period of six weeks. About the 16th of August a bar-frame was taken out of the centre of the hive for examination, and was found to be full of brood of all ages. Early in September, three or four weeks later, no brood whatever was found in the hive, but a quantity of eggs in four or five combs. On Thursday, September 19th, the hive was again overhauled, but none of the eggs had been hatched; and finally on examination yesterday, October 1st, the same state of things was found continuing, with this difference that eggs were seen in only two of the combs. Now how is this to be accounted for? On the principle of parthenogenesis these eggs ought to have produced drones—that is, supposing the July-hatched queen to have been lost by accident and a younger queen to have been reared since the 16th of August, after the general destruction of drones throughout the apiary; but that the queen should continue to lay eggs which produce no life at all is what I consider a very unusual phenomenon. I have supposed it possible that a young queen was born in the month of August to supply the place of the July-hatched mother bee, but there is no evidence whatever of any such queen having been reared as would have existed in the shape of royal cells among the combs. Not one such, however, was seen. If there was no loss of the July queen the phenomenon is still more curious, for then we have to account for the hitherto prolific mother ceasing to rear brood while still laying quantities of eggs apparently devoid of all vitality. It must be added that continuous feeding has been going on in this hive for nearly three weeks, and the hive is very populous and as active and content (pollen-gathering too) as any other stock of bees in the apiary. This feeding was designed to supply the place of a quantity of honey of which the stock was plundered, some of which was extracted by an extemporised slinger, with a view to the return of the emptied combs.—B. & W.

ARTIFICIAL COMB FOUNDATIONS.

AFTER fifteen years' experience and manufacture of the above most useful apian appliance I can fully endorse all your excellent contributor "B. & W." says in its favour. The perfect straightness of comb it ensures is most valuable to the storifier, causing the various sections of his every colony to blend together as intimately as if they were an inseparable whole. Shortly after its introduction a keen Ayrshire apian carried here a young swarm for the Italian fertilisation of its queen. So neatly and securely had he attached his guide, after the manner described by me in "Our Letter Box" last week, that it bore the weight and heat of the bees themselves and the jolts and jars of a considerable railway journey and hand carriage several miles to and from the respective stations, arriving in the most perfect condition.—A RENFREWSHIRE BEE-KEEPER.

EXCESSIVE SWARMING.

I HAD a hive of bees (in one of Neighbour's improved cottage hives), which swarmed in June of this year. I put them into a hive, also Neighbour's, but they returned to the parent hive in the afternoon of the same day. They swarmed again next day and were put into the rejected hive, but returned to the old one in about an hour's time. Two or three days afterwards two swarms came out, one very large, the other small, containing perhaps about a quart of bees. The small one was put into a straw skep, the other into the Neighbour; both stopped this time and began work at once. The large swarm is now so heavy that I cannot lift it; the small hive is half full of comb, the bees have increased to about twice the quantity, they have taken 12 lbs. of sugar and are still storing it away. So far, all well. Now for the parent hive. After the swarms were gone I began to think of getting a little honey, so I placed a large super, covering all three holes on the top. The bees constructed three combs and filled them with honey, but bad weather coming on they could not get out much, so they carried it down below. A fortnight ago I examined it. I could not lift the hive, and of course there was nothing in the super, but I congratulated myself that I should have two good hives to super and the skep to breed from next year if I can keep it. Judge, then, my astonishment this morning, September 30th, when I found not a bee in the old hive and half the honey gone. The strong swarm which stands close to it seems heavier, and I suspect the honey is there. But where are the

bees? Why did they leave their hive full of honey?—N. T., *Cheshire*.

[The letter of your correspondent presents to view very unusual and remarkable occurrences difficult to explain. The old hive swarmed twice, the swarms returned both times after they were hived. The probability is great that the queen was too old to go with the swarm and was lost on making the second attempt. Young queens were fully ripe and ready to take her place, and, as "N. T." puts it, "two or three days afterwards two swarms came out, one very large, the other very small, perhaps only about a quart of bees. Both were hived, commenced to work at once." These swarms were headed, doubtless, by young princesses, and were virtually casts, or second and third swarms. Why the bees left the parent hive at the end of the season we cannot explain in the absence of sight.—A. P.]

INCOME OF STEWARTON HIVE, 1878.

I STARTED keeping bees the year before last, and erected a rough house to hold them. Buying them and sugar to keep them alive afterwards took a good deal out of my pocket and put nothing into it. This I felt, as I am a cottager with a numerous family to support, and living in a village near a railway station, the smoke of the engines and noise of the trains, away from heather or good keep, made me almost think I had made a mistake in going in for bees at all, so that in June I parted with one of my straw skeps, having two left. I started with three at first, which gave me neither swarms nor honey last year, and were often at death's door and had to be fed in summer, and many a thought it gave me how I could work them to most profit this year and get some money back out of them. In my difficulty I made application to a gentleman who I heard knew a good deal about bees, and who resides in our neighbourhood and writes in your Journal, "A RENFREWSHIRE BEE-KEEPER." This gentleman advised me to drive the Stewarton hive, and was so kind as to make me a present of a 9-inch body box, sheeted with wax sheet from his machines, which kept me going all summer, also good sound practical advice as to the proper management of the Stewarton system. I have also several of Mr. Allan's boxes direct from Stewarton, and wondered how he could make such strong dovetailed boxes with eight moveable bar slides, pegs, and sliding doors, all for 6s., so little more than a common straw skep. I hived my first prime swarm in a 9-inch box on the 17th of June, and lost much time watching for the other, which did not come off till late (12th July), and hived it in another 9-inch body, joining it to the first the same night without loss of bees. Gave first one honey box, then another on top of it, and last a third at the top of all to hold bees and keep them from swarming, as I had been instructed, and they wrought out in the three entrances splendidly. The lowest honey box (over 20 lbs. of honey) was a beauty, and I won the first prize with it at our flower show. My income from this hive was:—First box sold for £2s. 2s.; prize money for it, 10s.; second box shallow, sold for £1; third box, 20 lbs. sold at 1s. 6d., £1 10s. Total, £5 2s. Had I parted with my two top swarms for 20s. each, less 6s. for two skeps at 3s. each, would have brought me in 34s.; but I see now I took good advice to keep them, as they made over £5, and I have my capital hive left for next year. Hived second swarms in Stewartons as well as drawn out bees the twenty-fourth day after swarming, and was very thankful to get rid of my straw skeps, which bred no end of moths and vermin in my bee house. My wife took one of them into the nearest town, but nobody would buy it, and we had to run it. I found the gentry round about our neighbourhood willing to give 6d. per pound more for top box comb than for run honey, and mean to run as little as can be helped next year.—J. R.

OUR LETTER BOX.

CHICKENS DYING WHEN A FORTNIGHT OLD (*Two-years Subscriber*).—You have not told us whether your birds all roost in the same house or have separate houses. We expect they are together, and if so with a straw bed we should look to that for the disease. Fowls and Ducks never do well if they roost with Geese, and these latter also object to promiscuous lodging. Fowls will be healthy where they have a straw bed. It is always offensive, and it never harbours vermin let it be ever so dry; but where it is also used by Ducks it is filthy and leads to disease. In all particulars Ducks and Geese are unfit to roost with fowls, and will always cause disease. Where are the hens with their chickens in the early days of their existence? If put out under rips in the stack yard they should be the pictures of health. They do not require a shed except in winter and early spring. Do they get clean water? Is it running or stagnant? Has any part of their house a boarded floor? If it has, remove it. The gaping would seem to indicate they were suffering from that. As that disease affects only chickens we advise you to give them when attacked a pill of camphor the size of a pea, and let them have no water to drink that is not strongly impregnated with camphor. We advise you to separate a good portion of your poultry house and appropriate it to the fowls exclusively, but as we imagine you have grapes and vermin among your poultry every part of your house must be thoroughly scrubbed with a birch broom and afterwards lime-whited. The floor should be scraped till at least an inch has been taken from the surface. Every vestige of straw should be removed. The floor should be perfectly dry. Let your food be ground oats or barley meal slaked with water morning and evening; maize, barley, scraps of bread or meat at mid-day. If you can give the whole place to the fowls so much the better. Geese and Ducks will always find roosting places, even

in an open yard. We are strongly disposed to believe your Ducks and Geese die of cramp, induced by the filthy straw on which they roost. It is in consequence of their habits they are allowed to choose their lodgings. In many places the Geese roost on the water, and if left at liberty always resort there at the approach of night. Give your ducklings oat or barley meal put in a shallow vessel. The bottom of this vessel should be covered with a sod of growing grass cut to its shape. Put on this some fine gravel, then the meal. Put sufficient water to cover the whole. They will eat greedily of it, and it soon restores them. The height of the vessel must allow the ducklings to feed at it.

PARAKEET'S FEET SWOLLEN (*E. W.*).—Let the water from the swellings escape by piercing them with a stout needle. Feed the bird on fruit.

SWOLLEN CROP (*L. I. B.*).—A dessert-spoonful of gin will probably remove it.

CLEANING CANARY SEED (*M. Hamilton*).—We are not aware that there is any machine specially used for cleaning canary seed.

STEWARTON HIVE (*C. R. E.*).—"A CROYDON BEE-KEEPER" says you can obtain the hive from Mr. Holland, hive maker, Harrison Rise, Croydon, Surrey.

STEWARTON HIVE.—We are informed that we wrongly named the maker. He is Mr. James Allan, cabinetmaker, Stewarton, N.B. The price is 12s.

HOUSEHOLD BREAD (*Uae*).—To 10 lbs. of flour in a kneading-trough put a small handful of salt. Stir into this about two quarts of water, more or less, as some flour absorbs more water than others. For very white bread, made with superfine flour, the dough should be softer than for seconds or brown bread. In summer the water may be lukewarm; in winter, considerably warmer, but never hot enough to kill the yeast. After the water is mixed with the flour add a cupful of good yeast, then knead the bread, and leave it to rise in a warm place, covered with a cloth. If all goes well it will rise sufficiently in the course of an hour or an hour and a half. Then divide it into rolls, loaves, or tin-breads, as wanted, and bake. For a 3-lb. loaf take 3½ lbs. of dough; for a 4-lb. loaf 4½ lbs. 11 ozs.; for a 6-lb. loaf 6½ lbs.; and for an 8-lb. loaf, 9 lbs. of dough.—(*Cassell's Dictionary of Cookery*.)

REMARKS.

- 2nd.—Fair bright morning, cloudy afternoon, fair evening.
3rd.—Very foggy morning, cleared by 9 A.M., bright day; cloudy evening.
4th.—Foggy in early morning, afterwards fine warm day; very clear fine evening; starlight night.
5th.—Bright and fine in early morning, foggy from 7 A.M. till 10 A.M., rest of the day fine and hot; quite a summer's day.
6th.—Dull close morning, rather gusty in afternoon, still dull but occasionally a gleam of sunshine; rain from 5 P.M. till 7.30, fine afterwards.
7th.—Fine bright day, high wind, not quite so warm as last few days.
8th.—Wet in early morning, bright and sunny after 9 A.M., windy; clear bright evening.

On the whole a week of fine fresh weather, and some days very warm. All the means of thermometric readings are above those of last week. The mean of the barometer is, however, slightly lower, owing to the low readings at the end of the week.—G. J. SIMONS.

COVENT GARDEN MARKET.—OCTOBER 9.

THERE is a slight improvement in the demand for best Apples, although business is quiet, but inferior sorts hang on our market. A better supply of Pears has reached us, and prices are lower. Vegetables are plentiful.

From observations taken near London during forty-three years, the average day temperature of the week is 59.0°; and its night temperature 40.6°.

OUR STRAWBERRY BED:

INCLUDING PRACTICAL HINTS BY THE LATE HENRY DOUBLEDAY.

WITHOUT the support of such an authority as the late Henry Doubleday I should hardly have ventured to give our experience upon Strawberry rearing to the public.

About fifteen years ago we became possessed of an old walled-in garden, where Apple trees flourished and Gooseberry trees were covered with moss, a patch of Raspberry canes bore scarce and stunted fruits, and walks and plots, including a Strawberry bed, could hardly be distinguished from the wilderness around of Sow-thistles, Rushes, Groundsel, Chickweed, Nightshade, Bindweed, and a host of other weeds which met the eye on every side. To our great surprise, in spite of the weeds, we found one or two very tolerable dishes of old white Strawberries, which, though small, were exceedingly well flavoured. We had brought with us an experienced gardener, who shook his head wisely, and told us to wait till next season and he would show us what a Strawberry bed should be. So we waited. The weeds and Strawberries were dug up, barrowfuls of manure and turf were liberally applied to the plot, which was carefully tilled, and the Strawberry plants were set in neat rows about 2 feet apart. The season of blossoming came, and Patrick exulted over the quantity of white flowers; but for seven years from that time we had not a single dish of Strawberries fit to place upon our dinner-table. A scarce supply of shrivelled and wizened fruit perfectly hard at the apex rewarded all our care. Numberless plans were adopted, and runners of British Queen from a friend's garden were tried in vain, and we became thoroughly disgusted. At last C— said, "Why not write to your kind old friend Mr. Doubleday, and ask him for information?" The happy thought was adopted, and by return of post came a letter offering if we would throw out all our old Strawberries to send twelve different kinds of runners for trial in our garden, an offer which I need hardly say was thankfully accepted. With the Strawberry runners came the following directions and account of his own management:—"I grow all my Strawberries in beds with paths between them; each bed contains thirty-one plants 2 feet apart in the rows, and the rows 2 feet apart also. I have thirty beds, fifteen of which are replanted every year. The runners are potted, and as soon as they are well rooted they are planted out. I have just finished five beds (August 1st). A limestone formation is not very favourable to Strawberries, as they prefer a rich heavy loam; but I think you ought to have plenty of good fruit. From what you say I think the surface roots are injured in some way. In forming new beds some good rotten manure should be dug in, and the soil should be well broken to pieces. A week or so afterwards, if the plants are ready to put out, the lines for the rows should be marked out and the ground be trodden down till it is quite firm and solid; the plants should then be put in, and the soil pressed or trodden down till quite firm, not placing the crown of the plants too deeply

in the earth; they should then have a good soaking of water. When the surface of the bed is dry enough it should be made level with a Dutch hoe and rake, but the soil ought not to be moved more than an inch deep, the runners will then only want watering when the weather is dry. All runners which they send out should be cut off and the bed kept clean of weeds with a Dutch hoe. The ground must never be forked or dug after the plants are put in; this is a very important point. Digging between the rows, which is often done in the spring by gardeners who ought to know better, destroys all the surface roots which support the fruit, and of course, though the plants may blossom abundantly, they produce little or no fruit. A good coating of rich manure laid on the surface of the beds in March is very beneficial to the plants. They should only be left two years; in fact when properly managed they might almost be treated as annuals. When watering in dry weather I give each plant two quarts of water." Half of the Strawberry runners sent by our generous friend (*i.e.*, six of each kind) we planted when well rooted in our old Strawberry plot, giving a small bed to each variety. The others were tried in a border from which Potatoes had first been dug, merely pulverising and then rolling the ground according to Mr. Doubleday's directions, and we waited anxiously for the result. On the old bed we had a few miserable berries "wizened" as in old times. The new border produced upon each plant three or four healthy and enormous Strawberries. For another season we left both beds untouched, merely weeding by hand and giving in autumn a good surface-dressing of decayed leaves, and in spring of manure to the young plants. On the border we had a very fine and abundant crop, on the beds not a berry worth gathering; so a number of runners were rooted, a spot of ground lately occupied by Potatoes chosen, and from that time we have never wanted Strawberries either for preserving or for table use. An accident discovered the secret of the old Strawberry plot; the soil, already porous and light, had been rendered so loose by the quantity of turf which had been dug into it by our "experienced" gardener that it would not bind round the young plants, and of course would not retain sufficient moisture to swell the fruit. And from experience we have little doubt that in any limestone garden turf is poison to the ground for Strawberry plants.

Mr. Doubleday continued to take a great interest in our experiments, and from time to time we received valuable hints. With any very valuable new Strawberry he recommended plunging small pots filled with sandy soil in the bed and pegging down the earliest runners into these without removing them from the parent plant till well rooted. The top of each runner should be nipped off, as it is likely to produce a second young plant, and to weaken the first and best offset. This plan is of course impracticable in a crowded bed, and if the pots containing runners of good kinds are plunged in large boxes with soot or lime beneath them and left for three or four weeks in some shaded spot of the garden they will form excellent plants, of which the balls can be turned out without any injury to their mass of roots when the bed is ready for them.

A theory having been started by a gentleman living near Epping of fruitful and unfruitful runners, we asked Mr. Doubleday's opinion of the subject. He answered, "I give away bushels of fruit every year [he was too modest to add, "and frequently obtain prizes"], and I can only say in twenty-nine beds averaging about twenty-five plants in each there is not a barren Strawberry, nor do I believe such a thing exists, except from bad cultivation. I always plant the earliest and strongest runners, and treat my beds almost as annuals, renewing them frequently with runners." This system, of course, produces enormous fruit, but we have had fine healthy average Strawberries weighing about two dozen to the pound from beds four or five years in cultivation, finding it sufficient to plant a young strong runner in the place of an old one here and there through the bed; and *Crimson Queen*, a most capricious Strawberry, was far more productive the third year than at first. Birds and frogs were our greatest enemies: against the former Mr. Doubleday's plan of enclosing each bed with boarding 14 inches high and netting on top is an excellent guard; but in the case of our walled bed it could not be accomplished, and before the fruit was ripe we constantly found a plethoric amphibian monarch of all he surveyed guarding a heap of gathered and half-decayed Strawberries which he had evidently procured for a *bonne bouche*. I know the fact of Strawberries being devoured by frogs is doubted by many writers, but the same thing occurred in a friend's plot of ground; frogs and heaps of fruit were found by the gardener, who was at his wife's end to discover the robber, "as there was not a rat in the garden."

With regard to watering our plants our kind old friend gave us another hint. "I never give my Strawberries any water if I can possibly avoid it till the fruit is setting; then I make the gardener give each plant two quarts. Of course a dry or wet season must prove an amateur's guide in this particular—i.e., whether this watering is to be repeated; but less than two quarts at a time will not saturate the ground sufficiently to be of any real benefit to the plants."

Of the Strawberry runners sent by Mr. Doubleday we found *Royalty*, Sir Joseph Paxton, President, Cockcomb, and Amateur succeeded admirably, and Cuthill's Prince of Wales bore abundantly its beautifully coloured fruit, of which such quantities are annually used by Gunter for preserves for the Royal household. *Waltham Seedling* failed on an exposed bed, and so did *Crimson Queen* till removed to a shaded border; but except for show, from its brilliant colour and size, the latter is hardly worth growing for household purposes, as it is a decidedly shy bearer.

I must now conclude this little history of a Strawberry bed. The friend to whose never-failing kindness we were indebted for success has passed away from us; but if the amount of varied information which his correspondents received from him could be collected and arranged a volume of real practical value might be given to the public, with an assurance that whether the subjects treated of ranged from the markings on a butterfly's wing to the growth of a simple flower, they would stand the tests of deep study and truth.

[The above notes are sent to us by Mrs. Battersby.—EDS.]

CULTURE OF AQUATIC PLANTS.

I THINK the cultivation of aquatics in the flower garden is not nearly so general as their beauty and facility of growth require. I have a small oval basin about 18 feet in the largest diameter, set round with a large rockery, which has for many months past been the most attractive feature in the garden, and at the very slightest expense or cost of trouble. I note a few facts for anyone desirous of making such an addition to their garden as that which has afforded me so much pleasure.

The form and size of the basin will, of course, be determined by the space and locality. If the oval is chosen, which I think is the most effective, a good proportion for the diameter is 3 to 2, and according to taste the margin may be flat and only slightly raised above the general level, or carried up to 12 or 15 inches above the surface, so as to form a slope to back up the rockery and a site for the growth of *Sedums*, *Saxifrages*, &c. Ordinary poor cement concrete, with a thin surface coating of richer cement handfloated or trowelled off, are all that is requisite, and the cost should be inconsiderable. The depth of the basin need not exceed 3 feet, of which 9 or 10 inches may be filled-in with soil (or the latter may be confined to large pots or tubs disposed suitably on the bottom). In this the more robust plants may be planted.

A few crowns of the white and yellow Water Lily (*Nymphaea alba* and *N. lutea*) suffice in the course of a season or two to cover, if permitted, a large portion of the surface with leaves and flowers. I find the first by far the freest in flowering, and have an abundance of flowers from early in June to late in September. The *lutea* I find later in commencing and earlier in ceasing to flower. Both in shallow water vary the usual habit of growth by projecting a portion of their large leaves in handsome groups above the water.

There are many hardy aquatics both indigenous and exotic which may be introduced with good effect. The common Buckbean (*Menyanthes trifoliata*), for example, which requires only 6 or 8 inches of water, may be grown in pots or boxes supported on inverted pots. The floating stems will extend on either side, and produce bunches of white flowers at the end of May or beginning of June. The Flowering Rush (*Butomus umbellatus*). The Cape Lily (*Aponogeton distachyon*), noticeable for its profuse and long-continued bearing of bizarre white and speckled flowers. The *Villarsia Lily* (*Villarsia nymphaeoides*), beautiful either as to its small cordate variegated floating leaves, or the yellow blooms projecting conspicuously above the water surface. *Jussiaea grandiflora*, valuable as affording handsome yellow flowers late in the season and from having a very pretty habit of growth. Planted in shallow water it sends out numerous floating stems with, at frequent intervals, leaves and flower stalks; its growth is extraordinary. I have this season plants which have made 18 feet in growth from cuttings taken late last season and put out early this spring.

Handsome masses of foliage are afforded by several species of the Iris, the Water Plantain (*Alisma Plantago*), and the various Bullrushes. The common Marsh Marigold (*Caltha palustris*) plunged in pots in the early spring will yield for a few weeks beautiful groupings of foliage and handsome yellow flowers, and may then be removed to make room for other and later-flowering plants. The variety *Caltha palustris major* has larger and handsome double flowers, commencing about a month later than the preceding. Again, nothing can be more ornamental than the common Water Crowfoot (*Ranunculus aquatilis*) which decks so many of the ponds in the vicinity of London. This may be planted in small tufts, and will develop its surface leaves and great profusion of gay white and yellow blooms for several months, commencing in the early spring and lasting till May. The Frogbit again (*Hydrocharis morsus-ranae*) is an interesting plant, with free floating G-like leaves, extending by runners sending down filamentous roots. The small white flowers are produced for a month or two above the surface. The *Calla aethiopica* succeeds in a small depth of water; other *Nymphaeas*, such as the charming *N. odorata minor*, and many other plants procurable from several of our florists may be employed in the basin. Where stove or even greenhouse accommodation is possessed for shelter during winter a beautiful variation may be secured by putting out in the summer months the strange-looking floating *Pontederia crassipes* and the *Limncharis Humboldtii*, graced with a lovely *Convolvulus*-like large primrose-coloured bloom.

If a plentiful water supply is obtainable and the pond is intended to subserve watering purposes, its abundant and frequent addition will insure cleanliness. If otherwise, the principle familiar to the possession of aquariums may be adopted, and no more added than is requisite to supply the loss from evaporation. In this case, after having become clouded for a time by minute coniferoid vegetation, will clear itself and remain so, this desideratum being hastened by the introduction of such fast-growing plants as *Myriophyllum spicatum*, *Anacharis Alsinastrum*, *Ceratophyllum demersum*, &c., which rapidly oxygenate the water and also leave a supplemented groundwork to the more conspicuous form. These can readily be removed from time to time when too abundant.

There are some plants, such as the Water Soldier (*Stratiotes aloides*), which have great effect, with, however, the objection that they are liable to emit secretions. If only a few water snails exist in the pond (and these latter are sure to be introduced sooner or later), a few bright-coloured gold fish and Crimean carp form appropriate and ornamental additions. Central fountains are to my mind eyesores, unless provision is made for their continuous supply. —J. PITHERS.

FORCING VEGETABLES.

FRENCH BEANS.

FRENCH BEANS are from eight to ten weeks forming pods after the seed has been sown, therefore those who wish to have

a supply of this esteemed vegetable about Christmas should lose no time in sowing the seed. The French Bean is one of the easiest vegetables to force provided it is always kept growing, but in the winter season it must not be subjected to any kind of check, because once its growth stops it never does so well afterwards. It is in temperature and watering that checks are most liable to occur, and those with no perfectly heated forcing places should take care that they do not begin at this season with a higher temperature than they can afterwards maintain. It is always safest to begin with a low temperature and increase it afterwards. Any French Beans sown for producing before the new year are all started into growth in a cold frame, and by being kept a little close now and near the glass they grow strong and sturdy, and they go on rapidly when they are placed in a little heat. Now and always we start them into growth in 3-inch pots, placing eight or ten beans in each pot, and using a light rich mixture of loam and old Mushroom dung. One hundred pots give many dishes, and this quantity put in every three weeks will keep up a good supply, but for affording a smaller supply four dozen pots will be found very useful. Every person who has suitable accommodation should grow a few pots of French Beans, as two or three pots can be placed in one corner and two or three in another, and in this way the space they take up is hardly ever missed. We force ours chiefly on shelves in the Pine stove and in the beds of Melon and Cucumber pits, and all of these places answer the purpose very well.

As soon as the plants begin to look crowded in the small pots they are transferred to 8-inch pots. A few crocks are placed at the bottom of each, and a little rough manure and turf is placed over them, and the plants are then shifted without breaking the ball of roots. Light rich soil is again used in potting, and little water is given until the roots take hold of the new soil; after that they are never allowed to suffer by want of water, and on all fine days they are lightly syringed to prevent red spider doing injury. This is the only insect that troubles them. They should not be syringed much when in flower, and at that time liquid manure should be given them. The pods should never be allowed to become old on the plants, especially at first, or they will not continue bearing for any length of time.

In the month of November and after that we do not start them into growth in a cold frame, but in a house very slightly heated, always taking care not to give them a "quick start" in a high temperature. They will start freely into growth in a heat of 50°, and they will grow to maturity in an average of 60° or 65°. When French Beans are placed in early vineries great care is necessary to prevent red spider from gaining a footing on them, as it will quickly reach the Vines and may do much harm to them. The Beans may be started into growth in an early vinery in spring, but we do not like to trust them there to make their growth. Osborn's Forcing and Fulmer's Forcing are both good varieties, and may be depended on for giving a supply at all seasons.—A KITCHEN GARDENER.

THE ROSE ELECTION.—No. 4.

MANY thanks to "D., Deal," for his kind acknowledgment of the election labours. It is unnecessary to allow that there is a large amount of work in it, but perhaps without it or something similar I should be often like Pickwick's fat boy, "in the arms of Porpus;" the thorns of the Roses, I suppose, help to keep me awake. I cannot now say on whose authority I gave the credit of Lord Macaulay to Mr. Ward; it was so stated last year and passed without challenge. Souvenir d'Elise was also last year given to Marest; the latter I find given to Marest in Ellwanger & Barry's catalogue, the only catalogue that attempts to give the raisers of the older varieties. If "D., Deal," can prove that these two raisers' names are incorrectly given now would be the time to make a note of it.

To "A LOVER OF ROSE SHOWS" in reference to duplicate Roses, he may judge for himself by consulting the poll, in which the votes given to each of these Roses separately mark the estimation in which each is held. As I make it out, Ferdinand de Lesseps is far and away considered the best of that set; Eugénie Verdier, Baron de Bonstetten, and Alba Rosea of theirs; so that were I asked to give an opinion I should give the general opinion as evidenced by these votes. In the case of Eugénie Verdier I might qualify it by stating that I personally consider Marie Finger the more robust.

Lastly, to "ONE OF THE MILLION" I may say that the general exhibition varieties being fairly set at rest for a year

or two by the present election—though of course it will not agree with the opinion of any separate elector—I propose, with the consent of our Editors, to have next year a smaller election of the best exhibition varieties of recent introduction, and also one of garden varieties. This I fancy will enlist our friend Rev. W. F. Radclyffe's sympathies, and I venture to predict that not a few in the forty-eight will obtain honourable mention even for their garden qualities. By-the-by, has our friend tried Marie Baumann on the seedling Briar? If so, I hope he has changed his opinion about this brilliant jewel of the Rose tribe.—JOSEPH HINTON, *Warminster.*

IN the following closing returns of forty-eight varieties the Roses are placed as the first best twelve, second best twelve, and next best twenty-four exhibition varieties.

Mr. JOHN FRENCH, *Gardener to Rev. J. P. Tomlinson, Rooklands Devon.*

ACHILLEA UMBELLATA.

THIS plant, which was sent out I believe by Messrs. Backhouse & Son of York a few years ago, is one of the best of the white-leaved section of carpet-bedding plants that I know. I was surprised not to see it more in vogue in the London parks, as it has higher qualities to recommend it than have many plants that I saw grown there. It is perfectly hardy, but it answers best to strike a batch of cuttings every year, either in the autumn or in the spring. I like spring-struck cuttings best, unless it is wanted to raise a large stock in a short time. I take the old plants up and place them in boxes as thick as they will stand without overcrowding, and stored in a cold house or frame. These supply a large quantity of cuttings in February or March, which will strike freely in any shady place where the temperature does not fall much lower than 45°. The cuttings are inserted in pans or boxes about 1½ inch apart, where they remain till bedding-out time. They should be planted not wider than 3 or 4 inches apart, as they are not

rampant growers, but soon form tufts of beautiful white deeply serrated, or rather pinnated leaves. They never rise above 2 inches high, and the growth is so compact that the surface is always perfectly level, without so much clipping, pinching and training, so necessary with many other plants used for carpet bedding. The colour, compact habit, and above all its strikingly pretty leaves as well as its hardiness and easiness of cultivation, ought to make this plant one of the greatest favourites in future for the style known as carpet bedding.—R. M'INTOSH.

TEBBS' UNIVERSAL STOVE.

SOME time ago Mr. Tebbs invented, and first submitted to the gardening world through these columns, his universal fumigator, a simple and useful garden appliance which has met with a very large share of patronage both by gardeners and amateurs. Encouraged by the success of that article, and recognising the want of a portable, cleanly, safe, and effectual apparatus for excluding frost from the small greenhouses of amateurs, the inventor directed his attention to that object; the result is the "Universal Stove" now submitted to the public.

Fig. 45.—Tebbs' Universal Stove—Elevation.

This stove differs from all others that we have seen that are heated by gas or paraffin, inasmuch as it is not a gas or paraffin stove merely but a hot-water apparatus; and it again differs from the orthodox mode of heating by hot water, because the heat is given off from the inside instead of the outside of the pipes.

"In introducing to the notice of the public this new heating apparatus, my main object," says Mr. Tebbs, "has been to place in the hands of all interested in the cultivation of plants under glass an original, safe, and economical means by which the greatest amount of heat can be obtained with the smallest amount of fuel; the stove requiring little or no attention for twenty-four hours, and giving off nothing but pure heated air. This is obtained by bringing the pipes or tubes together in one body, and allowing the smallest space between them for the circulation of hot water on their outer circumference, retaining the inner circumference for the heating of the atmosphere as it ascends by the natural attraction of the vertical heated tubes or pipes."

As will be seen by the accompanying figures the stove is simply a bundle of pipes vertically arranged and open at both ends, every pipe being surrounded by water, the whole being enclosed in a cylinder. On the water being heated the heat is of course distributed from the inner surfaces of the pipes—is, in fact, heated air, the cold air constantly rushing in at the bottom of the pipes and passing out at the top in a heated state through a perforated lid. This lid is moveable. The stove which we inspected at work was heated by a paraffin lamp, and on removing the lid we can

testify that the heated air was perfectly sweet. The circulation of the water is secured by a pipe arranged at the back of the stove at the outside, the top being the "feed," seen in the engraving (fig. 46), the bottom entering the stove at its lowest point.

The "feed," or reservoir, is also by a simple contrivance made to act as a condenser. A pipe passes through the bottom of it, its upper orifice being close to the inner side of the lid. Through this pipe a cool current of air passes, keeping the lid comparatively cool and condensing the steam which rises from the hot water. The pipe named also acts as an overflow when the water rises to the top of it, as it occasionally may do when the water is boiling. By this arrangement the waste of water is minimised and the boiler only needs replenishing once in twenty-four hours, and then only by adding less than half a pint when the stove has been highly heated during the whole time.

Very simple and efficient is the arrangement at the bottom of the apparatus for dressing the wick and replenishing the oil. In ordinary paraffin stoves the cylinder has to be raised for that purpose, but in the "Universal" that is not necessary. A slide is raised and the vessel is drawn forward after the manner of drawing out an ashpan, and the work is done with

Fig. 46.—Tebbs' Universal Stove—Section.

the greatest ease. The vessel containing the oil is also kept cool, therefore perfectly safe, by being surrounded by a collar that is in contact with the lower part of the stove where the cold air passes, and where also the water is necessarily in the coolest state.

The heat is, of course, quite under command by simply turning on or diminishing the flame as required; but on this point a word of caution may be given, for although the lamp may be turned down to its lowest burning point it should never be so low that the flame is below the shield of the burner; for, as pointed out by Mr. Tebbs, unless the flame is in contact with the air the gas evolved from the oil is not consumed and an unpleasant smell is produced.

A "false top" can be fitted to the stove to hold water, so that vapour in proportion to the heat of the stove can pass into the house as required. This also we saw in operation.

The stove is made of block tin, and is neat in appearance and durable. We consider it worthy of trial, and draw attention to it as the most promising stove of the kind that has come under our notice.

ROSES.

I HAVE unwittingly omitted the name of the best all-round H.P., Jules Margottin from my list on page 276. I will not withdraw any of those named, but trust "Jewels" may be considered one of the forty which are not thieves. I have always been of the opinion that the election should not be confined to exhibition Roses, but that the list should be of Roses for exhibition and ornament. The best suggestion rela-

tive to Roses that I have seen for some time is by "ONE OF THE MILLION," page 280. 1, The freest bloomers; 2, the hardest; 3, the best for bouquets. I beg to add 4, the best for scent; 5, the best in bud for button holes. Expanded Roses are not good for button holes. The opening buds of the following are very good—Solfaterre, Triomphe de Rennes, Madame Knorr, Jules Margottin, Marguerite de St. Amand, Edward Morren, Rêve d'Or, Céline Forestier, and I suppose the Teas generally before expansion are good for the purpose. I doubt if Devonensis and Souvenir d'Elise have yet been excelled. Teas should be shown by themselves; Tea-Noisettes may be shown with the Hybrid Perpetuals.—W. F. RADCLIFFE.

ROYAL HORTICULTURAL SOCIETY.

OCTOBER 15TH.

SELDOM have we seen the Council Room so variedly and artistically furnished with rare, beautiful, and valuable plants, collections of cut flowers, and contributions of superior fruit, as it was on this occasion. Charming groups of Orchids and ornamental-foliaged plants were arranged by Messrs. Veitch, Williams, Bull, and Osborn; a fine assortment of Tuberous Begonias by Messrs. J. Laing & Co.; a grand collection of hardy flowers by Mr. R. Parker, Tooting; remarkably beautiful boxes of Roses by Messrs. William Paul and Son; various cut flowers by Mr. Cannell; excellent groups of plants from Chiswick, and a wonderful collection of hardy plants by Messrs. Veitch suitable for outdoor decoration during winter. It was in fact one of the best meetings of the season, the whole of the room and entrance being filled with objects of great horticultural interest.

FRUIT COMMITTEE.—Henry Webb, Esq., V.P., in the chair. Mr. Goodacre, gardener at Elvaston Castle, Derby, sent six handsome bunches of Lady Downe's Grape, which were awarded a cultural commendation. Mr. Harrison Weir, Weirleigh, Kent, sent bunches of Muscat Champion splendidly grown, and though not quite ripe were awarded a cultural commendation, of Venn's Muscat two large bunches, and of his seedling "The Artist," which is so much like the Black Hamburg that the Committee requested to see it again. Messrs. Lane & Son of Berkhamstead exhibited a magnificent collection of twelve varieties of Grapes, three bunches of each; the Muscats of Alexandria and Gros Colman were especially notable, and a gold medal was unanimously awarded by the Council. A number of varieties of Grapes were sent from the garden at Chiswick. Madresfield Court was in very good condition and good flavour, Mrs. Pince was also fine, and Dr. Hogg, which had become much shrivelled, was also rich in flavour. Golden Queen was inferior in flavour, and a constitutional defect was observed in the veins of the flesh which appeared to produce a sort of rot. A cultural commendation was awarded. G. F. Wilson, Esq., of Heatherbank, Weybridge, sent very fine fruit of Doyenné du Comice Pear, beautiful in colour and delicious in flavour. The fruit was set in an orchard house and ripened out of doors. A cultural commendation was awarded. Messrs. W. Paul & Son exhibited fruit of two Pears, one called Vingt Mars and the other Duc d'Alençon, neither of which possessed any great merit. Messrs. Rivers & Son of Sawbridgeworth sent fruit of three Plums, all of which are remarkable for their lateness. They were Bonnet d'Evêque, Wyedale, and Autumn Compôte. They also sent a seedling Pear from Beurré de Capiaumont, and one from Léon Leclerc de Laval, neither of which had much merit. A seedling Bergamot had greater merit. The following Apples were also exhibited: American Mother, Washington, Pine Golden Pippin, Scarlet Golden Pippin, and Bijou. A letter of thanks was awarded for the collection. Miss Emily L. Lowther Thornton, Ryde, sent a seedling Apple, which was recognised as Hollandbury. Mr. John Redshaw, Bourne, Lincolnshire, sent two seedling Apples, neither of which possessed much merit. The fruit of a very handsome and fine Apple called Baumann's Red Winter Pearman was received from the garden at Chiswick. It is like a highly-coloured Blenheim Pippin with some russet upon it, and was awarded a first-class certificate. A very excellent Melon called Exquisite was shown by Mr. C. Tyler, The Gardens, Hassobury, Bishop Stortford, but it was rather over-ripe. Mr. W. Johnson, The Gardens, Bayham Abbey, Kent, sent a seedling Melon called Bayham Hybrid, which was inferior in flavour.

Mr. Alexander Maule of Bristol sent some fine specimens of fruit of *Pyrus Maulei*, and a pot of marmalade made from the fruit. Mr. Miles of Wycombe Abbey Gardens sent five fine specimens of Lord Carington Pine Apple, to which a first-class certificate was awarded last year, and now a silver medal was awarded for the present exhibition. It is a distinct and handsome Pine and esteemed for its good keeping properties. Mr. Sage, The Gardens, Ashridge Park, Berkhamstead, sent a specimen of Black Hamburg Vine in a pot most artistically trained and bearing eleven excellent bunches. It was awarded a silver medal. Mr. Peter McKinlay, Beckenham, sent a dish of Woodstock Kidney Potato, a handsome kidney, very smooth, and with few eyes. It was awarded a first-class certificate.

Mr. G. Goldsmith, gardener to P. Hardwicke, Esq., Hollenden, Tonbridge, sent a good collection of Pears, which was awarded a silver medal. Some very interesting collections were exhibited by the following nurserymen:—Messrs. Veitch & Sons, ninety-nine varieties of Apples grown in their Fulham Nursery on the French Paradise stock; Messrs. William Paul & Son, 150 varieties; Messrs. Paul & Son, Cheshunt, sixty varieties of Apples and thirty of Pears; Messrs. Lane & Son, Berkhamstead, fifty varieties of Apples; and from the Society's Garden one hundred varieties of Pears. To all of these a letter of thanks was awarded. Mr. R. Dean of Ealing exhibited thirty-six varieties of Potatoes, to which a letter of thanks was awarded. Mr. Allan, The Gardens, Gunton Park, Norwich, sent a large basketful of the Brown Dutch Cabbage Lettuce.

MR. PEARSON'S PRIZES FOR GRAPES.—The prizes offered for the single bunches of Golden Queen and Mrs. Pearson Grapes were awarded at this meeting. In the class for Golden Queen eight bunches were staged; Mr. Atkins, gardener to Col. Loyd Lindsay, Lockinge, Berks, winning the first position with a bunch about 14 inches long, tapering, full, berries fine, regular in size, and clear; Mr. Henderson, gardener to J. Deacon, Esq., Mableton Park, Tonbridge, was awarded the second prize for very good bunches and remarkably fine berries; Mr. Anderson, gardener to R. Clifton, Esq., Clifton, Notts, being third. Mr. Iggulden, The Gardens, Orsett Hall, exhibited the ripest and best-coloured bunch, cut from a Vine grown in a pot. It was well finished but not large.

Only three bunches of Mrs. Pearson were staged. The first prize went to Mr. Allan, gardener to Lord Suffield, Gunton Park, for a compact bunch weighing about 1 lb. with good, clear, well-finished berries. Mr. Taylor, gardener to J. McIntosh, Esq., Duneevan, Oatlands Park, Weybridge, was second with a much larger and full bunch, but berries not quite clear; and Mr. Goodacre, Elvaston Castle, third, with a bunch still larger and not well finished.

FLORAL COMMITTEE.—Dr. Denny in the chair. Commencing at the end of the room, and noting the collections in the order of their arrangement, we find first a splendidly grown plant of *Vanda cœrulea* grown by Mr. Smith, gardener to C. Lane, Esq., Badgemore, Henley-on-Thames. The plant had five spikes and eighty-seven fine flowers. Medals having been previously awarded for this fine specimen, a special letter of thanks was directed to be sent to Mr. Smith. Across the end of the room were arranged Mr. W. Paul's six splendid boxes of cut Roses; amongst the varieties were Safrano, Madame Berard, Marie Van Houtte, Souvenir de Malmaison, Niphetos, all shown in the full charm of their beauty and in large quantities, and nearly fifty others were in lesser numbers but in almost equal beauty, amongst them *Isabella Sprunt* was especially lovely, it is one of the finest of Roses for button holes. A silver Flora medal was recommended to be given for this beautiful collection. We next come to Messrs. Veitch's group, small but chaste, and containing plants of great rarity and beauty. The striking plant was *Phalenopsis violacea*, which is noticed in another column, and to which a botanical certificate was awarded. The equally rare and curious miniature *P. Esmeralda* with purplish rose flowers and purple lip was exhibited, also a new *Cattleya*—*Mastersiana*, a seedling raised at Chelsea. It has very fine pale magenta sepals, orange throat, and violet-crimson lip; *Cypripedium albo-purpureum* was also included; *Dendrobium bigibbum*, and *D. bigibbum superbum*; a fine pan of *Begonia Queen of Whites*, *Anthurium Schotzerianum superbum*, a very fine pure white spathe; and *Lastrea aristata variegata*, a beautiful and free-growing Fern, the base of the glossy green pinnæ being creamy white. For the two plants last mentioned first-class certificates were awarded.

Mr. B. S. Williams arranged a charming collection, many of the plants included being noticed in another column; but not the two fine *Crotons Prince of Wales* and *Burtonii*, nor the compact and brilliant *Croton Mrs. Bause*, nor a charming white variety of *Dendrobium bigibbum*. The *Pleione*s in this collection were very brilliant. A large gold medal was awarded for the collection.

Mr. Bull arranged a large and very fine group. Noticeable were several plants of *Sarracenia Drummondii* in small pots, well adapted for decorative purposes; a fine spike of the valuable conservatory climber *Bomarea Carderi*, to which a first-class certificate was awarded; a large plant of *Lastrea aristata variegata*, which received a similar award; the curious velvety crimson *Masdevallia velifera*, which was awarded a botanical commendation; a bright group of *Oncidium varicosum*, and in fine contrast *Dendrobium bigibbum*; a new *Bollea*, very remarkable; *Odontoglossum vexillarium roseum* very beautiful, also *D. Roezlii*; *Lilium neilgherrense*, *Lapagerias*, *Dracæna Goldieana*, *Crotons*, and *Palms*; also *Aspidium cernitum*, a very striking Fern, stately and robust, for which a first-class certificate was awarded, and a silver-gilt Banksian medal was recommended for the collection.

Messrs. Osborn & Sons, Fulham, arranged a group of hardy decorative plants and Palms. The plants of *Skimmia japonica* in this collection were profusely covered with berries. A silver Banksian medal was recommended. Messrs. Hooper & Co., Covent

Garden, exhibited a collection of *Nægeliæ*, but the plants had been spoiled in transit. A vote of thanks was awarded. Mr. Cannell exhibited a highly coloured sport of *Iresine Herbstii*, autumn-flowering *Chrysanthemums*, and beautiful single *Dahlias*. Mr. T. Moore also exhibited a collection of single *Dahlias* from the Chelsea Botanic Garden, showing how effective these old and almost forgotten flowers are for vase decoration, and received a vote of thanks. Mr. Rawlings exhibited Show *Dahlias Clara*, a splendid flower previously certificated, George Smith, and Baroness Burdett Courts.

We now come to Mr. R. Parker's wonderful collection of cut flowers of hardy border plants, which nobly held their own even when in contrast with the splendid groups above noticed. The back row from Tooting consisted of a central mass of *Helianthus oxygalis* with single yellow flowers, flanked by white and rose plumes of *Pampas Grass* and a great variety of *Asters* (*Michaelmas Daisies*); the finest of these were *Nova-anglæa*, *Amellus*, *lævis*, and *spectabilis*. Very striking were *Rudbeckias purpurea*, submontana, and *Newmanni*; as also were *Gaillardia hybrida* *Telemaquei*, *Pyrethrum uliginosum*, *Stokesia cyanea*, *Coreopsis lanceolata*, *Helianthus multiflorus majus*, *Tritoma grandis*, *Chrysanthemum lacustre*, &c. *Phloxes* were fine, also *Pompon Dahlias* in many varieties, and *Hyacinthus candicans*. A silver Flora medal was awarded.

The *Begonias* from Messrs. J. Laing & Co. were remarkable for their dwarf habit and finely formed flowers in various colours—a collection of great merit, for which a vote of thanks was awarded. Mr. H. Boller was awarded a first-class certificate for *Mammillaria sphacelata*, a dwarf-growing species with silvery spines. Mr. Green, gardener to Sir G. Macleay, exhibited cut sprays of *Dichorisandra thyrsiflora*, intense violet; *Aster Drummondii*, *Helianthus oxygalis*, and *Pyrethrum uliginosum*. A vote of thanks was awarded. Mr. Green was also awarded a first-class certificate for a grand spray of *Bomarea Carderi* containing forty-eight flowers.

From Mr. Davis, Ogles Grove Nursery, Hillingsborough, came an attractive collection of *Pernettyas* in variety. To one of these, *P. mucronata lilacina*, a first-class certificate was awarded. The berries were in dense clusters and silvery-lilac in colour, highly distinct. The varieties *Rosea purpurea* and *Rubra purpurea* were also very attractive.

There yet remains to be noticed the extraordinary collection of plants suitable for winter outdoor decoration exhibited by Messrs. Veitch. We are unable at present to enumerate the varieties, but an idea may be formed of the extent of the collection when it is stated that the plants were artistically arranged in upwards of a hundred flat baskets, each about 4 feet in diameter, and which completely filled the central portion of the entrance vestibule. They included miniature variegated foliaged shrubs, berry-bearing shrubs, flowering shrubs, Heaths, Japanese plants, and small Conifers in varied tints in extensive variety. It was quite the most complete exhibition of its kind that has ever been seen, and the Committee marked their high approval of it by recommending that the largest gold medal at the disposal of the Council be awarded to Messrs. Veitch.

From Chiswick came admirably grown plants of the valuable winter-flowering *Begonia Moonlight*; equally well grown *Mignonette*, the variety being named *Hensley's Giant*, and for which a cultural commendation was worthily awarded; the elegant *Nerine crispata*, the dwarf and dense-growing *Begonia prismatocarpa*, and well grown plants of *B. metallica*, very ornamental; also a collection of double *Pelargoniums*.

This was no doubt the finest October meeting that has yet been seen at South Kensington, and it was largely attended by horticulturists.

NOTES AND GLEANINGS.

We are authorised to announce that next spring the splendid collection of plants now at DANGSTEIN will be sold by auction by order of Lady Dorothy Nevill. An opportunity rarely occurs of a collection of specimen plants of such value being offered for sale.

— A VALUABLE and very rare Orchid has recently expanded in Messrs. Veitch's great collection at Chelsea—namely, *PHALENOPSIS VIOLACEA*. This is the first time this Orchid has flowered in any English nursery, and about the third time it has been seen flowering in Europe. It is most distinct and very beautiful. The petals and sepals are a little more than an inch long, stout, wax-like, and rather pointed. In colour they are fleshy white, tinted and tipped with buff, the base of each being of an intense purplish violet; the limb pale violet, and the labellum magenta-purple, with orange side laciniae. The leaves are large, stout, and of a clear glossy green. It is a very distinct species of a grand genus of plants. *P. Esmeralda* was also just on the eve of expansion at the time of our visit. Amongst other Orchids in flower we noticed grand examples of the Bornean variety of *P. grandiflora* with flowers exceeding 4 inches in diameter; *Oncidium varicosum*

and *Forbesii*, very fine; *Pleiones maculata* and *lagenaria*; *Dendrobium bigibbum* in variety, and *formosum giganteum*; *Laelias elegans*, very chaste, and *præstans*; *Cattleya exoniensis*; *Cœlogyne Cummingii*, richly scented; *Ionopsis paniculata*, a charming miniature; the valuable *Calanthe Veitchii*; *Aërides suavisimum*; *Miltonia Morelliana*; *Odontoglossum vexillarium*; *Vandas cœrulea*, *tricolor*, and *suavis*; several *Cypripediums*; a new *Stanhopea* from Costa Rica, and a new seedling *Cattleya Mastersiana* with fine mauve sepals, yellow throat, and violet lip. The extraordinary collection of Orchids not in flower are remarkable for their health, cleanliness, and generally excellent condition. They reflect honour on the nursery and credit on the growers who attend to them so well.

— THE beautiful Fern *MICROLEPIA HIRTA CRISTATA* exhibited last year by Mr. Williams and certificated is likely to become highly popular, as the plant increases in beauty as it increases in size. In growth it is very free, in habit graceful and elegant, in colour pleasing—a soft refreshing green peculiar to itself. As a basket Fern it is highly suitable, and for culture in pots one of the most free and useful for decorative purposes. The stock of this Fern at Holloway is very fine, and is admired by all visitors. A plant or plants should be grown by all who have at command a moderate but genial stove temperature. In the same nursery *Adiantum princeps* is very fine, and the new *A. neo-guineense* by its free growth is likely to become a valuable decorative and market plant. *Gleichenias* are remarkable by their numbers and condition, and in fine contrast are the fresh green "Filmies."

— THE new and distinct *BEGONIA QUEEN OF WHITES* is found to possess qualities that will render it especially valuable. In Messrs. Veitch's nursery plants of it closely planted in a cold frame yield beautiful white flowers profusely and continuously, which are in great demand for bridal bouquets. For furnishing vases, &c., flowers of this *Begonia* cannot fail being highly acceptable; they are pure white, not drooping, and grown as above indicated they are very large and beautiful.

— IN the Orchid house in Mr. B. S. WILLIAMS'S NURSERY AT HOLLOWAY is to be seen an arrangement of plants and flowers singularly bright yet chaste, and altogether charming. In a groundwork composed of *Lycopodium denticulatum* and *Isolepis gracilis* nestle rich masses of the brilliant Indian *Crocuses*, *Pleiones lagenaria*, *maculata*, and *Wallisii*, backed and flanked with such Orchids as *Oncidium tigrinum splendens*, *varicosum*, *Rogersi*, and a fine variety of *O. crispum*. Suspended from the roof, forming a fine canopy to the arrangement, are several plants of *Dendrobium formosum giganteum* covered with fine flowers, the group being altogether beautiful. On the side stages are flowering *Dendrobium superbiens*, which continues in flower for three months; *D. bigibbum*, *Lælia Dayana*, *Odontoglossum Rossii majus*, *Dendrochilum filiforme*, very bright; *Saccolabium majus*, and *Cymbidium Mastersii superbum*. The Orchids not in flower in this nursery are remarkable for their great numbers, robust health, and cleanliness, and powerfully impress the visitor with the importance of the trade of these aristocratic and growingly popular plants.

— RELIABLE correspondents inform us that *EUCALYPTUS GLOBULUS* flourishes not only in the Scilly Islands, but in some parts of Cornwall, near the Great Orme's Head, Llandudno, and Leamington on the banks of the Leam, and at Barns Elms near London.

— THE new hybrid *CYPRIPEDIUM ALBO-PURPUREUM* is now flowering again in Messrs. Veitch's nursery. It is the result of a cross between *C. Schlimii* and *C. Dominiana*. The flower is large and full, deep rose or rosy purple in colour, with a white-spotted throat; the tails are 4 inches in length and twisted. The plant is free in habit, almost robust; the leaves being long, bright glossy green, and gracefully arched. We shall be surprised if this, like *C. Sedeni*, does not prove an acquisition for decorative purposes.

— A NEW variety of *OUIVRANDRA* has been introduced by Dr. Hildebrandt into the botanical gardens at Berlin from Tropical Africa. The plant bears violet flowers on forked umbels, and is just about opening its blooms in its new home.

— WHILE on a visit to the gardens of Potterhanworth Rectory, near Lincoln, a fine specimen of *WELLINGTONIA GIGANTEA* standing on the lawn was pointed out to me. This tree was brought to the rectory in a small pot eighteen years ago by the present Rector, the Rev. Canon White, and is now a splendid specimen 35 feet high and 46 feet in circumference.

at 4 feet from the ground. I was also shown a plant of Maréchal Niel Rose which was planted inside the orchard house last March, and which has since made an aggregate growth of 65 feet. Some fine blooms are anticipated from this plant by the Rector and his able gardener Mr. Graham.—W. W.

BOUQUET DAHLIAS.

YOUR correspondent, Mr. William Taylor, in his article on "Mixed Borders for Autumn," page 253, asks to be supplied with a list of half a dozen liliputian or bouquet Dahlias. Having grown a few of these varieties for several years, I can confidently recommend the following as well worthy of cultivation:—

Guiding Star.—Pure white, quilled; very fine. 3 feet.

Northern Light.—Bright scarlet; dwarf and free.

Red Gauntlet.—Deep red; fine. 3 feet.

Pure Love.—Lilac rose; very fine. 2½ feet.

Little Dear.—Blush-white, flushed and tipped with rose; exquisite. 3 feet.

Little Dorrit.—Rosy lilac. 3 feet.—JOHN HENSHAW, *Harpenden, St. Albans*.

REGENT'S PARK.

It is unnecessary to enter into detail respecting the general features of this noble park, for they have been frequently referred to. We may, however, add that Mr. William Browne, the able Superintendent, who did so much to improve the flower gardening at Hampton Court, and which is now so well sustained by his successor Mr. Graham, has been especially successful in his floral arrangements in Regent's Park. A few years ago we scarcely looked for flower gardening in the park under notice beyond such as might be found in any ordinary garden in the country, but now the carpet beds are on an equal with those in the other London parks, and the great improvements lately made are highly appreciated by the thousands of visitors who crowd around the flower beds.

Fig. 47.

| 1, Base of vase. | 5, <i>Mentha Pulegium gibraltaria</i> . |
| 2, <i>Coleus Verschaffeltii</i> . | 6, <i>Echeveria secunda glauca</i> . |
| 3, <i>Alternanthera paronychioides</i> [major]. | 7, <i>Mesembryanthemum cordifolium</i> |
| 4, <i>Sedum glaucum</i> . | variegatum. |

The carpet beds are somewhat intricate in outline, but all the colours have come out most beautifully, and every plant has filled its allotted space. The colours are well and evenly balanced, all the divisional lines are neatly defined, and the selection of plants is such as to at once impress the visitor with the fact that the whole work has been done by the hand of a master in the art of floral decoration. The carpet beds are all in duplicate—that is to say, beds of the same design are arranged opposite each other on both sides of the walk. Designs of two of the beds are submitted, showing the elegance of the patterns and the effective mode of planting the beds.

Subtropical bedding is also effectively carried out, and is highly appreciated. The plants have grown with great luxuriance, and this style of garden embellishment is considerably heightened in its effects by the rich and varied scenery that

surrounds it. The following are a few examples of planting the beds: Bed No. 1.—*Ricinus Gibsoni* carpeted with *Cineraria acanthifolia*, next a band of *Pelargonium Prince Arthur* edged with *Lobelia White Swan*. Bed 2.—Centre plant of *Dracæna indivisa*, surrounded with *Abutilon Thomsoni* variegata and *Iresine acuminata* mixed; next a band of *Pelargonium Bright Star* edged with *Alternanthera magnifica*. Bed 3.—Centre *Ricinus macrocarpa*, with a band of *Pelargonium Lucius*; then a band of *Iresine Lindenii* surrounded by a mass of *Mesembryanthemum cordifolium* variegatum, edged with *Echeveria secunda glauca*. Bed 4.—Centre *Hibiscus rosea sinensis* and *Sonchus laciniatus* mixed, carpeted with *Coleus* and *Begonias*; then a band of *Pelargonium Neatness* edged with *Lobelia pumila magnifica*, and margined with *Echeveria secunda glauca*. We might mention many others, but the above will give an idea of what is being done in Regent's Park, and what may be further expected in years to come. Mr. Browne is to be complimented on the improvements that he has effected since he took the charge of the park, for waste places are clothed with Ferns and other luxuriant verdure; in fact, the park has throughout the summer been extremely and variedly beautiful.—VISITOR.

RABY CASTLE.—No. 2.

THE arrangement of the glass at Raby is very scattered, no order or method being adopted. We arrive at the second and third Peach houses, 118 feet long and 12 wide. The second house contains Barrington and Royal George, the third being entirely devoted to Admirable. The trees were in perfect health and bear heavy crops of excellent fruit. In front of these houses near to the edge of the walk is quite a hedge of *Tritoma Uvaria*, which had a very imposing appearance at the time of our visit; in front of the *Tritoma* were Stocks, *Heliotropes*, &c. Near here was more subtropical bedding. The Scotch Thistle shone with graceful effect, its silvery appearance contrasting well with its metallic and sombre neighbours. We next pass the Box garden, a geometrical design by Mr. Westcott. Adjoining is a magnificent hedge of *Fuchsia Riccartoni* 5 feet across. There is also a ribbon flower border skirting this part of the kitchen garden, in which Duchess of Edinburgh *Viola* was very fine. We next pass to the south

border, where a fine view of the Castle is obtained. This border being winding Mr. Westcott has it tastefully bedded-out with flowers, and it extends the whole length of the garden. It is arranged ribbon fashion, and the long wavy lines of flowers were very beautiful. At the east end of this garden is the historic Raby Castle Fig which was planted nearly 150 years ago; it fills a house 40 feet long, and was bearing at the time of our visit the second crop of Figs. Many of the huge stems of this tree had been ringed, exhibiting the methods of former times to produce fruitfulness. Thanks to the rapid strides gardening has made in these last few years, this barbarous method is exploded. This tree still retains its wonderful producing properties and is in perfect health. The house is heated by a flue. On the top of the leads of the roof of this house, which overlaps the ventilation, has been trained a shoot of Ribston Pippin Apple, which was covered with fruit. Wending our steps westward along this magnificent border we catch beautiful glimpses of the park, which is very finely undulated. The wall of this garden

is well covered with fruit trees (many of the walls here are heated by hot-air pipes), exhibiting good taste in training. The varieties of Pears Mr. Westcott finds do best on the walls are Thompson's, Glou Morceau, and Williams' Bon Chrétien. Of Apples the great favourite here is Ribston Pippin for dessert, and which scarcely ever fails; the most useful and certain kitchen Apples being Lord Suffield, Keswick Codlin, and New Hawthornden. In the outdoor culture of fruit Mr. Westcott has much to contend against, as the atmosphere is very humid, and therefore sadly detrimental to the setting of the fruit and ripening of the wood.

We next enter one of the kitchen gardens, which is well stocked with small fruit trees, and see the parent plant of the justly celebrated Raby Castle Red Currant, and a host of other bushes of which it has been the progenitor. The wants of the ducal cuisine are immense, both as regards fruits and vegetables. Amongst vegetables of recent introduction Mr. Westcott speaks in high terms of Culverwell's Prolific Pea. About

Fig. 49.—RABY CASTLE—SOUTH SIDE.

1400 plants of Strawberries are forced in 5 and 6-inch pots; the pots are filled with the necessary compost, and the runners are then pegged in and allowed to remain uncut till the autumn. This method is found to save labour, and the runners have the advantage of the support of the parent plants for a lengthened period. Keens' Seedling, President, Garibaldi, and James Veitch, the latter being a great favourite, are the sorts employed for forcing. At the top of the kitchen garden is situated Mr. Westcott's house, which is a neat commodious structure, in a line with the conservatory. A fine ribbon border skirts the greater portion of the kitchen garden, and has for a background a magnificent collection of Phloxes in all the latest varieties, and on the opposite side of the walk, betwixt the conservatory and Mr. Westcott's house, were some fine Gladioli and Stocks beautifully intermingled, reminding us of some of the massive borders at Drumlanrig.

We come to the Pine pits, which consist of two fruiting pits, the varieties being Smooth Cayennes, Queens, and Charlotte Rothschild, the latter being valued as a winter Pine. The plants were very healthy, clean, and were showing some very fine fruit. In the fruiting Pine stove is a narrow border, in which pot Vines are planted out and trained over the pathway. After the Grapes are cut Melons are planted, and after them come winter Cucum-

bers, thus showing by judicious treatment how a little room can be profitably utilised; in front were the successional Pine pits, with a promising stock for future use. A little house contained plants of the Prince of Wales Capsicum, raised by Mr. Westcott. It is remarkable for its sturdy growth, which renders it invaluable for decorative purposes, its fruit being of a very pale yellow colour. We next come to the range of plant houses, the first house being 24 feet long by 19 wide, the roof of which is devoted to two magnificent plants of the white and red *Lapageria* interlaced. Never has it been our lot to see such a magnificent sight before, many of the white flowers measuring 4 inches in length, whilst the red was beautifully mottled. No one would begrudge going miles to see this lovely, and once seen never to be forgotten, sight. We noticed a fine *Gleichenia speluncæ*, *Nephrolepis davallioides*, and a magnificent specimen of *Todea superba* in a glass case, the plant measuring 5 feet across—a splendidly grown specimen. Next in order are two plant stoves, 43 feet by 20 feet, in which were a mixed collection of flowering and fine-foliaged plants and Orchids, all bearing the impress of high culture. An ingenious contrivance for decorating some of the ducal apartments used on state occasions to hide the bottoms of the windows merits notice. It consists of a species of *Vitis*, which is trained on a square

frame of about 4 feet high, in the inside of which is placed a Fuchsia trained on a lesser frame to fit. This has a most artistic appearance, and admirably answers the purpose it is intended for.

We now come to the range of glass, in which the experiment of the noted carrion Vine borders was conducted. The vineries are light, airy, substantial structures. They are 40 feet long each by 18 feet broad. The borders have been entirely renewed. The Vines for superiority of fruit and size of bunches are well entitled to rank amongst the best in England, and as such Mr. Westcott may feel justly proud of them. The borders are large, and consist of good loam; charcoal, lime rubbish, and a liberal addition of bones are used, and they have an annual dressing of bone dust. The following are the varieties planted in these vineries:—Mrs. Pince, Madresfield Court, Foster's Seedling, Golden Champion; this Grape was doing well, magnificent in colour and finish, it being grafted on a Muscat. Here also was the black Muscat grafted on the white. The third vinery contains Golden Champion, Muscat of Alexandria, and Venn's Black Muscat all full and good. The fourth vinery has been planted three years, and consists principally of Black Hamburgh and Dr. Hogg, which were in all respects very satisfactory, and gave promise of abundant future crops. The early vinery and Peach house are in the other kitchen garden, and had both finished off their wood well. For an early white Grape Mr. Westcott prefers Foster's Seedling.

In this kitchen garden are the Asparagus beds, which are 5 feet wide, covered with glass lights on a small span-roofed frame. The alleys are 4 feet broad; these in the spring are filled with fermenting material, the brick linings being pigeon-holed. In this measure the beds never fail in producing a sufficiency of this choice vegetable for the supply of the family. These beds are forced every fourth year, which gives them plenty of time to recover their strength. All kinds of vegetables are well and extensively grown, also Mushrooms, for which a suitable house is provided. Particularly valued amongst the vegetables is Veitch's Purple-top Turnip. Here also are the young men's rooms, arranged with hot and cold baths—an inestimable boon to young men who are exposed to so many vicissitudes of temperature.

In concluding our remarks on these noted gardens it is pleasant to record that Mr. Westcott speaks in the highest terms of the kindness he has received from the Duke and Duchess of Cleveland, who are both liberal patrons of and admirers of horticulture. Her Grace gives some of her spare hours to collecting plants of botanical curiosity, and places them under Mr. Westcott's care. Each department of these gardens bears the stamp of skilled supervision. Mr. Westcott is well known as one of England's best gardeners, he having received much tuition under the late Mr. Barnes of Bicton. Time did not permit us to note all we saw worthy of notice, nor was the day suitable for seeing Raby to advantage; still we saw much to admire, and the courtesy and hospitality of Mr. Westcott and his family we shall not soon forget.—B. COWAN, *Awrell Park*.

EARLY-FLOWERING CHRYSANTHEMUMS.

MR. W. TAYLOR remarked on page 253, in reference to early-flowering Chrysanthemums, that if grown healthily and well they will prove "real gardeners' friends, as they bridge over the time between the early autumn frosts and the regular Chrysanthemum season." There can be no doubt as to the great value of early-flowering Chrysanthemums for border decoration; indeed over a great extent of country they are the only varieties that can be relied on for producing an outdoor display; rains, frosts, and adverse weather generally occurring, which mar the beauty of the later blooms. Last year Mr. Freeman spoke approvingly of the early-blooming varieties, and submitted an excellent list of those that had succeeded in his garden in Yorkshire, requesting also the experience of others by which he might be able to extend his collection. Perhaps nowhere in England do better facilities exist for noting the relative merits of the flowers in question than at Swanley, where Mr. Cannell has nearly or quite five hundred varieties planted permanently in the open ground. During the first week in October the following amongst other varieties were in full bloom, and, seeing them, none could dispute their value for border decoration:—

Precocité.—Well described by Mr. Freeman as a "beautiful jonquil yellow;" flowers 2 inches across. A valuable variety.

Early Cassy.—Rosy lilac, faintly tinted with yellow in the centre; flowers 1½ inch across, of excellent form. Very free.

Adrastris.—Purplish lilac, hybrid Pompon; flowers 2½ inches across. Effective.

Gold Button.—Yellow; flowers small and button-like, not exceeding half an inch in diameter. A little gem. Free.

Mulle. Alphonse Dupré.—Hybrid Pompon; white, feathery, free, and early. Useful.

Lustre.—Pompon; small flower, very pale lilac. Free.

Lucinda.—Pinkish lilac, deeper in colour than the preceding variety, and a better formed flower. Good.

Madame Damage.—Clear bright yellow. Free, early, and useful.

Madame Pecoral.—Dark rosy purple. Very double, free, and fine.

Chrome Stella.—Pale chestnut; petals margined and tipped with yellow; flowers small and exquisitely formed. Distinct and attractive.

Delphine Cabouche.—Reddish mauve; flowers small, petals rather cupped. Distinct.

Illustration.—Pale lavender pink; early. A well-known useful variety.

Frederic Pelé.—Bronze red; flowers 1½ inch in diameter, and of excellent form. A valuable dark variety.

Little Bob.—A little brighter than the preceding variety, and the flowers smaller. Dwarf and free.

Nanum.—Creamy bluish; flowers 2½ inches in diameter, feathered. Free and very useful.

Others might be added, but those named are distinctly early—just expanding into full beauty when many other flowers are fading, and attractively "bridging over" the notoriously dull time referred to by Mr. Taylor. These Chrysanthemums afford cut flowers in profusion for indoor decoration, and render the gardens cheerful during the too often cheerless month of October, and hence they are eminently worthy of cultivation.—J. W.

GRAPES NOT COLOURING.

It would be interesting to know from different readers of the Journal if Grapes have coloured worse this year than they are in the habit of doing. One house of Black Hamburgs, which ripened with me in July, did not colour so well as I would have liked to have seen them. The crop was quite a full one but not heavy, and I was rather at a loss to know why every berry did not become jet black. Since then one or two later bunches produced by the laterals have coloured perfectly, and I am inclined to think the intense hot weather we had in July must have been unsuitable for Grapes colouring to perfection.

"R. P. B.," a good gardener, writing to the October number of the "Gardener" from East Lothian on this matter, states that Grapes colouring in that neighbourhood about that time failed to blacken, even in the case of very light crops. It is well known that too high a temperature is as bad for fruit colouring as a too low one, and if we could bear of two or three sure instances of Grapes failing to colour owing to very hot weather and too high a temperature, no doubt it would do much to prevent a similar result in the future, if the precaution was taken to form a shading of limewash, or something having the same effect, over the glass of vineries in which Grapes were colouring during excessively hot weather. As to the importance of trying to do something there can be no doubt, because Grapes not colouring is a more serious affair than many think who only consider it as detracting from their looks, for it impairs their keeping properties as well, and this often leads to serious loss.—A KITCHEN GARDENER.

ROSE SUCCESSION.

FOR one exhibitor amongst your readers there are, perhaps, ten thousand who are interested rosarians in respect to the production or enjoyment of their favourite flower; therefore I have thought it may be useful to those who seek the longest extension of that pleasure to supplement by my experience the valuable letter of "WYLD SAVAGE," in which he told of what he had seen at this late season at Cheshunt or elsewhere. I have about five hundred standard Roses lining the walks nearly a quarter of a mile in length in my high-walled garden, arranged under the auspices of my friend Reynolds Hole, with a view to their protection from wind. They have good loamy soil, and are annually mulched and cared for. The following have given me great and continuous satisfaction.

Charles Lefebvre, Mdle. Eugénie Verdier, John Hopper, Général Jacqueminot, Jules Margottin, Abel Grand, Jean Cherpin, La France, Maurice Bernardin, Victor Verdier, King's Acre, Madame Falcot, Souvenir de la Malmaison, Madame Domage, Comtesse d'Oxford, Sénateur Vaisse, Anna Alexieff, Beauty of Waltham, Marguerite de St. Amand, Marie Baumann, Gloire de Dijon, Marquise de Castellane, Leopold I., Dr. Andry, Madame Margottin, Annie Wood, Souvenir de Comte Cavour, Madame Caillat, Madame Charles Wood, Madame Crapet, Duchesse de Caylus, Prince Camille de Rohan, Miss Pole, François Louvat, Louisa Wood, Gloire de Bordeaux, François Arago, Exposition de Brie, John Gris, Safrano, Vicomtesse de Cazes, Lord Napier, Impératrice Charlotte, Duchesse d'Aoste, Pierre Notting, Louis Van Houtte, Madame Boutin, Sœur des Anges, Fisher Holmes, Vicomte Vigier, Monsieur Noman, Mrs. Bosanquet, Baronne de Rothschild, Céline Forestier, Dupuy Jamain, Belle de Bourg-la-Reine, Belle Lyonnaise, Ophirie, Madame Thérèse Levet, Duke of Edinburgh, Olivier Delhomme, Clotilde Rolland, Centifolia Rosea, Etienne Levet, Caroline de Sansal, Maréchal Niel, Pauline Talabot, W. Jessie, Madame de Cambacères, Sir J. Paxton, and Aimée Vibert.

Before the thunderstorm of September 30th all the above-named were either in full bloom or in well-developed buds, and therefore worthy of cultivation; as, of course, almost all were in unusual beauty in June, when many were abundant in flower beyond any year in my experience of thirty years. Last year, however, my Maréchal Niel produced a succession of three hundred good blooms, whereas the June rains this year were fatal to them.—A PUPIL OF REYNOLDS HOLE.

HARDY PERENNIALS AT WORCESTER.

IN a hasty run through Mr. Richard Smith's vast nurseries at Worcester a few days ago I noticed the following hardy herbaceous plants in flower as being particularly striking at this late period—viz., *Pyrethrum serotinum* (uliginosum), 5 feet, large, white, with yellow disc; *Silphium terebintha*, 6 feet, yellow, Composite with slender stem and Dock-like foliage; *Helianthus decapetalus*, 5 feet, all suitable for a shrubbery or back of border. *Rudbeckia hirta*, 1 foot 6 inches, yellow, blackish disc; *Asters amelloides*, longifolius, formosus, and grandiflorus; *Anemones japonica* and *vitifolia* (Honorine Jobert) in large clumps, both magnificent; *Salvia angustifolia*, tall, with small bright blue flower; *Catananche bicolor*, a free-flowering, purple, Everlasting-like Composite; *Caltha palustris monstrosa*, *Verbena venosa*, *Plumbago Larpentæ*, and *Oenothera taraxacifolia* (dwarf); *Delphiniums* William Pfitzer, double brilliant blue; *M. le Bihan*, tall, double, large, purplish blue; *Keteleeri*, Barlowii, and Palmerston, light blue, with white eye. All very attractive. *Pentstemons* Horace Vernet, Cicerone, Scarlet Gem, Lilac Gem, Delicata, Warrior, Narcissus, Racine; *Phloxes* Coccinea and Snowball (dwarf white), and many other showy varieties in full flower. Two good showy plants with variegated foliage at this season are *Ægopodium Podagraria* and *Lilium candidum foliis variegatis*, of which Mr. Smith appears to possess two distinct varieties.

I regret that the short time allowed me between the trains did not permit of more than a very cursory glance through this extensive place, where everything horticultural seems to be grown, and the whole district constitutes Mr. Smith's nursery, which is traversed in several directions by turnpikes, highways, and public footpaths, as well as by lengthy private drives ribboned on each side by the choicest specimen trees and shrubs in the most perfect health. The principal drive leading from the entrance in a straight line must be nearly a mile in length, and at the extreme end of this I found the Roses covering many acres, and anent which I will send you the few notes I was enabled to make. I hope this may not be the last I shall see of Mr. Smith's great and instructive plant manufactory, where, notwithstanding the vast extent, everything seems order, neatness, and regularity; but a whole week might be profitably spent over a careful examination of its horticultural treasures.—T. LAXTON, Bedford.

NOTES ON VILLA AND SUBURBAN GARDENING.

WE are reminded of the fast approach of winter by the falling of the leaves, which are now becoming troublesome and entail a great amount of extra labour to have them sufficiently swept up. Where Oak trees abound and acorns are plentiful these should be swept off the paths every morning, as they are most uncomfortable to walk upon. But the beautiful weather which we are now enjoying in the south is most welcome; and October so far,

instead of robbing the garden in one single night of all its beauty, has added to its effect, and is further most favourable for ripening the late summer growths of fruit and other trees which were made during the wet weather in September.

Flower beds are not yet divested of their beauty; but it is not safe to allow any plants that are wanted for next year's supply to stay out after this time, for frost may come suddenly and kill many of the tender plants. *Calceolarias* and *Verbenas* may yet be propagated from cuttings; in fact they often thrive better inserted now than when taken off earlier. A cold frame is the best place that can be had for propagating a stock of *Calceolarias*. Short stubby cuttings should be taken off and inserted about 2 or 3 inches apart in light sandy soil. They should have a gentle watering to cause the soil to become firm around them, and should be kept close for a few weeks, when air may be given them if the weather permits. *Verbena* cuttings are best placed in pans, pots, or boxes, and these in a close frame or pit.

As soon as the summer flowers are destroyed they should be taken away, and the beds be manured and dug in readiness to receive the spring bedding plants. No time must be lost for the planting of them, as it is on the earliness of planting that success in a great measure depends. Pansies, Polyanthuses, Daisies, *Silenes*, *Myosotis*, Wallflowers both single and double, and such-like spring-blooming plants, are the most suitable. Designs may be worked out as is done with the summer bedding plants; and most of the hardy plants named when fully out are indeed very showy. Care must be taken to plant the tallest growers in the centre of the beds or designs, reserving the dwarf plants for the edges of the beds. Wallflowers, *Myosotis*, and *Silenes* are all suitable for the centres of the beds or for back lines, while Daisies and Polyanthuses make the best edging plants. They will all do very well planted from 6 to 8 inches apart in accordance with the strength of the plants.

KITCHEN GARDEN.—*Asparagus* beds may be cleared of their haulm, which is now ripe. Celery requires to be earthed up, choosing fine dry days for the operation. Our plan is to place a tie around each plant, and then to bank up the soil as lightly as possible. Carrots are now at maturity, and should be taken up and stored for the winter in shallow heaps, with a layer of dry sand placed between and around them. Look over Onions and Potatoes that have been already stored for some time. We have grave complaints about the Potato disease, which in many cases was not perceivable until after the tubers had been stored for some days. Cauliflowers sown in August as recommended will require pricking out under handlights, in cold frames, or at the foot of a warm south wall; or if plenty of room and pots are at disposal some of the plants may be potted, than which there is no better mode of securing early produce. Plant Cabbage plants about 18 inches apart for the principal or main crops, choosing the strongest plants. We frequently plant them a foot apart every way, and in the spring take out every other row and every other plant, which when other vegetables are scarce we find very useful. We also prefer some of the smaller-growing sorts, as Wheeler's Imperial, Cocoa-nut, and Carter's Heartwell for early consumption. Plant Lettuces under handlights and in warm situations; also place a quantity of nearly full-grown plants in frames close together for use during the early winter months. They should be lifted with a ball of soil and carefully inserted again. Old beds that have contained Cucumbers and Melons are very suitable for receiving them. Spinach is now abundant and only requires to be kept free from weeds and thinned out, using the thinnings for cooking purposes. Any fruit yet remaining out should be gathered at once. Apples have coloured unusually well owing to the bright and dry weather.

GREENHOUSES.—These structures will now require attention. Everything must be placed under protection as rapidly as possible. Geraniums, which have been struck or old plants lifted, also all Azaleas or other hardwooded plants that have been placed out of doors during summer, must have their pots washed, and be placed under shelter forthwith. Attention must be given to preparing a stock of various plants for forcing purposes—Lily of the Valley, *Dielytras*, *Spireas*, *Callas*, &c. *Schizostylis* that have been planted out in the reserve garden for the summer must be lifted at once, potted, and placed under protection, and the plants will, if not allowed to flag, throw up at once an abundance of scarlet *Gladiolus*-like blooms. Dutch bulbs and hardy forced shrubs will make our conservatories gay after the *Chrysanthemums* have done blooming. The fine weather of late has been highly beneficial to *Chrysanthemums*, but it will not be safe to allow them to remain out of doors any longer, or the frost may injure some of the outside petals. We have had the pleasure of seeing several collections, and anticipate that there will be a splendid display this autumn. The plants are early, and the blooms will expand naturally—the very reverse to last season.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Storing Roots.—The main crop of Beet, Carrots, Scorzonera, and Salsafy, and a portion of the Parsnips should now be taken up

and stored for winter use. Avoid trimming the roots too closely or placing them in large piles, which causes fermentation, and the roots will either rot or grow. They are best put up in narrow stacks packed in dry sand in a cool moist place. In lifting and trimming Beet care is necessary to avoid damage, otherwise the colour will be damaged.

Plant out if not already done the principal crop of Cabbages for spring and early summer use. If there is likely to be a scarcity of greens in spring, or Coleworts are in request at that time, plant strong plants on a warm border 1 foot apart. They, if the winter be mild, come in early and are very useful. Tomatoes should be cut in clusters and hung in a vinery or other dry rather warm house to bring the fruit to maturity. Remove all yellow leaves from Savoy and other descriptions of winter greens so as to expose the stems to harden them for the winter. Cauliflowers should be gone over frequently, breaking the leaves over the heads of those most advanced, which will keep them clean and white, and be a protection against sudden frosts. This vegetable has been an uncertain crop this season, failing in many places, and the crops coming in in bad succession. Early London, Walcheren, and Veitch's Autumn Giant have given us an admirable succession; of the latter we are cutting heads of fine quality. Mustard and Cress, sow as required in gentle heat. Take advantage of every opportunity to earth-up Celery, as after this time it is liable to suffer from frost. Have protective material at hand to cover Endive and Lettuces in case of sudden frost.

FRUIT GARDEN.

Last week we gave a selection of fruits for walls; we now submit some good varieties for general garden and orchard planting.

Kitchen Apples.—Kewick Codlin, Stirling Castle, Worcester Pearmain, Lord Suffield, Hawthornden, Manks Codlin, Alexander, Lucombe's Seedling, Cox's Pomona, Peasgood Nonsuch, Cellini, Golden Noble, Warner's King, Rymer, Forge, Yorkshire Greening, Norfolk Bearer, Blenheim Orange, Lewis's Incomparable, Lady Henniker, Kentish Fillbasket, Tower of Glamis, Galloway Pippin, Small's Admirable, Betty Geeson, Northern Greening, Dumelow's Seedling, Bedfordshire Foundling, Alfriston, Royal Pearmain, Royal Russet, Striped Beefing, Hambledon Deux Ans, Winter Majeting, Norfolk Beefing, and Annie Elizabeth; some being useful for dessert. *Dessert Apples.*—White Joanetting, Irish Peach, Kerry Pippin, King of the Pippins, Cox's Orange Pippin, Court of Wick, Mother, Ribston Pippin, Mannington Pearmain, Claygate Pearmain, Margil, Golden Pippin, Kedleston Pippin, Reineette du Canada, Wyken Pippin, Lord Burghley, Old Nonpareil, Dutch Mignonne, Cockle Pippin, Pitmaston Nonpareil, Syke House Russet, Golden Harvey, Court-Pendu-Plat, Duke of Devonshire, and Sturmer Pippin.

Dessert Plums.—Early Mirabelle, July Green Gage, De Montfort, Oullins Golden, Green Gage, Kirke's, Jefferson, Transparent Gage, Golden Esperen, Purple Gage, Coe's Golden Drop, Reine Claude de Bayay, Ickworth Impératrice, and Late Rivers. *Cooking Plums.*—Early Prolific, Prince Englebert, Mitchelson's, Early Orleans, Gisborne's, Diamond, Prince of Wales, Victoria, Pond's Seedling, White Magnum Bonum, Autumn Compôte, Belle de Septembre, and Wyedale. *Damson.*—Crittenden's, sometimes called Farleigh. *Bullace.*—New Large (Essex) White.

Cherries.—Early Prolific, Knight's Early Black, May Duke, Elton, Buttner's Black Heart, Bigarreau Napoleon, White Heart, Kentish, and Morello are suitable for orchards. Walls are too valuable to be occupied with other than the choicest description of fruits.

FRUIT HOUSES.

Cucumbers.—Plant out the winter fruiters forthwith on raised hillocks as near the glass as possible. Those not having the convenience of a Cucumber house may secure fair supplies of winter fruit by growing the plants in pots or boxes, training the growths near the glass over the pathways in fruiting Pine stoves or other heated structures. Be careful not to overcrop or allow the fruit to remain too long, removing all deformed fruit in a young state. Maintain a night temperature of 70°, 5° less in the morning, 75° by day up to 85° with sun, admitting a little air at the top of the house at every favourable opportunity. The evaporation troughs should still be charged with liquid manure, and the floors damped at 8 A.M. and 4 P.M., dispensing with the syringe over the plants. Reduce the supply of water at the roots, but not to an extent to cause flagging.

Melons.—The end of the Melon season is approaching, especially as regards those grown in pits or frames, though any fruit that were cut with a goodly portion of stem will keep for a considerable time; but they should be kept in a warm house to thoroughly ripen before sending them to table. In houses, however, the supply will be kept up for some time longer. Sufficient moisture will be secured to the latest crop by damping in the morning and again early in the afternoon, affording water to the roots moderately—a supply once a week will be sufficient. All superfluous laterals must be kept cut out so as to afford the principal foliage the benefit of the autumn sun. Plants with fruits approaching ripeness should be kept dry, and a brisk heat maintained with rather free ventilation; the temperature keep at 70° at night, 5° lower in the morning, 75° by day, rising to 85° with sun, afford-

ing a little air at the upper part of the roof whenever the weather is favourable.

Figs.—Trees in pots to be forced early and now placed out of doors to mature the wood require to be taken under cover to keep them from the autumn rains. Any thinning of the shoots or cutting-back must now be done, and the surface dressing be completed. They should be kept in a cool airy house with plenty of air. Trees permanently planted out will in the late house soon be shedding their leaves, and must be kept dry with all the air possible. Any planting of fresh kinds or the making of new borders should be done as soon as the leaves have fallen, top-dressing also being done when the leaves have fallen.

Pines.—Plants on which fruit is now showing will afford fruit at a time when it is scarce and dear; therefore such plants should be afforded the best position in the fruiting department. Continue 70° as the minimum night temperature, 75° artificially by day, up to 85° or 90° with sun, closing at 85°, and maintain a growing atmosphere by sprinkling the pathways when their surfaces have become dry, occasionally sprinkling the plants also on fine bright afternoons. Maintain the bottom heat steady at 85° to 90°. The plants should be looked over about once a week, and if any require water supply it copiously at about the same temperature as that of the bed. Avoid overwatering the fruiters, as it causes the fruit when cut to be black at the centre. There is not always a certainty of Queens starting into fruit early in the season, but they do so readily by affording comparative rest after having made a good growth. Plants intended to show fruit early in the year should be kept at about 65° in the daytime by artificial means, 60° at night, ventilating at 70°, liberally above that, closing at 70°, allowing the bottom heat to fall to 70° but gradually. Water the plants only when absolutely necessary, very little will be required for those in beds of fermenting materials. Abstain also from sprinklings unless the houses are unusually dry.

Orchard House.—The ventilators should still be kept open by night as well as by day unless frost be apprehended, when they should be closed. Syringing will have been discontinued, or should only be resorted to to cleanse the foliage of insects. The watering must be reduced, but the soil must not be allowed to affect the foliage by becoming too dry, overwatering being equally injurious. Most fruits will be gathered, exceptions are the late Peaches and Plums. They will require moderate waterings, and should be together at an end of the house, so that they can be kept warmer by closing the ventilators at that part by night and ventilating moderately in the day, allowing the temperature to rise to 75° or 80° by day in bright weather, and if it fall to 50° or less it will tend to ripen the wood, which is of the greatest consequence. Remove, therefore, all superfluous shoots, so as to admit light and air to the remaining shoots and spurs to the fullest extent. So soon as the fruit is all gathered from the late Peaches and Plums the trees should have a good syringing to clear off any insects or dust. Fig trees not having the second crop ripe should be placed in a house with a gentle heat to ripen off. In many instances the trees will be shedding their leaves, those of Peaches and Nectarines retaining their green colour in some instances when fully ripe. They may be removed by drawing the shoots gently through the hand; but if ventilation be duly attended to this will hardly be necessary, as the air passing through will bring them down fast enough when ripe. Compost for surface-dressing should be had under cover at once, as it is best used moderately dry. Turfy loam, a fourth part of well-decayed manure, and a twelfth part of road scrapings or old mortar rubbish, with a sprinkling of half-inch bones, form a suitable mixture. All fruit trees in pots placed outdoors should now be surfaced, or as soon as the majority of the leaves have fallen, scraping out the soil to the depth of 2 or 3 inches or more, according to the size of the pots, replacing with fresh soil and ramming it hard. A good watering may then be given, the pots plunged in ashes to the rim, and the surface of the pots covered with about 3 inches of litter or cocoa refuse. Some consider the autumn rains have a prejudicial effect upon the roots. Such is not our experience. Pears, Plums, Cherries, also Apricots and Peaches and Nectarines, are just as well outside as in after the wood is thoroughly ripe. They are all upon hardy stocks, which suffer nothing from the autumn rains. Keeping the trees in the house dry at the roots often results in the buds being cast when the soil is moistened, the injurious effects of the drying system being also felt when the fruit is in its early stages, dropping instead of swelling, simply because there are no active rootlets to cater for them. When the trees are placed outside the house will be set at liberty for Chrysanthemums, Tea Roses, &c.

TRADE CATALOGUES RECEIVED.

Charles Turner, Royal Nurseries, Slough.—*Catalogue of Roses, Fruit Trees, Shrubs, Coniferae, &c.*

Thomas Rivers & Son, Sawbridgeworth.—*Catalogue of Fruit Trees.*

Osborn & Sons, Fulham.—*Select List of Plants for Forcing and Winter Blooming.*

Cranston & Co., King's Acre, Hereford.—*Catalogue of Fruit Forest, and Ornamental Trees, Conifers, &c.; also Catalogue of Roses.*

Thomas S. Ware, Hale Farm Nurseries, Tottenham, London.—*Catalogue of Florists' Flowers, Climbing Plants, and Roses.*

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

BOOKS (*A New Subscriber*).—The price of Dr. Hogg's "Fruit Manual" is 10s. 6d. Plants will be named next week. (*A Lady*).—Our "Garden Manual" contains the information you require and more besides, price 1s. 6d.

BACK NUMBERS (*J. B.*).—If you state the numbers you require we will inform you if they are in print; or if you order them through a bookseller he will supply such that he can obtain at 3d. each.

CLIMBING PLANTS (*C. A. C.*).—Notes on these will shortly appear.

PRESERVING FRUIT WHOLE (*F. J., Blackrock*).—The proper way to preserve fruit as indicated on page 259 is to place the jar of water in the centre of a box, the sulphur at one side of this jar and the Apples or any other kind of fruit at the other side. The fruit may be placed in a plate or basket, the latter I should say being the best, as the fumes would pass freely through to all parts of the fruit. The fruit is said to be preserved when the sulphur is all consumed; but should this not be found to answer, anyone could try the experiment of allowing it to remain in half an hour longer; when taken out the fruit may be stored away as if it had been gathered off the tree. —A KITCHEN GARDENER.

LAWN MOWER (*Daivy*).—Any one of those advertised in our columns would suit you. Write to the maker and state what you need.

FRUIT TREES FOR NORTH WALL (*Amateur*).—In "Work for the Week" in the last issue of the Journal you will find under the heading of select fruits for various aspects the information you require. We are unable to answer your other query relative to Mr. Beard.

SELECTION OF FRUIT TREES (*C. R.*).—If you consult "Work for the Week" in our last issue and also in the current number we think you will obtain precisely the information you require.

ALPINES (*Jean*).—Strictly speaking they are plants from alpine—that is, mountainous districts, usually requiring the protection of a frame in winter, because we cannot secure to them their natural covering of snow during that season. Gardeners, however, include in their lists of Alpines a great diversity of small plants difficult of cultivation. Many of them are best grown in pots, and require light sandy loam and peat, with abundant drainage.

EUCALYPTUS GLOBULUS (*W. D.*).—There is nothing unusual in the change of foliage alluded to. The change is natural and occurs regularly when the trees attain to the age and size that yours are—often, indeed, on trees about three years old. The leaves sent are very fine, and your tree is in excellent health. It is unusual for this tree to flower so far north as Darlington.

STOCKS FOR FRUIT TREES (*F. C.*).—Where the stocks are not specified it is implied that the sorts will thrive equally well on all stocks usually employed by nurserymen. When trees are ordered and the purpose they are intended for is stated, nurserymen generally take care that trees are sent best suited for that purpose. If dwarf trees and early fruitfulness are the desiderata, then Apple trees worked on the Paradise stock, and Pears on the Quince, will usually be sent; but if large orchard trees are wanted, then trees will be sent that have been worked on Crab and Pear stocks respectively.

DESIGN FOR A FLOWER GARDEN (*H. O.*).—If you will send us a rough outline on paper of your lawn, or give its length and breadth in feet, and if it is level or otherwise, we may be able to assist you.

ASPECT FOR GREENHOUSE (*B. H., Birmingham*).—A greenhouse having an aspect which the sun does not reach until 12.30 would be well adapted for the cultivation of decorative plants in summer, also for such plants as Calceolarias, Cinerarias, Camellias, Azaleas, bulbs, &c., in spring; but would not be suitable for Heaths and slender-growing hardwooded plants generally, which require abundance of light. With care in watering and efficient heating appliances ordinary greenhouse and bedding plants, such as Geraniums, &c., may be safely wintered in such a house, but one-third more of piping would be required than for a house having a south aspect. If we had not a better aspect than the one named we should not hesitate erecting a greenhouse, and should grow plants best adapted for such a structure.

ROSES FOR EXPOSED POSITION (*X. Y. Z.*).—If the site is very cold and bleak we doubt if the two Tea Roses you name, Catherine Mermet and Souvenir d'un Ami, will succeed. You may, however, try them as you live in the south. The other varieties included in your list are hardy. An excellent selection of Roses for an exposed situation is given on page 281 of last week's Journal. Order your plants during the present month, and request that they be sent as soon as they are ready for removal. Plant them in good soil immediately on their arrival, but do not prune them till the spring.

GRAPES DECAYED (*J. H.*).—The atmosphere of your house has probably been kept too close and moist, and probably also too cool when the Vines were in bloom, for we perceive the bunches have not set well. There is no remedy for the decay this year. You can only cut out the decayed bunches and keep the atmosphere of the house dry and well ventilated to arrest the decay of others. You do not say whether your Vines are healthy or not. Without knowing something of their condition we cannot advise you as to the best treatment to adopt in future.

PLANTING GRAPE VINES (*A. B.*).—Plant the Vines against open walls in November, and in the greenhouse early in March. Take especial care to shake the soil off the roots, and to spread them out their full length, pressing the fresh soil firmly upon them. Indian Corn should be sown in March.

HYDRANGEAS AFTER FLOWERING (*Sainfield*).—Cut off the flower trusses as soon as they fade. See that the plants growing in the open air have ample space for a full development of that globular outline natural to them and which renders them so ornamental, and no further care is requisite except protection from frost in winter; for as the flowers always come on the tops of the shoots of the previous year, these must be preserved intact or there will be no flowers.

SOIL AND SITUATION FOR THE WELLINGTONIA (*Agricola*).—The best soil for this Conifer is a deep rich loam, and for situation choose any spot where it is somewhat sheltered from high cutting winds, and where it has ample space to grow into a large tree. It requires no special treatment, only prepare a good station for it, plant in November, fasten securely so that it is not blown over by high wind, see that it does not suffer from drought next summer, and afterwards you may leave it to itself. Liquid manure is not necessary.

PLANTS FOR A GREENHOUSE IN WINTER (*A Lady Gardener*).—A temperature of 60° in winter will induce a premature growth in the Vines which you say you have in your greenhouse; it will also be quite 10° too high for Ericas, Epacris, and other hardwooded greenhouse plants. A temperature of 50° would enable you to have more flowers and a longer succession of them. Of Fuchsias for winter blooming take Dominiana, serratifolia, multiflora, and splendens; and of Geraniums of the Zonal class any of the following:—Astarte, Imogen, Mrs. Musters, Lady Sheffield, Lady Eva Campbell, Ethel, President McMahon, Mrs. Wright, Evening Star, Lady W. G. O. Elphinstone, and Vesuvius. The sorts of Violets you require are Victoria Regina, Belle de Chatenay, King of Violets, Queen, Princess Louise, and Giant. You ought also to have such inexpensive plants as Mignonette, Cinerarias, and Chinese Primroses. Some Hyacinths, Tulips, Crocuses, and Snowdrops should also be potted now, plunged in coal ashes out of doors, and brought into the greenhouse in small numbers throughout the winter so as to maintain a steady succession of their gay flowers. Some Myosotis, Delytra spectabilis, and Spiraea japonica might be potted now and placed in the house at once.

CULTURE OF AMARANTHUS HENDERII (*T. Watson*).—Place quite 2 inches of potsherds in the bottom of the seed pan, with a little moss or coarse leaf soil upon them to prevent the fine soil from being washed down among them; fill to within an inch of the top with fine, rich, gritty soil, which press gently down, then sow the seed, water through a fine rose, sprinkle a thin covering of soil over the seed, and place the pan in a brisk hotbed or stove. This should be done in March, and when the plants are large enough to handle prick them singly into warm soil in 3-inch pots, replace in the hotbed near the glass, give air to strengthen the plants on every warm day. Attend closely to watering, repot when necessary, using plenty of drainage and a soil of two parts leaf soil, one of loam, and one of silver sand pressed down firmly with an ample margin at the top for watering. Grow them on briskly in a lively temperature till the plants are sturdy, stout and strong, then remove them to a warm corner of the greenhouse well out of the direct draught from the ventilators, and with ordinary care they will soon bear full exposure to air and continue ornamental throughout the summer.

BOUNDARY FENCE FOR GARDEN (*Amateur*).—We know of no other substitute for a wall than a fence formed of boards. A boarded fence having a south aspect would enable you to grow and ripen such wall fruits as Apricots, Peaches, &c., and would render the border additionally valuable. A practical builder has informed us that the simplest and cheapest mode of erecting a plain fence is to insert posts about 3 inches square firmly into the ground at intervals of 6 to 8 feet, the sides of the posts to be grooved or to have grooves formed by nailing two slips to the posts at intervals a trifle wider than the thickness of the boards. In these grooves the boards are to be slid down precisely in the manner of "door boards" affixed to cottage doors where young children are given to wandering. By this plan the boards are not nailed but can move up and down slightly, as the boards shrink and swell in wet or dry weather. We should have the fence at least 7 feet high.

GOOSEBERRIES, CURRANTS, AND STRAWBERRIES FOR MARKET (*C.*).—*Gooseberries*: Antagonist, white; Crown Bob, red; Farmer's Glory, red; Leader, greenish yellow; Leveller, yellow; Queen of Trumps, greenish white; Keen's Seedling, red; and Red Warrington. *Currants*: Red Dutch and Ruby Castle, red; and White Dutch. *Strawberries*: Vicomtesse Héricart de Thury, President, and Elton.

UTILISING SHADED BORDER (*Thos. Blenkinsop*).—Your piece of ground will only grow such vegetables as suffer in hot weather—namely, Spinach, Lettuces, Turnips, and Cauliflowers, and others of the Brassica family. We should, however, plant it with shrubs, as Rhododendrons, Holly, Box, Berberis aquifolium, B. Darwini, common Laurel, Butcher's Broom, and Periwinkles, which would be more satisfactory than vegetables.

SCREEN FOR ASH PIT (*Jas. Shearer*).—Privet would be the most suitable and quickest growing of evergreens. The Oval-leaved (*Ligustrum ovalifolium*) is the best.

APPLES FOR EXPOSED SITUATION (*Idem*).—*Dessert*: Devonshire Quarrenden, Nonpareil, and Grey Leadington. *Kitchen*: Keswick Codlin, Norfolk Bearer, and Dumelow's Seedling.

MOSS ON TOMBSTONE.—"J. S." wishes to know "What would, at little expense, clear the growth of moss out of the letters inscribed on a freestone tombstone?" Can any of our correspondents oblige us with an answer?

PEAS FOR SUCCESSION (*A Lady*).—Your proposed kinds and times of sowing are good, and will afford a fair supply through the season.

CHIEFHUNT HYBRID ROSE (*R. P.*).—It is a vigorous grower, and would succeed admirably against an east wall. Maréchal Niel would not succeed against a north wall; the wood would not get sufficiently ripened.

AZALEAS ROOT-BOUND (*W. W.*).—The probability is, that if you pot them now the plants will push shoots from the base of the buds and not swell the buds. Defer the potting until the flowering is over, and then shift them into pots a size larger than those they now occupy.

PLANTING VINES (*Idem*).—They are best planted in the spring after growth takes place, but the canes should be cut back now to the length required. Vines that have been fruited in pots are not of much value for planting out, they are a rule not making a good growth as compared with those that have not fruited.

SELECT MELONS (*A Reader*).—Your query will be answered in an early number.

FERN FRONDS BROWN EDGED (*R. P.*).—Such an effect is often caused by a current of cold air. It is not unusual for the fronds to change colour at

this season. Your plant will probably be all right in the spring if you keep it in a healthy state.

WATER CRESS CULTURE (*An Old Subscriber*).—The trenches in which they are grown are so prepared, that, as nearly as possible, a regular depth of 3 or 4 inches of water can be kept up. These trenches are 3 yards broad, and whenever one is to be planted the bottom is made quite firm and slightly sloping, so that the water which flows in at one end may run out at the other. If the bottom of the trench is not sufficiently moist a small body of water is allowed to enter to soften it. The Cresses are then divided into small sets or cuttings, with roots attached to them; and these are placed at the distance of 3 or 4 inches from each other. At the end of five or six days a slight dressing of well-decomposed cow dung is spread over all the plants, and this is pressed down by means of a heavy board, to which a long handle is obliquely fixed. The water is then raised to the depth of 2 or 3 inches, and never higher. Each trench is thus replanted annually, and furnishes twelve crops during the season. In the summer the Cresses are gathered every fifteen or twenty days, but less frequently during winter; care is taken that at each gathering at least a third part of the bed is left untouched, so that neither the roots may be exhausted nor the succeeding gathering delayed. After every cutting a little decayed cow dung, in the proportion of two large barrowfuls to each trench, is spread over the naked plants, and this is beaten down by means of the rammer above mentioned.

ADDRESS.—We have received a very fine Cauliflower and some fruit to name, but have no letter in reference thereto. The address of the sender is necessary for the purpose of our reply.

PEARS DISEASED (*R. F.*).—The tree is evidently suffering from deficient root-action. Dig round the roots, throw out the old soil, and replace it with a rich compost. See if some of the roots have descended into the subsoil and have them cut off, raising the others near the surface.

VERBENAS (*T. G.*).—You should send the flowers to the Secretary, Royal Horticultural Society, South Kensington. They were not in a state to be exhibited when they arrived.

THISTLES (*Very Old Subscriber*).—The Thistle is *Carduus arvensis*, a dreadful pest. The only way to be rid of them is to keep cutting them; and when they are too short to be mown over, to cut them off close to or under the ground with a spud. You will never thoroughly eradicate them. All you can do is to prevent them gaining the mastery. Do not disturb the pasture; merely use the spud.

NAMES OF FRUITS (*Alexander Boyle*).—Gravenstein. (*J. Wilson*).—Van Mons Leon Leclerc. (*F. O. M.*).—1, Golden Noble; 2, Not known. (*L. Cheshire*).—1, Reineette de Canada; 2, Emperor Alexander; 3, Ross Nonpareil; 4, Sykehouse Russet; 5, Summer Golden Pippin; 6, Trumpington. (*W. Fisher*).—Cowanre Red. (*J. P.*).—1, Louise Bonne de Jersey; 2, Reineette de Canada; 3, Not known; 4, Bedfordshire Foundling; 5, Not known; 6, Flanders Pippin. (*A. W. Ayrshire*).—1, Golden Winter Pearmain; 2, Golden Noble; 3, Calville Malinre; 4, Not known; 5, Flower of Kent; 6, Fearn's Pippin. (*A Knutsford Subscriber*).—We believe the large one to be Cellini. The small one is Court of Wick. The Pear we do not know. (*S.*).—Triomphe de Jodoigne. (*Connaught Subscriber*).—We do not know the name of the Grape, never having seen it before. The spotting is singular. (*S. G.*).—1, Fearn's Pippin; 2, Lewis's Incomparable; 3, Joséphine de Malines. (*Dr. Bruce*).—Eyewood. (*Hampden*).—Apples: 1 and 2, Golden Noble; 3, Not known. Pears: 1, Beurre Langelier; 2, Beurre Diel; 3, Suzette de Bay. (*Lancaster*).—Gloria Mundi. (*J. Woodliffe*).—Apples: 1 and 2, Alfriston. Pears: 1, Triomphe de Jodoigne; 2, Van Mons Leon Leclerc.

NAMES OF PLANTS (*Juvenile*).—Hedychium Gardenianum. The other is some variety of Box. (*F. M.*).—We do not name florist's flowers, and the Fern is immature. 2, Is Nertera depressa. (*Jean*).—1, Aster capensis (Agatheae amelloides); 2, Phytolacca decandra. (*W. Minshall*).—Crimum asiaticum or an allied species, but the flower was too withered to determine certainly. (*Cranfordian*).—Lavandula Stæchas. Ferns immature. (*M. H. M.*).—Apparently *Carlina tinctorius*, but the specimen was insufficient. (*W. P.*).—Chrysanthemum segetum.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

THE MANAGEMENT OF HORNED EWES AND LAMBS.

THERE are various breeds of horned sheep in the kingdom, but our purpose at present is to treat of the horned ewes, natives of the counties of Dorset and Somerset, where they are kept in large numbers, and are the chief breeding flocks reared in some of the best and most extensive districts, particularly in the vales of fine grazing and arable farms to be found in both counties. We propose to confine our remarks upon this subject entirely to the management of this stock used for the purpose of producing early lambs for the metropolitan and other markets, for which purpose they are better adapted than any known breed of sheep. We select the present time for our paper upon this subject because this is the period when they are purchased to go into the home counties for the feeding off early root crops; especially are these sheep kept upon the sandy, gravelly, and dry loams in the counties of Hants, Sussex, Surrey, Hertfordshire, and Kent, and they are admitted by all the most experienced and practical graziers in these districts to pay more money with less risk and loss for the feeding of forward turnips, Swedes, &c., than any

other kind of sheep. We would, however, wish it to be particularly noted that we consider the management of this stock and their early lambs as the most difficult of any, and certainly requiring great judgment, experience, and foresight, together with the most careful and diligent superintendence. This breed of sheep are wonderfully improved within the past forty years; for although we have kept them ever since the year 1826 for the especial purpose of producing the earliest and fattest lambs, yet at that time they were an inferior race compared with what they have been since. When first we kept the Dorset ewes, although they would bring a large number of lambs and give an abundance of rich milk, yet they would after fattening their lambs be themselves comparatively poor and lean. Such, however, has been the improvement made in the Dorsets by crossing with the horned stock raised in the best grass districts of Somersetshire, that instead of being reared as formerly almost entirely with regard to milking qualities and their propensity to produce twin lambs, in doing which the shape and fattening quality of the ewes had been very much lost sight of, now we never meet with any of the old speckle-nosed Dorsets, the improved breed prevailing throughout both counties. The flocks differ according to the nature of the soil upon which they are bred and the pains and practical experience bestowed upon them by the breeders, and so particular are some of the best flock masters that they will not breed from a ewe having a black spot upon the nose or eyelid. We have in consequence a breed of splendid animals of beautiful symmetry, and this has been achieved without reducing the milking quality of the ewes, but by adding the valuable capability of fattening during the milking period, so that now when properly cared for both ewes and lambs go to the butcher simultaneously. There have however, been some mistakes made by the improvers of the horned ewes, and particularly in those instances where a single cross with the Leicester ram was used many years ago. This has improved the carcase and outline of the ewes, and given them a quicker aptitude to fatten, but it has ruined the tendency to produce the early lamb, and we have found it very difficult after this cross to induce the ewes to offer to the ram early and well together. It is a great drawback in the case of animals purchased at a high figure to find that they bring their lambs very irregularly—some in October, some in November, and the remainder in December, because we have found that the ewes which drop their lambs in the month of October will be fat when their lambs are sold, but this is not the case with ewes which lamb in December, although they may have all been kept alike and as well as it is possible to feed them. In making purchases of this kind of ewes it is necessary to either attend the fairs where they are sold in Dorset, Somerset, or Weyhill in Hants, or, what is better, to give a commission to a dealer who has been in the habit of attending these fairs, for these early lambing horned ewes are much sought for, and often under offer to former buyers from year to year; therefore a stranger often stands a poor chance of obtaining the best stocks of ewes, unless he takes them from a dealing man who buys on commission and has a connection formed by previous transactions.

We must now refer to the provision and manner of keeping the ewes on their arrival at the home farm, for they will commence dropping their lambs soon after they arrive, it being the practice only to put the rams with the ewes so that no lambs shall fall until a few days after the usual time of selling them. When making provision for the keeping of the pregnant ewes we generally sow Italian rye grass in the wheat in the month of March, which will show itself after harvest and give a quick succession of food for the ewes, and when folded off it will afterwards afford good pasture until Christmas. This is not only the healthiest for in-lamb ewes, but it enables them to give the largest quantity of the richest milk, so much so that we have known instances of ewes whilst suckling two lambs give half a pint of milk daily more than the lambs could take, for we always relieve the ewe's udders every day if distended, in order to prevent any inflammation in the udder, which often endangers the life of the ewe; besides

which, when milk accumulates in the udder it becomes not only distasteful to the lambs, but produces disease in them and cripples them in their joints like rheumatism, from which they never entirely recover. In order that the shepherd may properly attend to these matters we always have a catch coop in the field, so that the ewes and lambs may be examined once a day, and after they are accustomed to it they will walk into the coop at the call of the shepherd without being driven by a dog; indeed, for a long series of years we never would allow a dog in attendance upon the shepherd, as we know they are a fruitful source of disaster amongst ewes and lambs in various ways, and particularly whilst the ewes are heavy with lamb. A constant change of food is requisite for the ewes, for we find that the exercise consequent upon change of food and moving from field to field advantageous, gentle and regular exercise being essential to healthy pregnancy. We do not like to turn in-lamb ewes into luxuriant clover fields, and there to remain without change until they drop their lambs. This is too lazy a life for them, and is often the cause of their yearning dead lambs. Nor do we approve, when grass is abundant, of giving this sort of ewes before lambing any oilcake, as it only flushes the milk injuriously and inconveniently at lambing time. We prefer to keep the ewes rather short of grass until the lambs can take all the milk, which they can do generally at about a fortnight old, except in the case of twin lambs, in which case, after the lambs are a few days old, the ewes cannot be too liberally fed. Whilst the lambs are young and before they begin to eat, the ewes may be put into the best young clover during the day; but this is cold bad lying for the lambs at night time, for we often get night frosts. We therefore always remove them into the wheat stubbles at night, which is much warmer lying for them, and prevents the lambs being chilled and often crippled with rheumatism. As soon as the lambs begin to eat, which they will generally do at about three weeks old, although they may not be required to enter upon root-feeding on account of the abundance of grass, yet they should have a fold in the grass field, with a lamb gate so that they may go into it apart from the ewes. This will learn them to feed in advance of the ewes when they enter upon root-feeding, and a trough of food such as it is intended to give them when upon root-feeding should be placed in the fold in order that they may be taught and induced to eat artificial food at the earliest period.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour is now applied chiefly to the preparation of the land for wheat. The late heavy rains have stopped the autumn tillage in forwarding the land for next year's root crops; therefore if the vetches, rye, trifolium, &c., are all sown, the laying-out of dung upon the clover lea will be proceeding, and as fast as it is spread the ploughing and pressing will be done. Upon some difficult heavy land, where it has been properly tilled and prepared, the drilling of wheat should be done, the sooner the better, as it is none too soon for strong cold land; but the season being still early two bushels of seed per acre will be a sufficient quantity. If the land lies in small ridges the drilling should be done so as to have no seed in the furrows, and these should be struck out with the double mould board plough. Upon all land subject to injurious weeds the wheat should be drilled at 12 inches apart if the land is well manured. If, however, the land is not in good condition the distance between the rows of wheat may be 9 inches, so that in either case the land may be horse-hoed in the spring between the rows. Lifting potatoes must now be continued, and generally speaking one strong horse will be sufficient attached to a potato-lifting plough, and on any light and dry soil this is the most economical plan of taking up the crop; upon heavy land, however, after the autumn rains commence it will be necessary to use more power, and often compulsory to dig them with the prong. Still, in dry land the potato plough makes good work, and throws out the most of the tubers ready to be collected by women or boys, after which the lifting drag made by Howard does capital work, and will leave scarcely any tubers in the ground. The grazing farms are now stocked with sheep or are fast being so; and it is important, as the lameness arising from foot rot and the epidemic foot complaint prevails so much, or at least has done so for many years, the shepherds must pay particular attention, so that at the first outbreak, which usually occurs after heavy rains, they may be prepared with remedies, for it is said a stitch in time saves nine. So it is with the lameness in sheep, for when attended to at the first outbreak it is more easily kept under control. The animals only require to be looked over daily, and when they show lameness they are dressed the second day. Our remedy being complete, and one which we have used with uniform success for upwards of forty years, only reduces it to a matter of daily attention. We give our recipe for the foot rot or epidemic lameness, also the luer which occurs above the hoof. Take 3 ozs. of nitre, 8 ozs. blue vitriol, and 3 ozs. of gunpowder reduced to a very fine powder, to be well mixed with 8 ozs. of hog lard, it will then keep for use. It must, however, be borne in mind that no remedy can be effectual unless applied at the proper time and manner. On the second

day after the attack the foot between the hoofs will show an irritable reddened surface, and often with inflammatory bladders. These must be broken and the remedy rubbed in by the finger, and the animal allowed to stand upon dry straw for two hours after the application. By this plan the lameness has not injured our stock either of ewes and lambs or wether sheep; but in case the disease is allowed to go on without attention is a ruinous matter, and often produces greater losses than all the cost of cake-feeding. Many farmers object to the expense of constant attention; but let us suppose an extreme, and that by regular attention it employed one man his whole time; the week's wages are nothing as compared with the loss sustained by even a small flock of sheep, much less a large one. The men and women, too, will now be employed in taking up and storing the mangold and early-sown Swedes; and in case it is not convenient to take the mangold to a large heap they may be advantageously put into heaps, clearing the land about ten yards each way from the centre, and then cover with straw and earth, there to remain until a convenient season; but this is only recommended when the ground is too wet for carting away the roots, or when the horses are busy in wheat-sowing or otherwise. We sometimes get this work done by the acre when labourers are scarce, because women and boys are able to assist in such cases. The dairy cows may now receive cabbages upon the pasture, which is a clean way of feeding; but as soon as they lie in at night they should have them in their mangers. It is at this time of year especially requisite that all the animals on the home farm should have access to rock salt, where they can lick it when inclined.

AGRICULTURAL HALL POULTRY SHOW.

THE galleries of the Agricultural Hall are admirable for a poultry show—at least for the spectators of one. We suspect, and indeed heard, that the atmosphere at night was both disagreeable and prejudicial to the birds from the fumes of the gas below, which naturally rise. Poultry and Pigeon fanciers are certainly among the number of those who must long for the perfection of the new invention by which buildings are more easily to be lighted by the electric light. The poultry entries numbered nearly a thousand, and as in the majority of classes the birds were shown in pairs, the Exhibition was by far the largest one of chickens that has been seen this year. Considering that little over three-quarters of the year has run we thought it a wonderful Show, having regard to the strength and maturity of the exhibits. The art of producing size and mature development in birds of the year has certainly been mastered by many through the attention bestowed these late years upon poultry. We were pleased, too, to see hardly any such specimens as those which in other years have looked as if they had seen a New Year's day. The birds seemed well fed and attended to, and were supplied with green food.

Dorkings.—The Darks were both better of their kind and forwarder than either of the other kinds. The cup cockerel is a monster with fine frame and good comb. He seemed on the second day of the Show to have been fighting and had lost most of his tail; his feet are not good. Second capital in colour and form, the Hemel Hempstead winner; his comb had, however, lately gone over. Third a good and large cockerel, but with a badly twisted comb. Fourth a very leggy bird, quite like a Malay. Mr. Lingwood showed a massive and well-shaped a cockerel as is often seen, but with toes already much swollen. Two younger cockerels struck us as being good and promising and worthy of notice—viz., Nos. 8 (Darby) and 19 (Crewe). The pullets were a capital class of twenty-three. We have never seen so fine and forward a lot in October, though we were sorry to observe that many had a fattened-up look. First not so large as some others, but a beautiful pullet all round; we think she held the same position at Hemel Hempstead. Second a fine pullet much to our fancy. She has some silver in neck hackle and a lighter breast than some judges would like, but we always think it wrong to balance these small points of feather against real Dorking form. Third capital in shape and colour; we liked her as much as any in the class; she certainly has a sixth toe nail on one foot, but this is a small defect. The fourth had the best white feet in the class. Many others would win in an ordinary class. The cup Silver-Grey cockerel and pullet are very fine, especially the latter. There was no other really good pen in the class; wry tails seemed quite the rule and not the exception in the cockerels. In the second pen was a horribly wry-tailed cockerel with yellow hackles; we much preferred the third pen. Whites were very fair. We quite failed to see the *rationale* of the awards. In the first pen the cockerel was weedy and backward. The second cockerel was better, but squirrel-tailed. The third very yellow. In the five-guinea Selling class a good pair of Darks were first and fair Whites third.

Cochins.—We do not think Buff Cochins are this year up to the average of some years; at least, though we see individually fine specimens we do not see well matched pairs. The cup went to a remarkable pair of Lady Gwydyr's. The cockerel is a grand Cinnamon, and we are always glad to see birds of this hue winning when good in form; the colour of his hackles is quite lovely,

more really golden than can be seen on really Buff birds. His mate was a capitally shaped pullet, but in colour did not the least match him, being of a lemon-buff tint, beautiful in itself but not suited to so dark a cockerel. In the second-prize pen was again a rich-coloured cockerel with dark tail and heavily hocked; in the third pen another dark-tailed cockerel and a very fair pullet; in the fourth a very forward bird, now in the moult. Most of the pullets were but ordinary. All the four prizes for Partridge fell to the same exhibitor. The first-prize pair were deep in the moult, doubtless from the heat of the building. In the third pen were a grand pair, the cockerel very fine, but with his comb drooping a little; the pullet beautifully pencilled. One of the best marked pullets in the class, but with a small cockerel, was in pen 90 (Mrs. Gordon). In the class for any other variety Whites were first, a good pair, and worthy of a name so long famous for the breed; second were the wonderful green pair of Blacks we saw at Hemel Hempstead; third very white Whites, the cockerel particularly good; fourth Whites again, good in shape, but the cockerel a little yellow.

Brahmas.—Dark cockerels were a good class, superior to those generally seen last year, if not equal to those of some former years. First was a grand bird all round, of the Lingwood type, we think the first Hemel Hempstead winner; second with particularly bright orange legs, not a striking bird; third admirable in shape and style, but unfortunately loose in comb; fourth one of the largest birds in the class, but speckly in breast and grizzily in fluff. Among the unnoticed ones we liked a young but very promising cockerel shown by Mr. L. C. R. Norris; by the Crystal Palace time he should make a remarkable bird. In pullets first was a beautiful bird in marking, but not large; second the very pretty Silvers mated at Hemel Hempstead with the first cockerel; third a good-sized bird with very even breast marking; extra fourth short-legged with broad really black pencilling on white ground. This was a large and good class. In Lights the first cockerel was splendid in shape and hackle and far ahead of the rest; second a big and well-shaped bird, in the moult; third rather narrow; fourth nice all round. Pullets were a very large class: first was good in shape, very white in colour, with capital black hackle; second again very good, in pure ground colour; third a fine bird all round, promising to be a good hen. The pullets of this variety were much better than the cockerels.

Spanish.—The cup pair each showed great softness and smoothness of face, and were all round by far the best; second a nice pair in high condition, hardly up to the cup birds in quality of face. The cockerel in the third pen showed great length of face.

French Fowls.—Houdans.—We fear this breed, eminently one of size and stamina, are suffering from an exaggerated stress being laid on "leaf" combs. In the cup pen were a cockerel, grand in size though not good in carriage, and a very fair pullet. We liked the second pen; they were even in colour; the cockerel has a pretty comb and fine round breast, which is always a point in table poultry. The fourth pair were too dark for our taste; the cockerel had one of the desired leaf combs, but, as seems general, in combination with them a poor crest. Crèves.—The cup pen contained a cockerel with a fine crest, but with comb too much like that of a La Flèche, and a good pullet; second large, but cockerel deep in moult; the third cockerel was nice in head and crest, but squirrel-tailed. The Messrs. Fowlers' highly commended cockerel was the prettiest bird in the class for crest.

Hamburgs.—In the spangled class Silvers were first, not large in spangling; the cockerel was not healthy, and deficient in sickles. Golden were second and third. We preferred the latter. In the Pencilled class Golden were first; the pullet a forward and well-barred bird. Second Silvers, we did not at all like the look of the cockerel's comb and could not believe it natural. Third Silvers again, the cockerel's comb too broad and depressed, his tail nicely laced; the pullet was very good in breast marking. In Blacks the first were far ahead of the rest, being lovely in colour, and the cockerel's comb an honest one.

Game.—In Black Red cockerels we thought Mr. Dutton's second winner better than his first. Fourth a very nice bird, more forward in hackles than most. Mr. Lyon's two birds were deep in the moult, but must by-and-by distance most competitors; they are the sons of the famed hundred-guinea bird of last year. The cup pullet seemed a capital one, others had darker eyes than are generally seen in show pens. Time failed us to go through the Brown Reds carefully; they seemed a good average lot. In any other variety the cup went to a good Duckwing cockerel. Second was an undoubted Duckwing, third a rich Pile. In pullets all the prizes went to Duckwings.

Malays.—First a raw cockerel of immense length, second a very strong bird; third forwarder in hackle, but not so strongly built. In pullets first was well ahead, a rich dark Cinnamon; second very young; third a well-formed bird paler in colour.

Polish were a splendid class, which might well have been subdivided. First White-crested Blacks, very forward, and the pullet's crest beautiful in form. Second Golden, the pullet one of the finest we have ever seen, the cockerel, too, very promising; the same exhibitor's unnoticed birds, though young, were very good. Third Silvers, another capital pen.

Andalusians are indeed progressing and were a very good class. The cup pen had excellent laced breasts, and the cockerel grand head and form. Second a sprightly cockerel, and both well laced again. Third younger and very promising.

Sultans were a much better class than at Hemel Hempstead. Cup went to a pen of adults nice all round; the cock's comb and crest good. The cock in the second pen was in the moult; the third pen were rather dirty. A strange pair were shown in pen 536 (G. Furness), in colour like Golden Polish with feathered legs and Sultan form.

Lephorns were good classes. In the first pen of Browns was a good hen, but we could not see the merits of the cock. The cockerel in the second pen was a well-shaped bird, and the third pair were both well shown. We think the prevalent squirrel tail a great drawback to this breed; especially are they common in the otherwise pretty White breed. The cup Whites were far ahead; the cockerel is a grand bird; he might carry his tail better. Second were young and very white. Third large and a little yellow.

Any other Distinct Variety.—First La Flèche; we did not think them striking. Second Silkies, the pullet splendid in crest. Third capital Minorcas; we should have put them first.

Bantams.—The awards in the Game classes much puzzled us. The first-prize Black Reds did not match as to legs. Mr. Raynor's winning pair of Duckwings were a smart little pair. Blacks were forward and neat, not very small. Pekins came first in the Any other variety class, and Silver-laced second.

Ducks.—Aylesburys looked fine, but call for no special comment. The second-prize Rouens caught our eye as being very good; the drake deep and round in breast, which we think a great point. Pekins are a rising breed; they had fifteen entries; the third-prize pair were bred in 1878, and show the rapid growth of the breed. In Black Ducks first were small and very beautiful, specially the drake. In the second pen was a lovely Duck, but not such a drake as the first. Third were Cayugas. Fancy Ducks were few. Chiloe Widgeons first and Whistlers second.

All the winning *Geese* were Grey. The *Turkeys* looked fine, but are usually judged by the scales, and so the awards hardly the subject of criticism.

Langshans had four classes. We are somewhat interested in these, for evidently the breed is meritorious in some points—to wit, the hens and pullets nearly all looked as if laying in October, and we wish to give an important consideration to the question of whether they are a really distinct breed to Black Cochins, of which we have not as yet had any convincing proof. We especially regard the classes with a desire to see this difference. In cocks the cup went to a bird whose tail was represented by two streaming sickles; second was a thorough Cochins deep in moult. The first hen was fine and handsome and according to the Langshan type; second small and nondescript; third a large Cochins. In cockerels the cup went to a bird of some Langshan character; second was a bird in good glossy condition, which might do duty for a Cochins; third was more of the leggy type. The first pullet was very large and fine; second again good and of the Langshan type. In this class pen 957 (Skelton) was a fine cockerel, which in his proper class might have won.

From the immense size of the Show we must defer our notes on the Pigeons to next week. The arrangements for the sale of catalogues were simply abominable. On the first day we gave 1s. for what turned out to be nothing more than a bundle of leaves from the catalogue all wrongly arranged; on the second day we waited for hours to purchase one, but could not, and were only able to get another faulty one for more than the regulation price, while we were repeatedly tormented by passers to sell it again at a profit. Besides this inconvenience to visitors much must be lost to a show by such mismanagement of an important department.—C.

FAMOUS POULTRY YARDS.—No. 2.

CHARDLEIGH GREEN (MISS E. BROWNE).

THERE are poultry yards which are famous for the excellence of their inmates without being either expensive or elaborate in construction. We shall make it a point to notice some of these. Our aim in promoting the poultry fancy has always been to encourage its general development—i.e., the breeding of poultry by all classes who have room to do so on a scale adapted to the special requirements of each rather than the hasty starting of great and magnificent establishments. These are very useful in their way as models, but the best and most successful of them have grown out of small beginnings.

We promised in our account of Combe St. Nicholas Vicarage to relate something of a neighbouring yard to which we paid a visit. It is Chardleigh Green. We have so often seen the name of Miss Browne in the prize lists, and have seen in her pens such lovely Spangled Hamburgs and Spanish with such grand faces, that we naturally fancied they must come from runs and pens innumerable; but it is not so. Intelligent care and management are the first requirements for successful breeding. A trimly-kept creeper-clad house stands near the country road; here live the owners of the well known poultry and equally well known Newfoundland dogs. While waiting for Mr. Browne we admired the portraits of the famous dogs; prominent among them was that of the renowned champion, now, if we forget not, seven years old. We were somewhat disappointed when Mr. Browne, who by the way seems full of interest and knowledge of the birds shown in his sister's name, told us that no pains were now taken with the poultry—all had gone down, and were not worth looking at. To us all birds are interesting, so we begged to see what these were. First we were taken through the house into a neat and pretty garden. Under

the trees in a snug corner were a pair of Carolinas, drake and Duck, in their glory; they have a perfect little garden to themselves, pond and rocks and bushy retreats, all wired in, and all in miniature. They evidently appreciate it, and would hardly show themselves. Thence we went back through the house and across the road to the poultry yard; great indeed was our wonder here to discover the delusive depths of Mr. Browne's modesty. No poultry worth seeing! A whole troop of various kinds came rushing round. In a moment our eye caught in many a one signs of the highest breeding. There were Spanish hens, now in the moult, and so without the bloom of condition; but what faces! so large and smooth and well shaped. Then Silver-spangled Hamburgs, even now with that peculiar glistening sheen which one nowhere sees as in the moons of this breed; a Moony cock or two, and Silver-spangled cockerels of the utmost promise for the show pen. Many a cup-winner is not taken from a run all to itself, but just picked out of a yardful—the birds at liberty, and all the stronger for it. Next we went down a rich sloping grass field, and there were the whole flock of the redonatable Sainsbury Black East Indian Ducks, bought last winter by Mr. Browne, and their produce of this year, revelling in their element—a broad ditch which runs down to a pond. July is not a happy month for Ducks, but even then one could see the glowing green gloss on the earlier young birds and on some old ones. We have often dwelt on the beauty which number adds to the appearance of almost all birds. It struck us forcibly again; there were full sixty—some in the water, some out of it sleeping on the bank, some ranging over the grass, and a beautiful sight it was.

Lovers of good poultry almost invariably like to have everything good and well arranged. We cannot account for this, but have observed it to be a fact. From here Mr. Browne took us to the conservatory and dog kennels, each admirable for their purpose. In a row of luxurious kennels were the splendid stud of Newfoundlands. A sound from one or two was a warning to be wary. Woe indeed to trespassers at Chardleigh Green! A lot of five puppies about six months old specially astonished us for their gigantic size. Several were had out one by one, and were greeted in a very rough fashion by their brothers and sisters on being returned to the family circle. Lastly the renowned old champion was exhibited. He did not much like our looks, and circled slowly about, carrying a bowl in his mouth. We were not sorry that he was so well employed.

But we had not seen all the poultry. Down a lane was a detachment of Silver-spangles, in the most perfect place conceivable for white birds or those of delicate colours. Through a cottage garden we came to a large orchard, thickly overgrown with fruit trees above and rich with moist grass below. Here was the cockerel breeding pen. We have always thought a good show Silver-spangled cock the most beautiful of poultry, and were much disappointed that the chancier of this lot refused to be seen or found. We saw, however, his party of wives, and very pretty they were, though adapted for breeding cockerels, and not according to the exhibition standard. We have never been quite able to educate our taste to like the most heavily-mooned hens now shown; they are certainly beautiful when the spangles are evenly distributed, but we have heard it hinted, though we have never ourselves tried the breed, that Nature seldom gives great regularity to the heavy moons. For this reason and for beauty's sake we should prefer spangling something between that of show hens and these cockerel-breeding hens. Here ended our interesting and pleasant visit, and we end as we began by saying that without many or costly houses, and therefore without all the trouble of opening and shutting gates, letting in and letting out different lots of birds—high class strains of one or two breeds can be well kept for pleasure and successfully shown.—C.

VARIETIES.

WE have before us the schedule of the seventh Oxford Poultry, &c., Show, to be held on the 30th and 31st inst. There are forty-nine open poultry classes with cup, second, and third prizes in each, and fourth prize in some. Among the less common classes are those for undubbed Game cocks, Andalusians of any age, Silkies and Sultans of any age. There are six classes for Ducks, including one for Pekins, one for Mandarins or Carolina, and one for Any other variety. There is also a class for Pheasants. There are five selling classes for large poultry, one of Bantams, and one for Ducks. There are no less than seventy-five classes for Pigeons. Dragons are specially well treated with fifteen classes and Antwerps with eight. We should remind our readers that entries close on Saturday next 19th inst., and that at Oxford the day is strictly adhered to. We have also just received the Crystal Palace schedule, which is materially improved and enlarged. We will review it fully next week.

— MESSRS. E. WEBB & SONS of the Royal Seed Establishment, Worsley, Stourbridge, intend holding their Great Root Show at Curzon Hall, Birmingham, on November 20th and 21st. Prizes of the value of nearly £500 are offered for competition by their customers at various shows during the season, including twenty-seven silver cups. The entries for root crops for competition at the

Show in question in Division 5 for crops of 5 acres of Swedes and 3 acres of mangold wurtzels close on October 23rd next, whilst those for specimen roots, potatoes, vegetables, and cereals (Divisions 1, 2, 3, and 4) close on November 13th, and that the latest day for receiving specimens intended for competition is November 15th. All exhibits must be sent per goods train, carriage paid, addressed to Webb & Sons, Curzon Hall, Birmingham.

—At the Kilmarnock Poultry, &c., Show, which is to be open under distinguished patronage on November 22nd, twenty-one mantlepiece timepieces are offered in the poultry classes as special prizes, in addition to the money prizes; eleven timepieces in the Pigeon classes, six in the Canary, and two in the Rabbit classes, making a total of forty timepieces. The schedule comprises eighty-eight classes, exclusive of those for Canaries and Cage birds. The entry for money prize in each class is 2s., for money prize special 3s. Entries close on November 9th.

—At the third National Columbian and Bantam Show announced to be held at the Winter Gardens, Southport, on the 30th and 31st inst., the following special prizes are offered for Pouters:—To the amateur who wins the greatest number of points, cup value £3 3s. To the exhibitor of the best Pouter in lieu of first prize, cup or money, £2. The Norman Hill Challenge Vase, value £15 15s., presented by Capt. Norman Hill, London, to be competed for at Southport and at the Crystal Palace. First, this prize to be for the best standard Pied Pouter cock at the above Show (any age). Second, to be competed for until the same bird receives the highest award on three different (not of necessity consecutive) occasions. Third, this prize to be an additional or extra one, not intended to take the place or effect of any other prize or prizes at the respective shows. Fourth, birds competing to be the *bona fide* property of the exhibitor, making the entry for at least one month prior to each show. Fifth, birds to be judged in a judging pen not less than 3 feet square. Sixth, the judge or judges who adjudicate for this special prize to be acknowledged Pouter judges, whose reputation for impartiality shall be above suspicion.

THE STEWARTON SYSTEM.

SURELY "A RENFREWSHIRE BEE-KEEPER" in his letter on page 253 is too strong in his condemnation of the straw-skep system as distinguished from the bar-frame system. I have kept bees on a small scale for the last six years in skeps, and have derived much pleasure and some profit in so doing. No doubt the Stewarton system has many advantages for bee-keepers who have an unlimited amount of time at their disposal to look after and manipulate their hives, but there are many people like myself who have other occupation for the greater part of every day, and have very little time to devote to their bees.

I have always thought from what I have read in "our Journal" and in other papers that the bar-frame system requires much more time and attention than the one I now practise. It would be interesting to many of your readers if some apianian who has tried both systems would give us the benefit of his experience on this point.

There are two great advantages in favour of the straw-skep system; one is that the hives are much cheaper, and the other that they are more easily managed. This year has not been particularly good for bees in this part of the country, but although I have had two misfortunes (one being the loss of my first swarm) I am fairly satisfied with the result of my honey harvest.

At the beginning of the season I had two rather weak stocks of bees in 16-inch hives. I have taken 71 lbs. of beautiful run honey and 21 lbs. of honeycomb, and this is a neighbourhood not particularly favourable for bees.—EDWD. THORP, *Salce, Cheshire.*

OLD COMBS AND FOUL BROOD.

WHILE by no means advocating the employment of combs to extreme old age, doing so, it must be borne in mind, does not necessarily induce disease. I remember referring to a case in the first volume, new series, of this Journal, of a farmer's wife preserving a straw skep which threw a couple of swarms regularly for twelve years.

Renewing brood combs annually as proposed by Mr. Pettigrew is an unnecessary waste of time and material to the bees; the combs are perfectly safe and serviceable for many years. The skilled gardener to renew his tree does not lop off all its branches at once, but removes every alternate first; and so with the skilled apianian, the removal being yet more easily effected with his moveable combs. Before the Stewarton hive was fitted with moveable bars or frames renewal was effected every two or three years by removing the uppermost breeding box with some thirty odd pounds of honey, the second taking its place, and a fresh one added to the bottom of the pile kept it continually rejuvenated.

Mr. Pettigrew has, however, evidently another and more pressing motive for the annual renewal of his combs, hoping thereby to get rid of a far greater evil—viz., foul brood. It is no disease of the combs, I having seen it in as virulent a form in fresh new comb as in old, the infection having been conveyed to both through the honey of infected stock. It has its origin in the

unsealed over-heated fermented honey or soured watery unsealed sugar syrup, the foul-brood fungi finding a congenial cradle in the decomposing matter of both, the larvæ fed thereon inevitably perishing, the disease gathering intensity as it spreads till the stock dwindles away.

Your readers cannot be sufficiently warned of the risk run in accepting condemned bees unless they have an opportunity of inspecting thoroughly the combs of the stocks from whence they were taken. The cottager naturally seeks to put down for honey the unprosperous skep, often infected with foul brood. Each driven bee carries with it its honey bag distended with contagion. They may be put together *en masse* and shaken out as recommended by Mr. Pettigrew like corn or peas, who all the while may be inoculating his fresh-combed stocks with the virus of the disease he is at such pains to try to eradicate.—A RENFREWSHIRE BEE-KEEPER.

OUR LETTER BOX.

CANARY MUTE SINCE MOULTING (W. W. Eyres).—He will resume his song, but the delay much depends on the weather.

LOSS OF HIVES (R. Wathen).—The loss of hives last winter was remarkable and pretty general throughout Great Britain. They were lost from want of young bees to take the place of those that died of old age. Last year bees ceased breeding at an unusually early period, and did not commence early this spring, hence the loss of thousands of hives, and probably yours amongst them. Hives this year are better stored with bees, and therefore more likely to live and do well. The supers on your three stocks should be removed, and the hives well covered with straw or other material to protect them from cold and wet. Contract their doors so that mice cannot enter.

WAX GUIDE-MAKING MACHINES (Zeno).—Write to Mr. Frank Cheshire, Acton, Middlesex, for one. Straw hives to be worked on the Stewarton principle should have their crown holes considerably wider than they usually are, and bars across these holes for the combs to be fastened to and built downwards, and thin boards to cover them till supering commences. The supers to be used should be 4 inches deep, and wider of course than the crown openings. The bees would and should have free access to the supers, and if tiers of supers be used all the bottom ones should have cross bars on their tops wider or broader than those on the hives below. You will see by looking at Mr. Briscoe's latest communication that in supering the Stewarton hive all the slides are removed, giving both bees and queens perfect freedom from bottom to top. If your straw hives are now peopled with bees let them remain as they are till they are full of bees in spring and require supers. Before using the supers cut out with a penknife three holes outside the central hole in the crown of the hives, say 4 inches long and 1 inch wide, then take the lid from the central hole and super as now suggested. If you want to run no risk take a wing from the queen before the supers are put on. Wax guides will help much, and may be easily fastened to frames of any size and single bars. With strong hives of any kind and free access to capacious supers furnished with guide combs you will not be disappointed with the results.

REMARKS.

- 9th.—Fine bright morning, very high wind, rather cloudy after 11 A.M., slight showers, heavy rain at 4.50 P.M.; fair evening; moonlight night.
10th.—Rain and high wind in night, heavy showers during the day, with intervals of sunshine; fine evening.
11th.—High wind all the morning, fine bright day; calm moonlight evening. Lunar halo 11.30 P.M.
12th.—Fine bright day throughout; rather misty in evening.
13th.—Misty morning; fine autumnal day, bright and calm.
14th.—Misty morning, fine sunny day; gusty afternoon; calm moonlight evening.
15th.—Calm cloudy morning; fair but dull all day.
The night of the 9th very warm, otherwise temperature generally much cooler than the previous week.—G. J. SIMONS.

COVENT GARDEN MARKET.—OCTOBER 16.

WE have no alteration to quote, prices remain the same and trade quiet.

From observations taken near London during forty-three years, the average day temperature of the week is 55.1°; and its night temperature 37.4°.

HARDY PERENNIALS IN MID-OCTOBER.

AT the risk of tiring your readers I must for the last time this season again take stock of the hardy perennial borders; for although we have had a little frost and much wind and rain, though Coleuses are shrivelled, Alternantheras almost leafless, and the ordinary flowering bedding plants are becoming altogether uninviting, there are still in the perennial borders in good condition some of the best flowering plants in existence.

Michaelmas Daisies are perhaps common plants, and there are many worthless species of them in botanical and other collections; but who can look on a good plant of *Aster longifolius formosus* with its abundance of bright rosy lilac flowers without admiration? A great point in its favour, too, is that it is self-supporting, requiring no ugly stakes—that great drawback to the beauty of herbaceous plants excepting where there is an artist to tie them up. It grows about 2½ feet high and forms a dense bush in a similar way to *A. horizontalis*, but it is very much better than that good old sort.

Aster Amellus is less in stature, being about 18 inches high, growing erect, and having its flowers arranged nearly as flat as a table all over the top; its colour is nearly blue, and it is very beautiful. *A. Amellus bessarabicus* is nearly a bright purple, and has broader petals than the type; it flowers three weeks or a month later than *Amellus*, is about the same height, and altogether distinct and good. *A. amelloides* is intermediate in colour between the two previously mentioned sorts, and although very good is not strikingly distinct from them. *A. ericoides* is 5 feet high, with an abundance of small white flowers, and has a very graceful habit. *A. grandiflorus* is just coming into bloom; it is 4 feet in height, and has large purple flowers. *A. pulchellus* is scarcely a foot high, and has fair-sized lilac flowers produced in abundance. *A. pendulus* is 4 feet high, with bluish-purple flowers, bright and distinct. *A. Novæ-Belgæ* is taller still, being 6 feet high, and of a reddish colour; it does well in a back row, and shows off to advantage against the large showy Ox-eye Daisy-like flowers of *Pyrethrum uliginosum*, also 6 feet high. Another back-row plant which is pretty well known is the double perennial Sunflower, *Helianthus multiflorus plenus*; this, too, is 6 feet high, and bright yellow in colour. The great Torch Plant, *Tritoma grandis*, is now coming up in all its glory and will last till December if the weather is not too severe; and the late-blooming Monkshood (*Aconitum autumnale*) is still in fair bloom beside it. It is a fine old back-row border plant for flowering late in the season.

The Japanese Anemones are pretty well known, but we never see too many of them; they are of such easy culture, and they look well in any conceivable place where they would be likely to grow; they are the best of flowers for cutting, and the most perpetual bloomers amongst hardy plants, that we can never admire them sufficiently. The pure white Honorine Jobert and the pale pink hybrida are, I consider, the best. They grow from 2½ to 3 feet high,

and produce larger and later flowers when transplanted than otherwise.

Schizostylis coccinea, like a miniature *Gladiolus*, is now throwing up abundantly its beautiful scarlet spikes about 2 feet high, and will continue doing so until Christmas unless the frost stops it. It flowers very freely, and is one of the hardiest and easiest plants to grow. *Tradescantia virginica*, of which there is a great variety ranging from purple and blue to nearly white, is still very showy. It is about 2½ feet high, and of very easy culture.

Gaillardias are rather uncertain plants, going off sometimes without any apparent reason, but they are very telling. *G. grandiflora*, 2½ feet high, with its large and almost gaudy crimson and yellow flowers, is now in perfection; and so, too, is *Centrocarcha grandiflora* (syn. *Rudbeckia fulgida*), yellow and black, even more beautiful than the Gaillardias, and of the easiest possible culture. This is also about 2 feet high.

The Cape Forget-me-not (*Anchusa capensis*) is still in good bloom; it is a little more than a foot high, and of a deep blue colour, even rivaling the true Forget-me-not. *Campanula Portenschlageana* is a pretty trailing plant, with purple flowers in abundance and a continuous bloomer; it would probably do well for bedding. *Cyananthus lobatus* is another trailing plant with light blue flowers, which are produced very freely all through summer and autumn. *Lilium speciosum* and its white variety are getting past their best, but in a northern aspect on peaty soil they are still very good. Some of the Colchicums, as *byzantinum* and *speciosum*, are gone; but we have still the double white, which is the best of all, the double lilac, and some single varieties, also the most beautiful of all Crocuses *C. speciosus*.

Altogether, although a few of the good plants enumerated last month have faded, we have others to replace them; and the borders are still very gay and interesting. The appended list contains, in addition to about seventy of those given on page 281, nothing but what is flowering in mid-October, and nothing that is not perfectly hardy.

<i>Aster acris</i>	<i>Francoa rupestre</i>
<i>A. amelloides</i>	<i>Funkia japonica variegata</i>
<i>A. Amellus bessarabicus</i>	<i>F. lancifolia</i>
<i>A. canus</i>	<i>Gaura Lindheimeri</i>
<i>A. dumosus</i>	<i>Gypsophila procumbens</i>
<i>A. Fortunei</i>	<i>G. speciosa</i>
<i>A. grandiflorus</i>	<i>Hypericum olympicum</i>
<i>A. leucanthemus</i>	<i>Lobelia fulgens</i>
<i>A. Novæ-Belgæ</i>	<i>Monarda purpurea</i>
<i>A. sericeus</i>	<i>Physostegia speciosa</i>
<i>Cedronella cana</i>	<i>Pyrethrum uliginosum</i>
<i>Chrysanthemum</i> , summer vars.	<i>Rudbeckia intermedia</i>
<i>Crocus aurea</i>	<i>Scabiosa caucasica connata</i>
<i>Crocus speciosus</i>	<i>Schizostylis coccinea</i>
<i>Cyclamen europæum album</i>	<i>Stokesia cyanea</i>
<i>C. hederæfolium</i>	<i>Tricyrtis hirta</i>
<i>C. hederæfolium album</i>	<i>Vittadenia triloba</i>

—WILLIAM TAYLOR.

[It is pleasing to observe that the merits of hardy border flowers are being increasingly appreciated, and that the plants are being cultivated more extensively than formerly; and the pleasure is enhanced, because this is not being

effected at the expense of other modes of garden decoration.—Eds.]

ABOUT VINES.—No. 1.

WHEN about to commence growing Vines the thing that surprised me most was the great diversity of opinion that was held by Vine-growers as to the best treatment. This diversity of opinion led me to conclude that Vines must be tenacious of life, and if they secured something like ordinary common-sense treatment they would make satisfactory returns. This being my third year's experience my early opinion remains the same. During the three years I have met with some disappointments and things to dishearten frequently, success also has been my share; but now partly across the stream how glad I feel when remembering the valuable experience I have gained by failures which once perplexed me. I fortunately have had many kind friends; but the inexperienced person who wishes to grow Grapes must not expect that advice is all that is needed, he must think for himself if he wishes to succeed. Let me here stipulate that my remarks are intended especially for amateurs, but at the same time if any advice I may offer by professionals be counted unsound, then I shall be glad if I should succeed in raising a friendly criticism.

Of my pleasures one is to make a clean breast as to how a thing is done. Secrets are not of my store, and I always look with pity on the person that is famed for his secrets. It will not be possible to speak of all the difficulties I have met with in one, or perhaps two or more articles; consequently I will begin at the beginning—Vine-raising, and then follow on in succession with my three years' experience.

When I commenced to plant my desire was the fashionable one—to procure strong canes; and I may here say, with what I procured I was so far satisfied that, did I require to purchase a fresh supply, I would willingly again purchase from the same gentleman. But experience has since taught me that strong canes are not the most desirable. What is wanted is a potful of healthy roots with just such a cane as no exciting treatment will furnish. A child 6 feet 2 at fourteen is something to look at, so is an extraordinarily strong cane the first season from the eye, but it is neither a natural nor desirable growth, and certainly not calculated the second season to do well. Stimulants to young Vines the same as to young children I vote a curse. During my short experience in looking round I have met with many planting canes and some fruiting canes that at the first glance have been fine to look upon, but after being turned out from the pots their roots have been only "mush." When it is decided to stimulate young Vines with guano—which at best I consider a foolish practice—its application ought only to be entrusted to the most trustworthy. Even one careless watering will so damage the roots that, however strong the cane may be, a Vine from the eye the season following will be stronger at the end of the first season than will the cane with the damaged roots by the second season of its growth. This I have proved.

My land being rather light I sought it all over for some soil a little stronger. On the side of the old fence where the watercourse had been dug deep out and the subsoil laid up against the fence for many years, I found some just to my liking; so the first season I secured all I could, added a little cow manure, and this year I have found this heap most desirable. Being desirous to raise Vines I determined, attain what size they might, to grow them in this compost, also to grow them in a cold house and to water them only with pure water. With this treatment I had the pleasure of stopping my canes at 6 feet, and their roots are something to be proud of. This, in connection with the raising of Vines, your readers will see is very simple treatment, as I will also show are many other of the treatments in connection with the Vine really necessary to secure success.—JOSEPH WITHERSPOON, *Red Rose Vineries, Chester-le-Street.*

THE PAMPAS GRASS AND ITS CULTIVATION.

GRASSES are a family that comprise a great many species, and form one of the very large bodies of the vegetable world. There is no region of the universe where varieties are not to be found, and what is there in the whole vegetable kingdom so useful and conducive to the health and happiness of mankind?

Of all the Grasses cultivated for ornamental purposes we think the Pampas should be placed first on the list. What is there more effective in pleasure grounds, or on lake banks, at

this season of the year than the spikes of this silvery giant waving to and fro with the breeze? Being a native of the prairies in the Argentine Republic some people imagine that moisture is its chief essential. These prairies, or pampas as they are generally termed, from which the plant derives its name, are not what many suppose them to be, vast tracts of marshy land; indeed, the ground is in most parts level, and at certain seasons pretty dry. As a proof of this we find when the Pampas Grass is planted in a shady wet situation in this country that it seldom produces flowers, yet how many plants do we find placed in such positions, and large specimens too? If by chance the plants thus placed do flower they only produce three or four worthless spikes, and this goes on year after year, until at last the plants are condemned as being a bad variety, while the whole cause of this barrenness lies at the root of the evil—of planting them in such situations.

Our largest specimen has thrown up sixty spikes this season, and is at present in full flower. It is 9 feet high, and the foliage, which hangs like a fountain in full play, covers a circumference of 45 feet. It is six years planted out from a 48-sized pot. Its position is due south, and stands in a bay of the tennis ground, sheltered from north and west by a background of tall shrubs. There was a pit dug out about 2 feet deep and 12 in circumference, and filled up with a mixture composed of chopped-up old pasture sods, lime rubbish, and cow manure trodden firm. When the flower spikes appear we give liberal waterings with pretty strong liquid from the cow house until the flowers are fully out.

I am convinced that the success in flowering these Grasses is due to their full exposure to the sun; they thereby get early and well ripened, and so the fact holds good in the case of the Pampas Grass as well as in all other plants and fruits—good ripened wood is the harbinger of success.—H. E. A.

TEA AND NOISETTE ROSES.

I VENTURE to send a list of twenty-five Tea and Noisette Roses which I can confidently recommend to readers of our Journal as most suitable for exhibition, appending a few remarks on most of the varieties I did not touch upon in my former communication.

Of course M^{re}chal Niel must head the list of all Tea Roses for what purpose soever wanted—garden, conservatory, decorative, or what not. But how seldom is this grandest of all Roses seen at all in the exhibition hall! and when seen hardly ever well shown, being either disproportionally large or small with its company, and especially is this the case in its own class among Teas or Noisettes. By-the-by, has any rosarian found out the secret of pruning the Rose (I do not mean against a wall or pillar)? Mr. George Paul's idea is the best I ever tried—to start with three plants (or some multiple of three), and cut-back hard one plant every year, so that each third year would give a plant with vigorous blossom-producing wood.

How so competent a rosarian as Mr. Charles Turner (in company I know with many others) can bracket Madame Bravy and Alba Rosea in his Rose catalogue, is a mystery to me. The former in true character is globular and much fuller, while the shape of the leaves of both entirely differs. That good old pot Rose Eugène Desgaches seems to me to run Alba Rosea much closer.

Is America grown as often as its merits deserve? I believe not. It is almost if not the only variety of its class which opens really well, and for its freeness of growth and hardness is eclipsed by few Roses. I remember seeing triplets of this variety exhibited at the good old Birmingham Rose Show, which were by many mistaken for that grand old Bourbon Souvenir de la Malmaison.

Belle Lyonnaise, though undoubtedly a first-class Rose, I find very uncertain except in autumn, and I seldom can bloom it even then in character; but a cousin of mine in the neighbourhood, with, perhaps, the difference of a slightly heavier soil, is seldom without splendid blooms in her garden, bearing out a remark I have before made about different rosarians having their different specialties.

In the group in which Souvenir d'un Ami is the acknowledged old favourite I have included in my list Souvenir de Paul Neyron, as I consider Comtesse Riza du Parc a far superior Rose where they differ at all in depth of colour and substance. Indeed, I consider this the finest new Tea Rose sent out for some time, as Madame Welsh I thought so highly of from two or three blooms I saw in the spring under glass will require

more time to mature its reputation, but I believe it will be a grand Rose.

Of the varieties of which Gloire de Dijon is the respected parent (and these are legion), I have omitted them all; they seldom open well, many not even under glass, and with me have only resulted in disappointment. Madame Berard, however, is a splendid exception, and both in the bud and blossom is always a great addition to the exhibition stand, giving that deep orange colour so conspicuous in the Safrano-Madame Falcot type, without their deficiency in size. Niphetos, a well-known, large, shell-shaped flower of the purest white, should find room in every collection, as when well shown its place never can be filled up.

Madame Margottin with its rich citron-coloured blossoms, and Souvenir de Monsieur Peron with its delicate peach tints, have both been specially glorious this year, and rank among the finest exhibition Roses. The same remark applies to that somewhat uncertain but well-known gem Rubens, when grown in character it cannot be surpassed.

Why my friend Mr. Camm gives so high a place in his election list to Julie Mansais I fail to see, for I never can get this Rose to open at all. I certainly saw a superb bloom of it exhibited at the Alexandra Rose Show this spring, but concluded it must have been grown under glass. Souvenir d'Elise and Souvenir d'Elise Vardon I think most rosarians will agree may fairly go in the same bracket.

Jean Ducher is a fine exhibition Rose of great size and substance, but it has a very great drawback, shared by H.P. Comtesse de Sereyne and some other Roses in producing its blooms as a rule of a dull dirty colour, caused probably by the running of the great variety of tints from palest yellow to dark red. President is a constant but rather small Rose, very free-flowering and of good habit, which Perle de Lyons of great substance unfortunately is not.

The following is my selection :—

Maréchal Niel
Madame Bravy
America
Alba Rosea
Belle Lyonnaise
Catherine Mermet
Marie Van Houtte
Souvenir d'un Ami
Comtesse Riza du Parc
Jean Ducher
Madame Camille
Caroline Kuster
Devoniensis

Madame Hippolyte Jannin
Madame Margottin
Niphetos
Perle de Lyon
President
Rubens
Souvenir d'Elise
Souvenir d'Elise Vardon
Souvenir de Paul Neyron
Triomphe de Rennes
David Pradel
Madame Maurin

—HEREFORDSHIRE INCUMBENT.

FORCING VEGETABLES.

SEAKALE.

ALTHOUGH the noble family it is my pleasure to serve does not consider Seakale a first-class vegetable we always keep a little of it in hand for variety during the winter; but there are many who value it highly and require large quantities of it. Fortunately for such it is not difficult to force, and a large quantity of it is just about as easily secured as a small one. The principal point to aim at in Seakale growing is to have it strong and tender. When cultivated in good soil in the kitchen garden the roots will generally be found in a satisfactory state for forcing, and to have it tender it must always be grown in the dark.

In order to have Seakale properly during the latter part of November, December, and January it is best to lift the roots and force them in a house. After that time they may be forced where they grow by placing pots over the crowns and covering them with a good quantity of hot dung and leaves. For early supplies the roots may be taken up as soon as most of the leaves are decayed. The quantity taken up at one time may be regulated according to the demand. Half a dozen 12-inch potfuls of good roots will furnish several fine dishes when there are ten to twelve roots placed in each pot. When the roots are lifted any long straggling pieces may be cut off, some rough stuff placed at the bottom of the pots, the roots then arranged round the edge, and the centre filled in with a light mixture of loam, Mushroom-bed dung, old leaves, or anything of that kind. The crowns should be a little above the surface of the soil, and the soil should be a little below the rim of the pot. After putting in the roots they should have one good watering, and then they may be placed in their forcing quarters. Whenever this may be they should have a brisk bottom heat to start them into growth in a dark place. Our Mushroom house

is so arranged that the Mushroom beds are along the back of a centre pathway, and the front is one large bed to force such crops as Seakale in. This bed is filled with long litter and leaves to ferment, and it is in this bed that our Seakale is forced. After plunging the pots in the bed nothing more is required until the Kale is ready to be cut, which is about three weeks after the pots are plunged. However, as every person has not a Mushroom house, I may say it may be forced as well in a dark shed, provided the requisite hot dung is placed there. We have made up the hotbed and then planted the roots on the top of it, but this we do not find answer so well as the pot plan.

When one batch of pots are done with they may be put in a cold frame and kept until the weather warrants their being planted in the open quarters again when it is desired to keep the old roots; but we seldom do this, as we prefer bringing forward young plants to coddling up old ones.—A KITCHEN GARDENER.

WINTER BEDDING PLANTS.

WORTHY of much more than the brief notice given in the report of the meeting was the gold-medal collection of miniature hardy shrubs, &c., exhibited by Messrs. James Veitch and Sons at South Kensington on the 15th inst. Such a collection was beautiful in itself, seasonable, suggestive, and instructive. The plants as arranged abundantly demonstrated that gardens need not in winter be destitute of colour, dull, and cheerless, but that flower beds may be made enjoyable, even bright, after the summer and autumn flowers have faded. The tasteful employment of such small Conifers, shrubs, and flowers as were included in the collection under notice are not only capable of rendering flower gardens beautiful during the winter, but the beauty is of a totally different kind from that of summer—a welcome change; a sober, chaste, and enduring beauty, not dependant on sunny days and genial showers, nor on watering, trimming, pegging, or pinching.

It is surprising how cheerful a flower bed on the lawn may be made by the employment of a few dwarf shrubs and Conifers tastefully disposed. Even the association of such a common shrub as the variegated Aucuba with a few feathery Retinosporas or Cupressuses, and the bright or light Euonymuses, will produce an effect at once cheerful and satisfying. Messrs. Veitch's collection contained these and many more winter plants that were distinctly ornamental, and yet the collection was only representative—a small typical example of the resources of the Coombe Wood nursery—a reminder that hardy winter decorative plants are about as plentiful as summer bedders, as varied in character, and in their way as attractive.

The collection included shrubs in various tints of green, some dwarf in habit, some bold, some feathery, others rigid; also shrubs remarkable for their bright variegation, as cheerful in appearance as flowers, and far more durable. Then there were flowering plants in variety and plants bright with berries, each having a beauty of its own and capable of retaining it, for all the plants are hardy.

Perhaps the shrubs with variegated foliage were the more conspicuous, and one of the brightest and quite the boldest of them all was Aucuba japonica limbata. The large foliage of this shrub is broadly banded with creamy yellow. A mass for distant effect would be very telling in large or small beds. Equally bright are the Euonymuses. These are indispensable for winter decoration, and dwarf compactly-grown plants are rarely injured by severe weather. A mass or band of E. japonicus aureo-marginatus is as bright almost as Calceolarias, and equally valuable is the smaller-leaved E. japonicus aureo-variegatus. Then for producing a creamy mass clear and effective is E. japonicus latifolius variegatus, of which it is impossible to speak too highly; and for a silvery line comes E. radicans. For contrast there are the green varieties, but only one can now be named—namely, E. angustifolius, dwarf, elegant, and shining, well adapted for divisional lines or edgings. Other variegated shrubs fine in a small state are the Gold and Silver Queen Hollies; and equally so, distinct and very effective, is Osmanthus ilicifolius argenteo-marginatus. Not to be omitted from this section are the Japanese Ligustrums L. japonicum tricolor, with large foliage and constant in its variegation, and L. ovalifolium elegantissimum, equally constant, elegant, and bright. Of very dwarf plants with yellow foliage are Buxus sempervirens aurea nova; Hedera arborea elegantissima, very compact and bright; H. arborea aurea, clear and bold; and Daphne elegantissima variegata, very clear

in its markings. *Eurya latifolia variegata* and *Eleagnus* were highly effective in the baskets, but they require very sheltered positions in the garden.

Some suitable green-foliaged plants and shrubs for associating with those having variegated foliage were represented by green Boxes, Aucubas, and dwarf Rhododendrons; *Azara microphylla*, elegant; *Veronica Traversii*, light green, attractive; *Sedum thymifolium*, dwarf and distinct; *Cotoneasters* and *Yuccas*. For forming a green carpet under trees were *Hypericum calycinum*, and the still dwarfer berry-producing plant, *Vaccinium Vitis-Idæa*.

Of flowering plants, most of them already flowering profusely and others in an advanced state, *Rhododendron Early Gem* is one of the most valuable of plants for in or outdoor decoration in early spring; *Andromeda floribunda* and *Catesbei*, *Veronica salicifolia*, dwarf *Laurustinus*; *Diplopappus chrysophyllus*, slender and Heath-like with white flowers; and the Heaths themselves. Most beautiful amongst these were the *Menziesias polifolia atropurpurea* and *erecta alba*, both highly attractive, the latter especially so; also *Ericas herbacea*, *mediterranea*, *vulgaris* in variety, *vagans*, *carnea*, and the dwarf and distinct *Mackayana*.

Amongst berried plants were *Skimmia japonica*, *Aucuba japonica vera*, dwarf and densely cropped; and the crimson *Pernettya mucronata*, all alike very ornamental. Besides the plants above named were the indispensable Conifers for imparting both grace and colour to the arrangement. Small plants of *Retinosporas*, *Cupressuses*, and *Junipers* are most valuable for various purposes of decoration in winter. Some are noteworthy for their bright colours, as *Cupressus Lawsoniana aurea* and *Retinospora obtusa aurea*; some are silvery, some green, some again elegant and feathery, others compact, but all ornamental and adapted for various purposes and positions. A few of special merit in this section were *Cupressus Lawsoniana aureo-variegata*, *albo-variegata*, *fragrans*, *lutea*, *argentea*, *erecta viridis*, *nana glauca*, *alba spica*, *macrocarpa*, *thyoides variegata*, *Nutkaensis* and *N. variegata*; *Cryptomeria elegans*; *Juniperus japonica aurea*, *japonica aureo-variegata*, *excelsa stricta*, and *Sabina variegata*; *Retinosporas obtusa aurea*, *leptoclada*, *ericoides*, *squarrosa*, *plumosa*, *pl. aurea*, *pl. argentea*, and *pl. albo-picta*; *Taxus baccata aurea* and elegantissima, *Biota orientalis aurea* and *semper-aurea*, *Thujopsis dolabrata*, and *Thuja Lobbi*.

Such were the more important of the plants included in the collection, and which are not only valuable for garden decoration in winter, but equally so for window sills and balconies in town and country. With plants of the nature of those enumerated there is no excuse for empty flower beds in winter except empty pockets, and yet the plants are by no means costly, especially when it is considered that they increase in value year by year if well managed.—J. WRIGHT.

TOMATOES.

In a late issue of the Journal it is stated that the Tomatoes in the market gardens about Fulham are very badly diseased; it is also the case with me, although not to the extent as stated to be there. The disease did not make its appearance till the forward fruit was fully grown, and it certainly bears a strong resemblance to the Potato disease, but whether it is the same disease or not I have never seen stated. I also find that it attacks some kinds more than others. The position outdoors and atmospheric changes make a difference. Cultural details were ably given lately, so it is unnecessary for me to enter into that; but this disease is rather a serious matter, so it would do no harm if cultivators of this plant would state their experience of it.

Early last June about 250 plants were put out here; 200 in the open to be trained to stakes $3\frac{1}{2}$ to 4 feet long, the rest being planted against the walls in vacant places between the fruit trees. All were strong and healthy when planted; they were a foot in height, and just showing their first flower truss. The varieties were Orangefield, Green Gage, and Hathaway's Excelsior, the majority of the plants being of the variety last named, which is one of the best sorts I am acquainted with. Being showery weather at the time of planting no water was given, nor has any been given since. The ground was rich and well pulverised, and the plants grew very luxuriantly, and weekly pinchings-out of the young side shoots and cutting away of all superfluous growth beyond the fruit were necessary, as one straight stem to a stake is quite sufficient. The plants on the walls were allowed to branch, and they were nailed

up as required, but all growths which were not wanted were suppressed.

The disease made its appearance first on the Orangefield variety, before the fruit began to colour; a week or so afterwards the Green Gage was badly infected with it, and at the present time all three kinds have it, but Orangefield and Green Gage are by far the worst. This applies to the plants in the open tied to the stakes, and out of 2 cwt. of fruit ripened from them one-fourth part has been thrown away diseased, some fruit slightly, and others infested all over.

From the fifty plants against the walls having south and

Fig. 50.—*Erica mammosa* (see page 315.)

south-east aspect only two fruits, or about half a pound in weight, have been bad; thus showing that although plenty of fruit may be grown without walls the produce can be depended on more with them, and although there are at present a great many left on them not a trace of disease is perceptible, but within 100 yards from them in the open it spreads very rapidly, especially after rain. This, I think, proves that a dry atmosphere is necessary for the ripening of Tomatoes, and when they are grown against walls showers sometimes do not touch the plants.

A three-light frame with boards at the bottom has been used for ripening the fruit, cutting them from the plants as they showed signs of colouring; a little air has been left on night and day to keep the atmosphere dry. Treated thus the fruit has ripened perfectly.

The plants trained to the stakes were 3 feet apart each way,

but all superfluous growths were thinned so as not to touch each other: had they been 5 or 6 feet apart probably a more free circulation of air about them would have helped to check the disease. Hathaway's Excelsior is an excellent Tomato, being very prolific, and having smooth, handsome, and highly coloured scarlet fruit.—A. HARDING.

DRESSING CARNATIONS.

It is now nearly thirty years since Carnation growers in the north commenced to exhibit their flowers on cards, and I well remember the observations that were made at that time by those who had not done so. This was at a provincial show where I used usually to put in an appearance. It was somewhat strange that the year after, at the exhibition held at the same place, those who had objected the year before exhibited their flowers on cards. One of them, an old and esteemed friend of mine long since dead, said to me that it was no use standing out against what was called at that time the "London fashion," as it was an improvement, and as such was sure to become general. How true his observation was everyone knows; and I believe that I am not wrong in saying that if the votes of Carnation growers and exhibitors (who ought to know best) were taken as to the advisability of dispensing with the card and dressing, they would be nearly unanimous in favour of both cards and dressing.

I see that "WYLD SAVAGE" has answered my questions in the *Journal of Horticulture*, but if he does not dress Roses does no one else do so? and as to exhibiting them, do not a great many exhibitors show them on a bed of moss? And this is done simply because the moss acts as a foil to the Rose and makes the flower appear finer than it otherwise would do if shown on a board. Consequently the moss is to the Rose what the card is to the Carnation.

As to dressing, I consider that to remove an outside petal (decayed or stained) is as much dressing to the Rose as turning back the calyx of a Carnation or pulling out a self petal.

With respect to those who can grow Carnations but not dress them, I am afraid their flowers if put into the hands of the most experienced dresser would be unable to win at an exhibition. The art, if art it must be called, is so simple that let anyone try with even a skewer there is no doubt but some improvement will be made in a flower.

With regard to Mr. Douglas not dressing his Carnations, knowing him well and intimately I can say without fear of contradiction that he can and does dress his own flowers; but when a man has to exhibit, as I have known Mr. Douglas do, about two hundred blooms, it is utterly impossible for one pair of hands to get through that quantity and have them fit. Consequently Mr. Douglas does, as others do, presses anyone who may be present to assist him so far as they can. I well remember an instance that occurred where four or five of us were staying for one of the National exhibitions. My friend had his flowers all dressed and in the stand ready for the exhibition next day. He placed them in the drawing-room. Of course there was any amount of visitors to see the flowers, and I am not sure if the gas was not lighted—the night was warm; the result was that fully one-half of the flowers withered up. In the early morning my friend cut another lot of flowers and was able to get them ready with some little assistance, without which he would have been unable to make up the number of flowers he wanted. In dressing I have frequently timed myself to see how long it takes to dress a flower, and found that the average time taken is ten minutes per flower. This being the case, where an exhibitor has upwards of two hundred flowers to stage he is compelled to have some assistance to get them ready.

The flower which was premier at Manchester was a fine Rose, and when cut was too young to dress, young flowers being difficult to manipulate owing to the brittleness of the petals and their tendency to split when touched. There was some dispute by one or two as to whether it or a flower in Mr. Booth's stand was best, but the decision was in its favour. After being judged the cutter florist dressed it and brought out the hidden beauties, when there was no cavilling as to its being the best flower in the exhibition. As to gum being used to the Carnation I never saw it, and, in fact, I do not know what use it could be put to. I have seen it used to Verbenas, which I suppose is the mode in which they are dressed.

A botanist friend of mine some twenty years ago used to say that all florists' flowers were monstrosities, and, of course, would not grow any of them, but preferred a common Dog

Rose or a single Carnation to the lot. However, as time passes on it brings changes. My friend is a florist; he has grown Carnations, Picotees, Auriculas, and Pansies; lack of room only prevents him from growing more. Of those who cavil so much at the dressing of the Carnations and Picotees I can only say this, Let them become growers, and I for one fully believe that they will become dressers. They will procure a pair of ivory tweezers and placing them and a flower together; they are so easy to handle, and the flower looks so much better for having the best petals made to show themselves, that the grower who has a good flower would, in my opinion, be very foolish not to show it to the best advantage.—GILLYFLOWER.

THE ROSE ELECTION.—No. 5.

IN the following returns of seventy-two varieties the Roses are placed as the first best twelve, second best twelve, next best twenty-four, and second best twenty-four exhibition varieties.

Messrs. KEYNES & Co., Salisbury.

* The first twelve are those which we would select supposing each Rose could be had in its best form on the same day.

NOTES AND GLEANINGS.

NATIONAL ROSE SOCIETY.—A meeting of the General Committee was held at the rooms of the Horticultural Club, Arundel Street, Strand, on the 22nd inst., the Rev. Canon Hole in the chair, when the Hon. Treasurer (Mr. W. Scott) submitted his accounts, showing a balance in favour of the Society. The dates for the exhibitions for 1879 were fixed, subject to the approval of the annual meeting. The first show is to be held at the Crystal Palace on June 28th, the second at Manchester on July 14th. It was also arranged that a paper of instructions on Rose-growing should be drawn up and widely distributed. It was announced that the "Rosarians' Year Book" would be issued, as last year, independently of the Society.

— AFTER an extraordinary term of dry autumnal weather in the neighbourhood of the metropolis, which has rendered street watering necessary and garden watering incumbent, a refreshing shower fell on Monday night. So dry had the soil become that we have seen such shrubs as Aucubas, Euonymuses, and Rhododendrons, where planted in proximity to large trees, with flaccid leaves and drooping shoots as if they were suffering from the drought of July instead of that of October. The rain has proved very welcome for such shrubs, also for accelerating the establishment of the recently planted autumn crops of Cabbages, Lettuces, &c., which were almost in a standstill state.

— A CURIOUS case of DICHROISM has occurred on a plant of the Dahlia in the garden of the Rev. R. H. Webb of Essendon, the author of the "Flora Hertfordiensis." The plant is a very old variety of double Dahlia, the flowers of which are yellow. This year one of the early blooms showed some red florets round the base, all the others being yellow as usual; but now a perfectly dark maroon flower has been produced on the same stalk as one entirely of the normal colour. Mr. Webb informs us that during the great number of years he has grown this variety no such occurrence has taken place before. Such instances are not rare in the Chrysanthemum, but we have never known it in the Dahlia till now.

— MESSRS. JAMES CARTER & Co. have been awarded FIVE GOLD MEDALS at the Paris Exhibition—namely, for seeds and a general collection of typical horticultural and agricultural produce, for lawns and Potatoes. Four of the medals are recorded in the official list of awards to exhibitors—the only record in the list of four similar medals being granted to any exhibitor—the fifth being mentioned in the French "Journal Officiel": the firm, therefore, have good reason to be satisfied with the result of their enterprise at the Great Exhibition.

— IN the garden of Dr. Rogers, the Warden of Sackville College, East Grinstead, there are several strong healthy plants of EUCALYPTUS GLOBULUS out of doors which have stood without protection for some years, and promise to become large handsome trees.

— NOTEWORTHY in Messrs. Veitch's collection of fruit arranged at the last meeting of the Royal Horticultural Society, yet not noticed in our report, were some tempting dishes of AUTUMN RASPBERRIES Belle de Fontenay, large, highly coloured, and excellent; Large Red Monthly, also good; and

the October Yellow. Autumn Raspberries are so useful and continue in use for so long that it is somewhat surprising that they are not more generally cultivated. We lately saw in Lord Londesborough's garden at Norbiton a fine quarter of Raspberries from which Mr. Denning has been gathering daily for months, he having sent many hundreds of fine dishes to the family which have been highly appreciated. Mr. Denning considers this one of the most useful of crops in affording a continuous and acceptable supply of fruit for tarts, and occasionally for dessert, for a large family.

— A CORRESPONDENT, "G. C.," asks if cultivators will give their experience with the LORD PALMERSTON PEACH grown in pots in unheated orchard houses. He had a good tree in a pot which ripened thirteen Peaches fine to look at, but they were tough and altogether uneatable. Our correspondent further asks if any special treatment is requisite to have this Peach in good condition.

— ONE of the most useful Fuchsias that we have seen for a long time is BLUSHING BRIDE. Unlike many varieties which are remarkable for their fine flowers the one under notice is of extremely free growth. Feed it well and it will produce fine sprays of flowers for cutting for vase ornamentation, while for conservatory decoration it is one of the most free in growth that has come under our notice. In habit it is erect, yet short-jointed and sturdy. It is a light variety, the sepals being white and corolla scarlet. When grown as we lately saw it in Mr. Cannell's nursery it is one of the most serviceable decorative Fuchsias in cultivation.

— MR. IGGULDEN writes to us as follows relative to a SECOND CROP OF PLUMS in Essex:—"In a preceding number mention is made by me of the extraordinary crop of Victoria Plums in this district. Since then the trees have produced a second crop consisting of several pecks of useful fruit. This was the case last season, but the crop was much smaller. Knowing from experience that they would not ripen, they were gathered and used in a green state. This phenomenon is attributed to the extremely hot and dry weather experienced during June and July, causing a premature ripening of the wood; the very humid August following had the very undesirable effect of causing the trees to bloom a second time. Pears frequently perfect a second crop of small fruit, but with Plums this is seldom the case."

— A VERY bright and cheerful display of ORCHIDS is arranged in one of the houses in Messrs. Rollisson's Nursery at Tooting. Numerous and highly attractive are the Calanthes vestita Veitchii and lutea; very fine are the Vandas, especially V. tricolor meleagris. There are also good examples of Odonoglossum varicosum, crispum, bigibbum, and incurvum, with Odonoglossum Roelzii, Pleione, and Cattleya marginata. In the nursery a bed of Anemone japonica alba is a mass of purity, and affords good evidence that this Anemone is one of the most valuable of late hardy-flowering plants.

— THE prolonged term of dry weather has had the effect of ripening THE GROWTHS OF CHRYSANTHEMUMS more fully than usual, and fine displays of this valuable autumn flower are being anticipated at the approaching shows. The plants in the Temple Gardens, London, are arranged under the temporary glass erection. The early varieties are just expanding; and although too early to judge of the individual merits of the flowers, it is not too soon to perceive that the display as a whole will sustain the repute of the gardens and Mr. Newton's skill as a cultivator.

— SWEET CHESTNUTS, writes Mr. Iggulden, "are plentiful and good this year. I have collected a quantity for use in the dining-room. The cook nips off their points, boils them till they are soft, then bakes them till they are dry, and when thus treated are delicious."

— A CORRESPONDENT writing from county Down on HYDRANGEAS IN THE OPEN AIR, states that for ten years his plants all died down from the frosts and shot up again in the spring, but never flowered. For three years he has covered each plant with poles and Spruce Fir branches, and they now flower luxuriantly every year—some with 130 trusses of bloom on each plant.

— WE are informed that the CELERY FLY has been unusually destructive this autumn in many of the market gardens of Fulham, notably those in the Thames valley, where the plants are almost devoured by the grubs. On this account many acres of Celery are being dug and hurried into the market as rapidly as possible, as it is considered that the crop

will deteriorate rather than improve if left in the ground now that the plants are nearly divested of their foliage. The unusual destructiveness of the fly is attributable to the remarkably dry weather that has so long prevailed.

— In the "Gardener" "ALBION" asserts that the laying of short grass between the rows of Carrots is a sure preventive against the CARROT GRUB. The system was adopted, writes "ALBION," "twenty years ago with the best results, the Carrot grub being unknown in the gardens where I was apprenticed. In a large garden in Banffshire, where the soil is light and poor, and the grub a continual pest among the Carrots, I advised the use of short grass between the rows, and a splendid lot of clean straight Carrots was the result. Since I have had the charge of a garden it has always been my practice to mulch

Fig. 51.—*Erica colorans* (see page 315).

heavily with short grass between the rows of Carrots as soon as the young plants are large enough not to be smothered with it, and I have always been able to store a clean lot. This year no grub has yet been seen, and some Carrots that I have pulled were quite 18 inches long. The Early Horns under the same treatment are clean and as good as anyone can wish. I am of the opinion that the grass keeps the ground moist, prevents the ingress of air, and makes the ground unsuitable for the grub to live; and the strong growth the Carrots themselves make under this treatment supplies a permanent shade, so that the soil about them can never get dry."

DOES THE MANETTI STOCK THROW UP SUCKERS?

In the notes on Slough by "WYLD SAVAGE" Mr. Gayter is reported to say that seedling Briars are worse for suckers than Manettis. I will again issue a challenge I gave one evening to some rosarians at the time of the Bath Royal Horticultural Show. I will venture to say a Manetti never produced a true sucker, and that in all cases so-called suckers are merely eyes left in the cutting of the Manetti stock. The Manetti, in short,

does not produce, like the Dog Rose, suckers from underground; roots coming up like fresh plants from the end of other roots, as we see in Plums, Peaches, &c., grafted on the Plum stock. Currants and Gooseberries, again, are supposed to make suckers, but my experience is they are invariably from buds under ground in the stock, and not like Raspberries, which form true suckers. I have never yet seen a true Manetti sucker, though I have seen plenty of underground shoots from the stem. When anyone will send me a root sucker I shall be willing to give up the point. I make this distinction: a sucker is like the wild growth of the Dog Rose, the Snowberry, or *Berberis aquifolium*, &c., a shoot rising from a root pushed from the parent plant, and not a shoot from the stem. I have seen suckers from a standard Rose coming up 4 feet from the stem with an intermediate underground root. I have seen Plum stocks send up shoots 8 to 10 feet from the stock; these are true suckers. Manetti suckers so-called, otherwise Manetti shoots, arise from mere oversight, or carelessness, or ignorance, or all three. I once saw in a nobleman's garden a bed of *Géant des Batailles* which I was called upon to admire for its growth, but asked why it did not bloom. I asked my noble lord if I might have a strong pair of scissors and a knife, and after cutting show him how much *Géant des Batailles* there was left. This was before breakfast one cricketing morning. I reduced the bed to *Géant des Batailles*, and the gardener's face was long and woebegone after breakfast. This is, I am afraid, an old tale, but literally more than three-fourths of the bed, and of course the strongest shoots, were Manetti, because the eyes had never been cut out nor the stems buried. I once again saw twelve named Roses sent to a neighbour, a baronet's gardener, who showed them me in glee as fine novelties to bud. Ten out of the twelve were cut from Manetti stock. The gardener would not believe me, but I told him to strike them instead, and not waste his stocks upon them; and next year he was obliged to allow they were very good stocks to bud on. I happened to see the Roses from which these presented cuttings to bud from were taken, and I found them a very healthy forest of Manetti. But these are days gone by, and very few gardeners are now taken in by Manetti shoots, though plenty are still taken in by the seedling Briar.—C. P. PEACH.

MELONS.

"A READER" wishes to have the names of the twelve best Melons, new or old, as to quality, and the names of the winning varieties of the year, particularly those at the Crystal Palace Show, September 24th and 25th, and also desires to know what a good Melon should be.

In reply it is necessary to premise that Melons are judged solely by flavour; size, weight, and appearance go for little, and what constitutes a good Melon can only be known to each individual, inasmuch as the palate differs in the same person from day to day; therefore, we can only say that Melon-judging is like tea-tasting, it requires adepts to detect high flavour—superiority of quality. There is, however, means of arriving at the quality of Melons by a comparison of them with varieties known to be of approved excellence, the flavour of which once implanted on the palate is so impressed on the memory as to be capable of detection whenever it recurs. Judging Melons by flavour is not, as some allege, a farce; but as appearance and superiority of cultivation have no influence in determining their merits, the person or persons adjudicating might as well make the awards blindfold. The ordeal of having to test the quality of three or more dozens of fruit when a glance at the exhibits would satisfy an experienced grower that first, second, and third rested with half a dozen fruit is simply needless. Quality by frequent and extensive testing enables the palate to estimate the values of the varieties subjected to it according to an admitted standard. For instance, Green Gage in Plums, Moor Park in Apricots, Noblesse in Peaches, May Duke in Cherries, Seckle in Pears, Ribston Pippin in Apples, Muscat of Alexandria in Grapes, and Queen in Pine Apples, have left their several impressions upon the palate, and by which other varieties may be judged by the standard there implanted.

It is similar with Melons. Richness of flavour is implanted on the palate by comparative testing and long usage. Anyone, therefore, to judge Melons or other fruit by flavour must have passed in review old as well as kinds at present cultivated, or he will not be in a position to pronounce a correct verdict.

A selection of the best dozen Melons:—*Scarlet-flesh*: Read's

Hero of Bath, Conqueror of Europe, and Bloxholm Hall. *Green-flesh*: Bromham Hall, Eastnor Castle, A. F. Barron, and Exquisite. *White-flesh*: Colston Basset, Cox's Golden Gem, Meredith's Hybrid Cashmere, and Queen Emma. All exceed 2 lbs. in weight. To a Melon of less weight we would not award a prize, nor test them when shown for flavour; miserable, ill-shaped, badly-grown fruit would not then be so frequently exhibited.

As to what a good Melon should be, I beg to submit—first, it should not be less in weight than 2 lbs. Second, it should be regular in shape, round or oval; if round, flattened at the stalk and opposite point like an Orange; if oval, the ends blunt or flattened, free from ribs or carbuncles or other irregularity of surface except netting, which should be even and extend over the whole surface; or if smooth it should be so throughout, or if only partly netted the netting should be confined to the stalk and point ends of the fruit. Third, colour regular throughout. Fourth, aroma not very powerful, the less the better, as it is given off in proportion to the softness or hardness of the rind—the harder it is the richer will be the fruit. Fifth, the heavier the fruit in proportion to its size the thicker it will be in flesh and higher in flavour. Those are the external characteristics of a good Melon. Such will have hard thin rinds, the flesh will extend to the centre of the fruit, and the seeds be embedded in the flesh without forming a hollow or seed cavity; the seeds will be comparatively few in number, there will be little or no watery juice in the centre as in those with a hollow or large seed cavity; the rind should not be less than an eighth of an inch in thickness nor exceed a quarter of an inch; the flesh tender, melting, and juicy quite down to the rind, with a rich sugary, musky, but agreeable, refreshing flavour.

It must be admitted that some ribbed Melons are thick in flesh and rich in flavour, but I find it very much more difficult to obtain by cross-breeding a Melon without ribs than with; and as ribs and pointed fruit with carbuncles only increase the quantity of the useless part—i.e., rind surface, it is only proper to reduce them to a minimum and seek to secure a maximum of usefulness, or secure flesh in place of useless exterior surface and hollow seed cavities. The vagaries of Melons obtained by cross-breeding are very remarkable. One instance will suffice. Beechwood \times Read's \times Victory of Bath has given a smooth, slightly ribbed, and netted scarlet flesh; a large, bluntly-oval, very closely netted green-flesh; and a large, round, ribbed, handsomely netted fruit, with thick green flesh, pronounced out of 150 fruit the best of the season; but the raiser thinks differently, rather regarding it as the worst out of over a dozen unnamed varieties. I mention this to show how cross-bred Melons run, also how tastes vary.

The varieties of Melons are so numerous and sport so much that it is not surprising to find so many of the prizes of the year being taken by seedlings, especially as there is no other test for the fruit but flavour. All the varieties named have won prizes, and many others named and unnamed—some positively ugly, more like Gourds, Marrows, and Pumpkins than fruit for dessert; yet it must be said some of the alleged new kinds are really beautiful in appearance and of unquestionable quality. One Melon we have omitted, but it ought not, being as it is one of the best—viz., Golden Perfection, it being a green-flesh of the highest excellence.

At the Crystal Palace Show in scarlet-flesh an unnamed seedling was first, Read's second, and Scarlet Gem third. In green-flesh an unnamed variety was first, Golden Perfection second, and Exquisite third.—A.

CAPE HEATHS.—No. 10.

OCTOBER.

ALTHOUGH these plants have been removed to their winter quarters long ago, yet the splendid open dry autumn we have experienced has not necessitated any protection whatever. Those in frames with us have had the lights all off, whilst in the case of larger specimens in the house every means of ventilation has been resorted to in order to admit the soft balmy air so beneficial to these plants during the present month. Mildew should almost be unknown, but still attention should be given that it does not creep in unawares and spoil the beauty and symmetry of the plants. Pay great attention to watering. Never give water when the plants are not dry, and when it is given let it be in sufficient quantity to wet the whole soil thoroughly.

Erica arbuscula.—A dense-growing beautiful little plant,

specially welcome at this season. Leaves short, spreading. Flowers terminal on the small branches, pitcher-shaped, red.

E. mammosa (fig. 50, page 310).—A most useful plant for decoration at this season. Free in growth, with linear subulate leaves arranged in fours, which are smooth, erect, and dark green. Flowers produced in long terminal whorls, wholly deep reddish purple.

E. princeps coccinea.—This variety usually blooms earlier in the season, but we have recently seen it in great beauty. Leaves linear, hirsute, fringed at the edges with ciliate hairs, deep green. Flowers long and tubular, produced in large terminal umbels, bright scarlet in colour.

E. casurgens coccinea.—Leaves arranged in fours, subulate, erect, and bright green. Flowers three times the length of the leaves, tubular, rich orange-scarlet in colour. The stamens are exserted and very conspicuous, adding much to the general effect.

E. cafra.—A neat compact-growing plant and an abundant bloomer. Leaves dense and bright green. Flowers small,

Fig. 52.—*Erica gracilis autumnalis*.

pure white, and very fragrant, which fully compensates for its want of size.

E. curviflora.—An elegant free-flowering species, which gives us a colour quite dissimilar to the majority of species at this season. Leaves linear, smooth, arranged in fours. Flowers curved, tubular, and clear yellow, terminal on the small branches, forming long racemes.

E. Bonviciana.—Leaves arranged in threes, glaucous, spreading, and distant. Flowers axillary, pendulous, white. The flowering shoots continue to lengthen for a long time, thus producing a succession of its charming blooms.

E. colorans (fig. 51, page 314).—A close-growing handsome species. Leaves arranged in sixes, hirsute, and deep green. Flowers terminal on the short laterals, forming long and dense racemes; colour white, changing with age to red.

E. grandinosa.—Leaves arranged in threes, linear, smooth, and bright green. Flowers also in threes, freely produced, ovate, pendulous, and pure white. This species usually blooms twice in the year—viz., spring and autumn.

E. versicolor longiflora.—A very handsome variety, differing from the species in the greater length of its flowers and in its season of blooming. Leaves in threes, linear, obtuse, smooth, and deep green. Flowers mostly in threes, terminal upon the small branches, tubular, with open mouth; colour orange and red.

E. gracilis autumnalis (fig. 52).—Leaves small, linear, smooth, and dark green. Flowers reddish purple, produced

in the greatest profusion on the ends of all the small branches, forming long dense spikes, which last a long time in beauty.

CLIMBING PLANTS.

OF the beauty and grace of climbing plants almost everybody has some degree of perception, for few can fail to find beauty where it is seen interwoven into forms so varied and colours embracing so wide a range, as is represented in plants of this nature. It must also be acknowledged that a thorough knowledge of the culture of such plants is by no means common. The sickly straggling growth that we so often meet with affords convincing proof that there are many to whom a few hints will prove useful as well as to "C. A. C.," who comes to us for help after "a three-years trial," ending in almost total failure, for he has only induced a Passion-Flower and a Virginian Creeper to grow freely, other plants, including such hardy vigorous climbers as Jasmines and Honeysuckles, either dying outright or making only weakly growth.

The query of our correspondent is a timely one, for the season of preparation for planting is fairly upon us, and by turning our attention to the matter at once we may reasonably hope for success. In planting climbers against the walls of a house we should remember that the work is not for a season—not even for a year, but rather for a generation or two. If the house be a new one children may be born, trained, and sent forth in the world bearing with them fond memories of home, among which the dear old Jasmine, Honeysuckle, or Rose will be cherished as things made sacred by many an incident when life was fresh and hope was bright. Let us therefore take especial care to lay well the foundation of our work by putting enough good soil alongside the house for the plants to root freely into for years to come, and also by making sure that the soil shall be well drained, of which there is considerable risk of its not being, unless special means are adopted to that end. Take, for example, a house with only a cellar or two behind under the offices. When trenches are excavated for the foundations they are generally cut down into a heavy mass of subsoil more or less retentive of water; the walls are built and soil thrown in to close the openings about the foundations, and if no outlet is made for drains through the subsoil down to the bottom of the foundations there is subsequently an accumulation of water from rainfall all along the bottom of the walls, not only making the house damp, but proving fatal to the roots of any climbing plants, no matter how hardy or tenacious of life they may be; or when a large bulk of soil excavated for cellars has been thrown out to form a terrace there is much risk of its eventually settling down into a compact mass and preventing the free escape of water after heavy rains. See, then, to the drains; open also a trench along the foot of the walls of the house, 4 or 5 feet wide and as much in depth, where climbers are to be planted; fill it with rich soil, precisely such as will yield good vegetables, with gritty matter or shattered stone or bricks to render it permanently porous, and you may plant your climbers without much fear of failure.

I have shown that imperfect drainage and poor soil are primary causes of failure. Another cause upon which I think undue stress is often placed is an elevated exposed situation. That this is a source of mischief it may be granted, but it ought not to lead to positive failure; on the contrary, by choosing varieties with stout foliage and of sturdy growth to mingle with and afford some shelter to more tender plants, there is no reason why a building should not be well clothed however prevalent high winds may be. The projecting angle of a lofty building fully exposed to south-western gales was so much wind-swept that the foliage of some Clematises and Roses was battered to pieces, and the plants consequently dwindled and presented an appearance the reverse of ornamental; a strong plant of *Cotoneaster microphylla* was therefore planted there, and it has thriven and made that part of the building quite as ornamental as the remainder. This plant may be named as quite the best for such a purpose. But there are others that bear exposure well and are very ornamental. Of such the best are *Escallonia macrantha*, with its stout handsome deep green glossy foliage and pretty spikes of deep pink flowers; *Escallonia pterocladon*, with smaller foliage and spikes of white flowers; *Ligustrum japonicum*, with bold handsome white flower spikes; *Cratægus Pyracantha*, with white flower clusters, followed by large berries of a deep orange colour; *Berberis Darwinii*, a general and well-known favourite, with stout glossy foliage and deep orange flower-clusters; *B. stenophylla* bearing a close resemblance to it, except in the colour of its flowers, which

are of a pale yellow; and in the south at any rate *Berberidopsis corallina* does not suffer from wind, and proves one of the very best of our evergreen climbers. It is not often to be met with in a flourishing condition, and yet once established in good soil it becomes positively rampant, throwing out dozens of stout shoots some 6 or 8 feet in length every season, forming a dense mass of stout foliage of a very deep green hue, and bearing charming pendant clusters of its deep crimson flowers throughout August, September, and part of the present month.

Climbing plants may usefully be divided into two sections—fast-growing sorts, which by careful training will soon climb to the top of the most lofty buildings; and slow-growing sorts, comparatively dwarf, and which are equally valuable in their way to mingle with the others, and to cover and make gay the lower parts of the building they so often leave bare. A select dozen species of the tall free growers may comprise *Ampelopsis Veitchii*, so beautiful now in the varied tints of its foliage, varying from a deep purple through crimson to brightest scarlet, and much more valuable than the old Virginian Creeper from its longer duration in full autumnal beauty and the admirable manner in which it spreads upwards and laterally with little if any assistance from the trainer; *Berberidopsis corallina*, *Jasminum officinale*, *Lonicera flexuosa*, *L. brachypoda*, *Wistaria sinensis*, *Escallonia macrantha*, *Aristolochia Siphon*, *Akebia quinata*, *Maréchal Niel* Rose, white and yellow *Banksian* Rose. Of the more dwarf or rather slower-growing kinds we may take the *Berberis*, the *Ligustrum*, the double-flowering and American *Blackberries*, a selection of the *Clematis*, *Cotoneaster microphylla*, *C. Simonsii*, *Fremontia californica* (worthy of a place in every selection), *Tea* Roses, and in the south *Ceanothus azureus*, *C. rigidus*, *C. divaricatus*, and *Desmodium pendulifolium*.—EDWARD LUCKHURST.

EXHIBITION ROSES.

MR. HINTON, in the interesting notes appended to the returning officer's declaration of the state of the poll, remarks, "I would like to start another subject in connection: What is the best time to cut Roses for exhibition? And again, At what stage should the Roses be cut from the plant?" On the former of these points something has been already written. I suppose the latter should be in such condition as that the judge might see it about two-thirds blown. But both questions contain interesting points for discussion, and both require a certain sifting, which if they could obtain it during the dull months in the Journal would supply matter that some of us, I suppose, always pounce on first, and also information which will be valuable to all next year exhibitors.

As respect the former question, I certainly prefer and always cut in the early morning. If I cut overnight and try the cellar they are sure to be discoloured. With the exception perhaps of two or three much-enduring Teas (Mr. R. G. Baker gave us not long ago a wonderful history of one such) I hardly know any Rose that would not be the worse for such a night's rest. I prefer cutting in the early morning with the dew on them, but I am by no means sure that these stand as well as those which open in the sunshine later. At a country show not long ago, where some exhibitors on the spot were bringing in fresh Roses and taking away weak blooms almost up to the very time of the judging, I noticed that these stood the hot tent certainly a vast deal better than others from a distance which had perforce all been cut early. We have also been told on high authority that Roses cut at 3 P.M. will travel through the night in better order than others cut in the evening. It is a matter of experience, and which I trust will draw opinion from some of our great exhibitors who have studied the subject on a large scale.

Perhaps the great question of all to be answered is, What Roses travel best? which requires careful observation as well as long experience. And this again may be put in another way, Which professedly exhibition Roses travel worst? I apprehend there are some highly placed in the twenty-four, or at any rate in the first forty-eight, to which some of us would be inclined to give rather a bad character. The time of cutting enters into the calculation, also the kind of day. I this year took a box of twelve to the Alexandra Palace, expecting to find two or three, as on former occasions, go off. It happened to be the beginning of a tropical week. After a couple of hours' railway journey seven out of the twelve, when the lid was taken off, appeared perfectly useless. They were fair average Roses, and such as would have stood under ordinary circumstances.

Looking at my notes I see that even Charles Lefebvre failed me on that occasion, also Victor Verdier, which perhaps is not much to be trusted, and Monsieur Boncenne, and also Comtesse d'Oxford. Star of Waltham, on the other hand, is the type of a class which is solid and enduring; also Baron Gonella, a Rose I have steadily and vainly voted for at elections. It is simply ignored by the exhibiting public. Annie Wood perhaps is not quite sure in the centre; but what a Rose this is! I marvel at her place now—so far below Marie Rady. At Marie Baumann's success I am not surprised. This was a Marie Baumann year. I saw some at Horsham of Mr. Sharp's, and Capt. Christy showed others at the Reigate Rose Show, almost, so to speak, as large as Paul Neyron, and yet losing nothing of the high tone or good breeding of which that robust individual is entirely innocent.—A. C.

HON. MARSHALL P. WILDER.

THE HON. MARSHALL P. WILDER is well known in every country of Europe as one of the most distinguished horticulturists of the United States of America, and more especially is he so as a pomologist. This excellent gentleman having attained the ripe age of eighty years, a banquet was given him on the 21st of September at the Parker's House, Boston, U.S.A. Pressure upon our columns prevented our noticing this interesting meeting until now.

EX-ALDERMAN BRECK presided, and spoke as follows: "We have assembled here to-day to honour one whom we all love and esteem, whom we all have known intimately for years, who is well known throughout the length and breadth of our country, and whose name in England, France, Belgium, and Holland is held in high esteem by the pomologists and horticulturists of those countries. We come here to-day to celebrate his eightieth birthday, and to wish him many years yet of health, strength, and vigour, and that his usefulness may be continued to his country for many years to come. I propose to you the health of our guest—Hon. Marshall P. Wilder."

COLONEL WILDER arose amid prolonged applause, and responded as follows:—Mr. President, I thank you for your kind expressions of respect, and you, my dear, dear, friends for the very cordial reception you have given me. Nothing could be more grateful to my feelings than these warm demonstrations of friendship and regard, coming as they do from those who have known me for many years and are conversant with my many frailties and faults. Yes, the wheels of time move on and tell the story of our bygone days; and if I live to see the opening of another sabbath morn I shall have passed the bounds of fourscore years. Most devoutly would I render thanks to the Giver of all good that he has prolonged my life, and that I am able to be here with you on this joyous occasion—here in the presence of my beloved pastor, who for thirty years has been my spiritual adviser—here with so many kind friends and co-labourers, with whom I have taken sweet counsel these many years—here to receive your friendly salutations, and, perhaps for the last time, to enjoy the sweet melody of your voices and breathe in the still sweeter consolation which arises like incense from off the altar of sympathising souls.

When we reflect upon our past labours our thoughts naturally revert to the Massachusetts Horticultural Society, whose fiftieth annual exhibition has just closed, and for which you, Mr. President, and your good father have done so much. Well do I remember its first exhibition in the old Exchange Coffee House in this city. Well do I remember the scene, with its two small side tables and one at the head of the hall. Well do I recollect the contribution of fruits when Robert Manning, the great pomologist of America, contributed only two baskets of fruit, and the subsequent growth of his enterprise when he donated many hundred varieties, and afterwards had in the Pomological Gardens at Salem two thousand varieties of fruit trees. Thank God, his son, bearing his own name, is with us to-day. Well do I remember the dinner, at which sixty gentlemen participated, and the speeches which succeeded it. The scene is before me now. There sat at the head of the table the eloquent Dearborn, there on his right and left sat His Honour Lieutenant-Governor Thomas L. Winthrop (father of our beloved Robert C. Winthrop), and His Honour the then Mayor of the city, Harrison Gray Otis, and the accomplished statesman and orator Daniel Webster of immortal fame [applause]. There, too, were Hon. John C. Gray, Vice-President; Dr. Jacob Bigelow, Corresponding Secretary of the Society, and John B. Russell, all of whom still survive; and here to-day, much to our joy, are the brothers Hovey, who were present on that occasion. Well do I remember the toast of General Dearborn—"Intelligence and industry, the only true promoters of the public good"—a sentiment which deserves to be written in letters of living gold. I thank you, Mr. President, for your kind allusion to me as one who has done something to promote the interests and welfare of my fellow men.

My friends, I have lived to see great progress and improvement

in the agriculture and horticulture of our country, much of which may be primarily traced to the enterprise and labours of Massachusetts men. Suffice it to say that from the day when Governor Endicott planted his Pear tree at Salem, which still lives; from the day that Peregrine White planted his Apple tree at Marshfield, Mass.; from the day when our Society was formed, it has stood prominently before the world as a leader and patron of agricultural and horticultural science. How marvellous the progress in our own day! How grand the march of horticulture since the establishment of our own Society! It is scarcely fifty years since the Massachusetts Horticultural Society was formed. Then there were only two horticultural and but few agricultural societies in our land, now they are counted by thousands, and are scattered over the continent, all working harmoniously for the promotion of these arts. Then there was scarcely a nursery of any note west, and only a few east of the Hudson River; now they are planted from one shore of our country to the other, and among them are many of the largest in the world. Then Mr. Hovey had not sown the seeds of his Strawberry and other fruits, which have since immortalised his name, or commenced laying out his extensive grounds and building his houses in Cambridge. Then I had not planted a seed of the Camellia, the Azalea, Pear, or Grape, or even attempted the hybridisation of a plant; now our American fruits and plants enrich the gardens and adorn the catalogues of foreign lands. Then we had no such splendid villas as those of Hunnewell, Payson, Gray, and others, with their broad lawns, extensive glass structures, and magnificent plants, which are such an honour to our land. Then we had many old and fine homes and gardens, such as Governor Gore's, Mr. Lyman's, Mr. Preble's, Mr. Cushing's, the Perkinses, and others; but very little in the way of landscape gardening, or in new or rare plants or fruits. Then our exhibitions were confined to a few days of the year, and were for many years held in small rooms; now many of our exhibitions are the best given in any State in the Union. Then we had no building of our own, now we possess the most costly and magnificent temple of horticulture that the world can boast. Then the American Pomological Society, whose President, by the mercy of God in his twenty-eighth year of service, now stands before you, had never been dreamed of—a society that emanated primarily from the influence of the Massachusetts Horticultural Society—a Society that embraces not only our national domain, but whose jurisdiction extends over our continent—whose catalogue prescribes the appropriate fruits for fifty States, territories, and districts, and at whose quarter centennial in this city the far-off state of Nebraska, with her Governor at her head, carried off triumphantly the Wilder medal for the best collection of fruits. Then there were few exports of fruits; now we send four hundred thousand barrels of Apples in good years to foreign lands. Then the Grape was scarcely cultivated; now, in addition to all that are used for the table, we make fifteen million gallons of wine, and wine, too, that took the first prize at the world's exhibition at Vienna in 1873. Then the statistics of our fruit crop were not thought worthy of record; now it amounts to \$140,000,000, or nearly the average annual value of our Wheat crop. But I must bring these remarks to a close. I thank you for the kind reference to me as a pioneer in rural affairs. You do me no more than justice, for I cannot, as I have told you before, remember the time when I was not fond of the cultivation of the soil. But, gentlemen, my labours are mostly over. Soon I shall be resting in the bosom of my mother earth; but if I can believe I have done anything to advance the great interests of our land, and which shall contribute to the happiness of my fellow men, I shall, so far as this world is concerned, die content, feeling that I have not lived in vain.

WORK FOR THE WEEK.

HARDY FRUIT GARDEN.

COMPLETE the gathering of Apples and Pears as soon as possible unless any of the latter do not part readily from the trees, when it is not desirable to gather them, as they will shrivel if gathered too soon. This more particularly applies to such late sorts as Bergamotte Espere, Fasse Crasanne, &c. Gathering Quinces, Medlars, Walnuts, and Filberts should be completed, keeping them in a moderately moist room, or they will become too much dried. Apples and Pears that have been stored some time should be occasionally examined, and all decayed fruit be removed at once. The room in which fruit is stored should be kept cool, but side ventilation should be employed as little as possible, as it dries the fruit in proximity too much without carrying off exhalations, which are best removed by top ventilation.

Wherever it is intended to form plantations of fruit trees the ground should now be prepared for their reception. Soils resting upon a heavy and retentive subsoil must be efficiently drained. Sandy soils often have water lodging in the subsoil; thorough drainage is then equally necessary as for heavy soil, but loams overlying gravel may not require drainage. If the ground be in grass it will only require trenching, and as the worst soil will be brought to the surface a good dressing of manure should be applied. Soils long in tillage will be improved by the addition

of fresh turfy loam, and if burnt clay can be had it will be a valuable addition. Sandy soils will be improved by a liberal dressing of fresh turfy loam, well pulverised clay or marl, and well decayed manure. Chalk is very desirable for soils deficient in calcareous matter, and old mortar rubbish is useful. The best time for planting is as soon as a majority of the leaves have fallen. The trees must be carefully lifted, their roots being kept moist, and be planted without any unnecessary delay. Where the soil is of a wet or heavy nature it is advisable to plant the trees upon hillocks elevated above the level of the surrounding ground. In planting any broken roots should be cut to sound parts and transversely, as slanting cuts retard the emission of fresh roots; the roots must be spread out carefully and the soil made moderately firm. We prefer to tread but lightly at planting, and to give in early planting a few cans of water to each tree, which tends to fill up any interstices, settling the soil among the roots and fibres. We leave a hollow, or basin, around each stem, which is filled in when the soil has become tolerably dry; it is then trodden down firmly, the trees being properly secured against winds, and a mulching of partially decayed manure is given around the stems outwards as far as the roots extend. This tends to check evaporation and to retain warmth. Any vacancies which may exist upon walls or espaliers should be filled up with healthy trees, but the old soil should for the most part be removed and replaced with fresh turfy loam. Where root-pruning is contemplated, it being necessary to check overluxuriance and to induce fruitfulness, it should be done as soon as the leaves commence falling, removing at the same time any useless or unnecessary shoots.

FRUIT HOUSES.

Vines.—Although this is not the time to plant Vines, yet the material for forming the border should be cut and laid up in ridges, and if sprinkled with soot and lime as it is being stacked wireworm and other insects likely to prove injurious will migrate. With so many good varieties of late Grapes the necessity for the forcing of Grapes to have them ripe very early is no longer desirable where the late kinds are largely grown. Lady Downe's Seedling is the most valuable of all, being a certain cropper and long keeper, keeping fresh and plump until May. Mrs. Pince is also a capital keeper, but requires to be ripened in heat like Lady Downe's to develop its Muscat flavour and to promote its good keeping properties. Alicante and West's St. Peter's are both excellent for keeping, and as a rule they finish off well without requiring so high a temperature as those with Muscat flavour. Gros Colman is simply magnificent in appearance, having splendid berries, and it has a fit companion in Gros Guillaume, both of which require a long time to colour and ripen thoroughly, but when that is done they are anything but coarse or inferior in flavour. They also require plenty of space and not too close pruning, and then they come out splendidly. Calabrian Raisin and Trebbiano are white Grapes with character not over-good as regards flavour; but when thoroughly ripened we consider the flavour is good, their appearance from the largeness of the bunch and berry fine, and they are capital keepers.

Where the above are not cultivated in quantity to keep up the supply to May preparation must be made for early forcing. The Vines having been pruned, the loose bark stripped off, the house thoroughly cleansed, the border top-dressed, and the Vines done over with a solution of soft soap, 1 lb to the gallon of water, brought to the consistency of cream with flowers of sulphur; adding, if there have been any scale, half a gill of spirits of turpentine, the composition being equally effective against mealy bug, killing all it touches. The whole being in readiness as advised in former calendars, cover the outside border with leaves and stable litter so as to warm the border, which should be done a fortnight before the house is closed and fire heat applied. If there be the convenience of making up a good bed inside the house of Oak or Beech leaves with about a third of stable litter it will greatly facilitate the Vines breaking, and be more beneficial to them than fire heat alone; therefore have these in readiness for placing in the house the early part of next month. Vines, however, to produce ripe fruit in late March or early April are best grown in pots as stated in a former calendar, selecting early sorts, as Buckland Sweetwater, Foster's Seedling, White Frontignan, and Golden Hamburg in white Grapes; and of black, Black Hamburg, Mill Hill Hamburg, and Royal Ascot. They should now be housed preparatory to starting them early in next month. Keep a sharp look-out for decayed berries amongst ripe fruit, as one decayed berry soon spoils a bunch. Ventilate freely by day in favourable weather, maintaining slight warmth in the pipes when the outside atmosphere is charged with moisture, and a chink of air will keep all right. Vines in pots not intended to be forced early, or for planting out, should be placed under cover without delay. An open shed with a north aspect, the pots being protected by straw or other dry material, is suitable, that aspect being most likely to retard growth.

Peaches and Nectarines.—The trees in the earliest forced house should be pruned, if not already done, and then dressed with some approved insecticide. The surface soil should be removed to the depth of 2 or 3 inches and replaced with fresh turfy loam, adding a

tenth of lime rubbish or chalk and a fifteenth part of each of half-inch bones and wood ashes, treading rather firmly, and giving the border a thorough watering. The outside border also should be top-dressed, and if in a thoroughly moist state protect with a covering of litter or bracken, as cold rains or snow reduce the temperature of the soil considerably; but if the border is not wet leave it exposed until it is thoroughly moistened by rains, which are much more beneficial than artificial waterings. The trees in the second early house will have the foliage ripened and falling off, which may be assisted with a light brush-over with a broom. We prefer to prune, dress the trees, and top-dress as soon as the leaves are fallen, as it makes an end of all insects before they have time to find secure winter quarters. In pruning forced trees it is not desirable to cut out much wood; any useless parts having escaped the knife at thinning after the fruit is gathered should be removed, and long shoots may be cut back to a triple bud, making sure that the centre is a wood bud, which is not always the case, and to leave a sufficiency of wood with fruit buds for the insuring of a crop. Shoots of from 8 to 12 inches in length should not be shortened, having usually a few wood buds at the base and one at the extremity, the rest being fruit buds. It is a great mistake, however, to retain much wood, which weakens the trees in flowering, and there is not space for training in the necessary growths for future bearing to secure their thorough exposure to light and air. Afford plenty of air at all times; houses with sliding lights should be closed in very rainy weather. Avoid, however, permitting the borders to become too dry, which is more pernicious than a wet soil at any time.

PLANT HOUSES.

Greenhouse.—Camellias often set many more flower buds than it is good for the plants to expand. Two to a shoot are ample, as more impoverishes the plants, and often when a number are left more buds drop when advanced for unfolding than can be spared. Any superfluous buds should be removed without delay. Plants that are wanted to bloom early and have the buds in a forward state will be assisted to expand in a temperature of 50° to 55°; but if the plants have not set their buds early and are in a forward state placing them in heat will only cause wood growth and the casting off the buds. Azaleas well advanced will soon expand the flowers in moderate heat as advised for Camellias. Cytisus racemosus or fragrans will also come in quickly in a like temperature, the growths being ripened early. Early-flowering Epacris and winter-flowering Heaths are coming in, and should have plenty of light with moderate ventilation; these, with Primulas, early Camellias, Epiphyllums, Heliotropes, Mignonette, and Chrysanthemums, will make a fine display during the dull months. Herbaceous Calceolarias now require to be potted off singly in 3-inch pots. Turfy loam with a fourth of leaf soil or well-decayed manure and a sprinkling of sand form a suitable compost. The plants should be kept near the glass, moist and cool but safe from frost. The earliest Cinerarias will be advanced for flowering. They should have plenty of light and air, with a temperature of about 50° by artificial means to insure their flowering satisfactorily. The second batch of Cinerarias should be moved into the flowering pots, and be kept near the glass, cool and moist but safe from frost.

Lily of the Valley.—Pot-up selected crowns for forcing. Some prefer imported crowns, but we prefer to lift those that have been two years planted in good rich soil in a sheltered situation—an east border. We take all those with plump rounded crowns, the flowering crowns; and those not of a flowering size are at once replanted, the soil being well enriched before doing so. The selected crowns are then potted: they are placed about an inch apart in 6 or 7-inch pots, or pans are sometimes used, and after potting are placed in cold frames and covered with cocoa refuse, the lights being used only to ward off heavy rains and snow. From this they are introduced in batches as required to the forcing house, plunging the pots or pans in a bottom heat of 90°, and covered 2 inches deep with cocoa refuse. This causes them to throw up the flower spikes along with leaves, and when they are a few inches high they may be gradually withdrawn from the bottom heat. Clumps force well later on, and are the best for starting without bottom heat; but up to January bottom heat is necessary, and with that crowns or clumps are alike eligible.

FLOWER GARDEN.

Calceolaria cuttings should be inserted in frames at the back of a low wall or fence with the lights facing north. From 4 to 6 inches of turfy loam with a third of leaf soil or well-decayed manure should be placed in the frames, with a surfacing of sand an inch thick. The cuttings should be taken from the base of the plants—growing points with two joints—cutting them transversely below the lowest joint, and removing the leaves from it, inserting them in rows 3 inches apart, and the same distance between the cuttings. They should be inserted quite up to the leaves and a good watering given. The lights need only be put on by day if the air be dry and the cuttings flag, removing them at night when the weather is mild. If Viola cuttings have not been put in they may be inserted in frames like Calceolarias. A frame will hold a great many, they not being so liable to be

lifted by frost or dragged out of the ground by worms as those in the open ground.

TRADE CATALOGUES RECEIVED.

William Paul & Son, Waltham Cross, Herts.—*Catalogue of Roses, Fruit, and Ornamental Trees.*

Osborn & Sons, Fulham.—*Catalogue of Fruit Trees and Grape Vines.*

Hooper & Co., Covent Garden.—*Catalogue of Bulbs.*

S. Dixon & Co., 34, Moorgate Street, London.—*Catalogue of Dutch Bulbs.*

George Templeton, Prestwick, Ayrshire.—*Descriptive Catalogue of Selected Roses.*

William Thomson & Co., 16, Giles Street, Edinburgh.—*Catalogue of Flower Roots.*

John Moore, Goodhope Nurseries, Warwick.—*Catalogue of Roses, Fruit Trees, Shrubs, and Spring Flowering Plants.*

Harrison & Sons, Leicester.—*Catalogue of Dutch and other Flowering Bulbs.*

William Potten, Sissinghurst, Staplehurst, Kent.—*Catalogue of Roses, Fruit Trees, Conifers, &c.*

James Dickson & Sons, Newton Nurseries, Chester.—*Catalogue of Select Roses.*

André Leroy, à Angers (Maine et Loire), France.—*Supplementary Catalogue of Trees and Plants.*

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense. Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

GERANIUMS (*J. E. Hall*).—We know of no volume that details who raised each variety or who first made it public.

FERNS (*H. R.*).—The fronds we have received are very handsome, being graceful in form with dark green pinnae crimped and serrated; they are remarkable also for their very fine sori, which give to the fronds a somewhat bold appearance. It appears to be a true cross between *Adiantum tenerum* and *A. concinnum*, and is highly worthy of preservation.

ESPALIER TREES (*H. E. Watts*).—Apples and Pears need not be kept separate on espaliers. There is no difference whatever in their cultivation and management, and if you wish to plant them alternately there is no reason why you should not do so.

FERNS DISEASED (*Ivanhoe*).—The stems of your Ferns are much infested with large brown scale. Wash them off with a sponge and soapy water. The pinnae are eaten by a snail, which may be found by searching at night by the aid of a candle.

HENBANE (*Elgie*).—Write to some of the seedsmen who advertise in our columns.

VARIOUS (*C. M. F.*).—The term "vegetables" in horticultural works usually is confined to kitchen garden produce. Melons and Tomatoes are fruits. Ash saplings may appear where Beech underwood has been cleared away, but certainly the saplings are not produced from the Beech. The culture of the Fig tree is stated in our "Garden Manual." The history of the tree is in Phillips's "Companion to the Orchard."

VIOLETS DISEASED (*G. F.*).—We cannot make out what is the matter with your Violets. We have shown the leaves to several gardeners and they have never seen such a thing before. Please to let us know what the effect of the disease (if it is one), and whether any injury arises from it.

FUCHSIA (*B. J.*).—We do not recognise the variety. Hooked sepals such as those you have sent are not usual.

TEBBS' UNIVERSAL STOVE (*H. B., and Others*).—You will find Mr. Tebb's address in our advertising columns. By applying to him you will obtain the information you require.

TULIP CULTURE (*N. C.*).—The bulbs may either be potted, placing three or four in a 5-inch pot, and burying the pots in ashes or cocoa-nut fibre until growth commences, then placing them in a light house or frame; or they may be planted in deep, well-pulverised soil in the open garden, embedding them in silver sand. We do not know the variety you name, but *Gloria Solis* is crimson and yellow, and has larger bulbs than those you describe.

ONIONS (*H. W., Camelford*).—The triple Onion sent appears to be the Welsh Onion, which is not suitable for producing a crop of bulbs. Obtain seed from a reliable source of such sorts as the White Spanish and James' Keeping, and with good cultivation you will have a supply of Onions over a lengthened period.

PRUNING CLIMBING ROSES (*John Wood*).—It is good practice to retain some young growth near the base of the trees, which is liable to become bare and unsightly. Old branches should be cut off when they exhibit a tendency to become barren, but not otherwise. Any wild or crowded growth may be pruned now or at any period of the year.

RAISING GRAPE VINES FROM EYES (*Journal Reader*).—We prefer a 4-inch pot filled with equal parts of broken turves and leaf soil for each eye to root in, taking care to bury it in a little silver sand an inch below the surface. Place the pots in a temperature of 50° the first week in January, raising to 55° in a fortnight, and at the end of the month plunge them in a hotbed with a bottom heat of 90°, and top heat of about 60°. When

the shoots are a few inches high and have four or five leaves lift the pots slightly, and when the shoots are pushing upwards freely and the roots reach the sides of the pots, shift into pots of about double the size and place them in a genial temperature. You may plant them in April or May.

TUBEROUS-ROOTED BEGONIAS (*M. D.*).—Let your seedlings remain undisturbed in the seed pans till March, keeping the soil somewhat dry but not dust-dry through the winter. In March shake them out of the soil and pot them singly in pots an inch or two more in diameter than the bulbs, in rich and very sandy soil, repotting as the plants make progress, which you may accelerate by keeping them in a lively temperature for a time, such as a vinery or stove affords. A high temperature is not, however, really necessary, and when established these answer perfectly well in a greenhouse.

HORSE CHESTNUTS.—"Lilian" asks who buys them.

GLOXINIAS (*Sandgate*).—Six good varieties are the following:—*Erect flowers*.—Candeur, pure white and rose; Skeltoni, crimson, primrose, and lilac; and Pegase, white and scarlet. *Drooping flowers*: Goethe, white and rosy vermillion; Rose d'Amour, white and crimson lake; and Crème et Violet, purple and violet. If you purchase the corns now you might lose some of them during the winter. A safer plan would be to obtain them when you have heat in which to start them into growth immediately on arrival in the spring, any time from February until April. We do not recommend dealers.

INSECT'S EGGS (*L. J. K.*).—The specimens sent are not eggs, but more or less matured individuals of one of the beetle mites, *Damaeus geniculatus* of modern authors. It may be dealt with successfully by several of the methods used for destroying insects under bark, but according to M. Boisduval they do little injury, but rather confer benefit by devouring eggs or young larvae of Acari and Thrips.

WHITE GRAPE SPOTTED (*Reader*).—The minute specks upon your white Grapes are by no means uncommon. We have seen the spot occur on Grapes in the hands of skilful and successful Grape-growers. No doubt the effect is attributable to atmospheric causes, just as the worst form of rust is clearly traceable to cold draughts playing upon the tender cuticle of the berry in the early stages of its growth.

ROSES WITH GREEN EYES (*Idem*).—Green-eyed flowers are the result of an ungenial season. Cold, cutting, north-east winds when the shoots are tender in spring cause green eyes to appear, and we have seen large plants trained to walls so badly affected as not to have one good flower out of some hundreds. During last spring a Marechal Niel afforded a curious illustration of this, all the flowers exposed to the east having green eyes, while those upon some branches trained along a south wall were quite free from this disfigurement.

THE CARDIFF CASTLE VINEYARD (*J. J.*).—The French Vines at Cardiff Castle are proving quite a success. The Vines have grown very freely in this and former years, and they are now thoroughly established. Their fruiting qualities are improving annually. This year the bunches are larger and more numerous than ever. The wine, too, which was made from the first crop is now, as it gains age, of very fair quality. Your Vines should bear a moderate crop in 1879. The varieties chiefly grown at Cardiff—Melier Blanc and Gromier Noir—are better for growing out of doors than any of our house Grapes. Royal Muscadine cannot be depended on to come to perfection every season even against a wall, and Black Hamburgh cannot be classed with outdoor Grapes.

FRUIT TREES FOR EAST ASPECT (*Idem*).—Victoria Plum, Marie Louise, and Soldat Laboureur Pear will succeed well in a partially shaded east aspect.

CUTTING ARBOR-VITES (*Idem*).—April would be a good time to cut your "hedge into shape," giving it a second trimming early in September.

FRUIT CULTURE IN A WINDY SITUATION (*Jas. Chapman*).—Espaliers are preferable to cordons from the greater quantity of fruit they produce, and the best position for the rows is from north to south, so as to ensure as complete an exposure of all the fruit to the sun as possible. The rows should be 6 feet apart, and the trees 20 feet apart in the rows, by which arrangement your plot of ground, 100 feet by 70, will contain thirty trees. Train them after the French style termed *Palmette verrier*, which consists of training each branch outwards and upwards, so that the ends are all on a common level, and equal distribution of vigour is secured. If you have sufficient space outside to plant a thick belt of forest trees for shelter by all means do so, as you will then be enabled to plant pyramids instead of espaliers, and thus obtain a much larger quantity of fruit. The trees should be 10 feet apart, which would give you exactly double the number of trees that you could grow as espaliers. You are right in calling Cox's Orange Pippin one of our best dessert Apples. It is a free bearer, and the tree forms both excellent espaliers and pyramids. Of other dessert kinds take Adams' Pearmain, which has had a heavy crop with us this year, Margil, Kerry Pippin, with Irish Peach for a very early sort, and Scarlet Nonpareil for a very late one. Of kitchen Apples Lord Suffield, Cellini, Keswick Codlin, Warner's King, Hanwell Souring, and the Gooseberry Apple are all good, and of which Keswick Codlin may be termed our best early sort, and Gooseberry our latest. Of Pears take Williams' Bon Chrétien, Fondante d'Automne, Doyenné du Comice, Winter Nelis, Jewess, and Beurré Rance. If you want Plums Early Rivers and Denyer's Victoria are two of the best for cooking, and Green and Purple Gage are an equally excellent pair for dessert.

FLOWERING STOVE PLANTS (*Respect Finem*).—*Poinsettia pulcherrima*, *Asphelandra Roezlii* aurantiaca, *Gesnera cinnabarina*, *refulgens*, and *exoniensis*, *Epiphyllum* in variety, *Eranthemum pulchellum*, and *Euphorbia jacinthiflora* are a few plants affording the colours you require. If you obtain *Lasiandra macrantha floribunda* you will find it flower freely in a small state. The plant you have is a shy bloomer, and the temperature of your house is also 10° too high for it. All the plants named can be grown and flowered in a dwarf state. *Aloe frutescens* flowers in a greenhouse after the plant has been well grown and afterwards kept dry at the roots for a month or two.

MANAGEMENT OF BULBS (*E. F.*).—If the soil is moist when the bulbs are potted, and the pots are covered at once 3 or 4 inches deep with moist ashes or cocoa-nut fibre, no water is necessary until the pots are removed; but if the soil is at all dry give one thorough watering so as to moisten every particle of it before burying the pots. The other plants you name are best wintered in a light cold frame, removing the lights during fine weather, and admitting air freely except during severe frost. The dark outhouse would ruin such plants, and they would not keep well in the conservatory.

CUCUMBERS UNDER GLASS (*W. H. G., Oldham*).—Our "Garden Manual" contains full directions, 1s. 9d. post free.

VINES IN GREENHOUSE (J. C. N.).—We think you may succeed in ripening Black Hamburgh Grapes in your greenhouse, but we doubt if you will succeed equally well with Peaches on the back wall. You might try, however, a tree of Royal George. A minimum temperature in winter of 35° to 40° will be ample for preserving Geraniums and similar plants, and more heat would be injurious to the Vines and Peach trees.

COARSE WEEDS (R. Wulhen).—You will have great difficulty in eradicating the weeds. The only remedies are draining the soil and cutting down the weeds as soon as they appear.

CHERRIES (Llanberis).—If you will inform us in what form you purpose growing the Cherry trees, and for what purpose the fruit is required, whether for dessert or kitchen use or both, we will endeavour to aid you. You ask for three of the best Morellos. There is only one Morello, or two if we include Belle Magnifique, which is also known as Morello de Charnex.

MOSS ON TOMBSTONES (J. S.).—Mr. West, Northlands, Salisbury, states that ammoniacal liquor or gas water will kill all moss or any vegetation on tombstones. The liquor is readily obtainable at gasworks at a trifling cost. After the ammonia has been applied, and the stone has become quite dry, scrub it with a rough broom to dislodge the moss. Mr. West also finds the gas water an excellent application for killing weeds and moss on gravel walks, and for imparting to the gravel a new and fresh appearance.

FORCING VINES IN POTS (L. E. G.).—Though the Black Muscat forces well, also Muscat of Alexandria, early in January is quite soon enough to commence forcing those kinds, as they do not set well in the dull winter months, nor ripen perfectly without considerable sun heat. Black Hamburgh and Muscat of Alexandria are the two best Grapes in existence, and succeed admirably in the same house, they forming a good succession. If you start forcing early in November we advise Black Hamburgh, Golden Hamburgh, Foster's Seedling, and White Frontignan; say twelve of the Black Hamburgh, two each of Golden Hamburgh and Foster's Seedling, and four of White Frontignan, which last is rich in Muscat flavour.

CONSERVATORY ARRANGEMENT (Mrs. Hirst).—The borders at the sides are much too narrow for the growth of plants, though they will answer very well for climbers, and you might have a shelf the width of the border all round the house except the doorway, which would be available for flowering plants in pots. The space at the ends of the centre bed with fountain in the centre may be planted with Camellias in a prepared border; but in so narrow a house we should not have any plants planted out except the climbers, but would have the flowering and other decorative plants in pots or tubs as may be required. In the case of borders for planting out, they require to be wide to accommodate such plants as Dracenas, Tree Ferns, &c., which have a considerable spread of head; therefore we should keep to the pot system, which will admit of your having greater variety and succession of flowering plants, some of the plants being grown in other structures and removed to the conservatory when in flower.

ERRATA.—Messrs. Veitch's new Cattleya described on page 294 as *Mastersoniana*, should have been "*Mastersoniana*," and the white *Anthurium* "*A. Scherzerianum album*."

NAMES OF FRUITS (Roseth).—Lewis's Incomparable. (*L. R. L.*).—1, Louise Bonne of Jersey; 2, Paradis d'Automne; 3, Baronne de Mello. (*A. Poirel*).—1, Hawthornden; 2, Nonesuch; 3, Cellini. (*B.*).—1, Golden Winter Pearmain; 2, not known; 3, Golden Reineette; 4, Winter Peach. (*E. H. A.*).—1, Doyenné Boussoch; 2, not known; 3, Reineette de Canada; 4, Tower of Glamis; 5, Nouveau Poiteau; 6, Beurre Diel. (*F. J.*).—1, Nelson Codlin; 2, Cellini; 3, Pott's Seedling; 4, Gloria Mundi. Pears.—1, Beurre Diel; 2, Louise Bonne of Jersey. (*James Wood*).—1, Blenheim Pippin; 2, London Pippin; 3, Pearson's Plate. There were no numbers on the others. The Peach is undoubtedly Salway. (*R. Troop*).—1, Marie Louise; 2, Louise Bonne of Jersey. (*J. Juggelen*).—1, Reineette de Canada; 2, Waltham Abbey Seedling; 3, Cox's Orange Pippin; 4, Hollandbury. The small Pear is Orange Tulipée. (*H. Gadd*).—1, Beauty of Kent; 2, Hall Door; 3, Tower of Glamis; 4, Formosa Pippin; 5, Alfriston; 6, Mère de Ménage. (*E. C.*).—The Pear may be Zephirin Grégoire, but the specimens are too imperfect for us to determine with certainty. (*C. J. N., Kilkoil*).—Beurre Capiaumont. It is not unusual for Pears to bloom and bear fruit a second time the same season. (*R. W.*).—1, Blenheim; 5, Golden Pippin; 7, London Pippin; 9, Royal Russet; 10, Hawthornden; 12, Sturmer Pippin.

NAMES OF PLANTS (T. O. G.).—We think it is *Santolina incana*, but the spray was crushed in transit. (*Amateur*).—*Colchicum autumnale* flore pleno. The Roses will stand in the winter in a cold frame. (*Kappa*).—*Tussilago japonica* fol. variegata. (*F. A. Fawkes*).—Caper Spurge (*Euphorbia Lathyris*). (*Young Gardner*).—1, Aster sp.; 2, *A. Tradescanti* (?); 3, *Sedum Sieboldii*. We do not name florists' flowers. (*Bathgatensta*).—You should send Ferns in fruit. 7 is *Cystopteris fragilis*. (*New Subscriber*).—1, *Limnantes Douglasii*; 2, *Aster Amellus*; 3 and 4, *A. Novae-angliae*; 5, *Coronilla Emerus*; 6, *Hypericum grandifolium*? (*Ramatho*).—Madder Fern is *Asplenium umbrosum*. The only general synopsis of Ferns is Hooker and Baker's, now in its second edition, published by Hardwicke. (*E. H.*).—2, *Pteris quadriaurita* var. *argyrea*; 3, *P. cretica albo-lineata*; 4, *Lomaria discolor*; 5, *Scopolopendrium vulgare*. (*M. J. Carpenter*).—*Pellaea rotundifolia*; *Aspidium (Cyrtomium) falcatum*. (*E. W.*).—The Fern is *Polypodium cambricum*; the Begonia, *Evasiana*. We cannot with certainty name the Fuchsia, there are so many so nearly alike. It resembles *Avalanche*. (*W. W.*).—*Pyrethrum uliginosum*. (*F. C.*).—*Cotoneaster microphylla*. Sow the berries in pans, or graft it on the White Thorn.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

HORNED EWES AND LAMBS.

(Continued from page 303.)

As we have before stated, there is less risk and loss at lambing time with this stock of either ewes or lambs in consequence of the lambs falling in October and November when the weather is comparatively mild. When lambing takes place in December and January it is necessary to resort to the lambing yard and

shed, whereas in the former case a fold at night upon some dry and sheltered pasture is all that is requisite. Without the home fold the shepherd would find it impossible to give that attention at night if the ewes were allowed to roam at large in the pastures, as we find that ewes when about to lamb usually draw away from the rest of the flock, and in case of a dark night the shepherd would find it difficult to attend them individually when allowed to lie over a whole field. In the fold the shepherd, even in the darkest night, when provided with a lantern will be able to notice those requiring his assistance, and the young lambs when they fall cannot stray away from the mother and be lost. Small pens with a little straw at bottom are made a hurdle square to place the ewes and their lambs in, and this is especially necessary with twins, and when perhaps ten or twenty ewes may lamb during one night. As fast as the lambs become strong enough the ram lambs should be castrated when they are about three weeks old, and twin or weakly lambs at about a month old.

When the lambs are old enough to commence feeding it is requisite, not only for their own sake but also for the advantage of the ewes, that their food should be of the best, so that the ewes should be relieved to some extent of the heavy call made upon them, and that they may begin to lay on flesh at the earliest period, with the view of their being made fit for the butcher at the time when the lambs go to market. In order to effect this desirable object the ewes must also be fed in the best possible manner; and when the change is to be made from pasture to root-feeding on the arable land it is best to have troughs in the pasture, so that the ewes may receive a small quantity of cut roots and such food as they will be required to eat when they go on the arable land. They will then become somewhat accustomed to root-feeding, otherwise the sudden change from grass to root-feeding interferes with the condition of the ewes, and often diminishes the milk, which checks the lambs. Before commencing root-feeding it is a good plan to have a portion of roots, whether of turnips, Swedes, or carrots, pulled and prepared for the cutter about a fortnight before they are required for use. In trough-feeding this will give time for the work of preparing to be kept well in advance of the sheep, because frost, wet weather, or snow often prevents the parties engaged in continuing the work, and thus stops the system of feeding, which when once began cannot be discontinued without serious loss to both ewes and lambs. We recommend that the lambs should receive cut roots as well as the ewes. It is, however, a practice with some farmers to allow the lambs to run over the turnip greens in advance of the ewes; but we object to this system, and prefer a fold in advance of the ewes. To feed them without anything but trough food the lambs will not only by this plan of feeding be more healthy and avoid the scour often produced by frosted turnip greens, but they will prove of better quality when fit for sale.

We do not propose here to describe the method of feeding the lambs, it having been fully explained in all its details in an article in this Journal upon the management of forward down lambs in vol. xxxiv., page 187. We prefer in the interest of the home farm to state our plan of holding over or the purchase of horned ewes in the spring of the year in preference to purchasing the ewes in lamb in the autumn, and carried out by us for a long series of years, which we can with confidence recommend, particularly where only a few ewes of this breed are kept as ornamental objects on the park and pasture lands. If we have a flock of considerable extent of ewes purchased in the autumn a portion of these will usually drop their lambs too late to feed the ewes fat whilst suckling their lambs. We therefore put all the ewes which lamb after the 20th of November upon moderate keep, say hay and roots without cake, but let the lambs run in advance and be fed in the best possible manner. These ewes in the spring will consequently be found in only good useful stock condition, and after their lambs are sold they are treated for the rest of the summer months as stock animals. If we require to

increase their numbers we purchase poor ewes and add to them generally at Guildford or Chertsey fairs in Surrey, and as a profitable farming matter it is found best to keep a stock flock in summer and a fatting flock in the winter. The plan we are describing is admirably adapted for this purpose, because the ewes only receive short keep, and are close folded at night, except in extremely hot weather, when they are folded at daytime from ten o'clock in the morning to four o'clock in the afternoon, otherwise the ewes to avoid the teasing of flies, from which the ewes suffer very much, will run into hedges and ditches during the heat of the day, and there leave their manure. It must be remembered that this stock will not fatten readily in the summer, but when they are kept in numbers on bare keep they increase in value as they approach the time of lambing, and if carefully managed are far more valuable than any which can be purchased at the autumn fairs. This is not only because they become acclimatised to the district in which they are summered, but because we have the opportunity of choosing the rams, upon which the value and quality of the lambs greatly depend; at the same time we can choose our own season at which the lambs shall fall, and put on to fattening food at once any ewes which do not prove in lamb after a certain date.

Our practice is to run the tup with the ewes the first week in May, one tup being sufficient for fifty ewes. Well-bred Hampshire downs with close short wool should be selected, in order that the lambs, more especially in the case of twins, which require to be longer kept, may wear a close firm coat. It is a generally accepted fact that loose hollow wool injures the sale of fat lambs in the live market. The lambs also begotten by a Hampshire Down ram possess a much larger proportion of lean meat, and will make greater weight at a given age than those reared from the Southdown cross. In proof of this we have frequently seen sucking lambs at Easter, being at that time about twenty-two or three weeks old, the twins weighing 20 lbs. per quarter, and the singles up to 23 lbs. per quarter, the ewes being at the same time sold to the butcher at heavy weights. The rams before being turned with the ewes should be shorn and kept in a dry open shed about a fortnight or three weeks beforehand. If placed with the ewes for service in their wool they are lazy and inactive. The plan of feeding the ewes must also be considered, for it is of consequence that their food at this particular juncture should be generous. We have found nothing better than a fold of trifolium cut up and put in racks, and also cut mangolds or Swedes in the troughs, with a run in a dry sheltered pasture for a few hours at daytime. If, however, circumstances should arise, such as cold wet weather, to delay the season of the ewes, they may be advanced by giving them half a pound of cracked beans each per day.

After the ewes are ascertained to be in lamb the rams should be removed, and from this time the ewes should be kept in store condition, receiving only bare keeping with a constant change, but especially should they lie upon the cultivated land at night time. They may then be pastured upon meadows at daytime, which otherwise may induce the rot—that is, the fluke worm in the liver. In some wet seasons the entozoa, or germ of the fluke found in the grass, may be taken into the system by the animals whilst grazing, and if they had no change of food and dry lying at night their livers would become diseased with fatal effects to the ewes. Our own experience proves this to us conclusively, for during more than twenty years of feeding unsafe meadow land we never had a case of rottenness. We can only attribute our success to the change of food and the night layer on the arable land with rock salt always at hand, this being the great antidote. Under these circumstances, although the entozoa may enter the system, yet it fails in producing the dreaded fluke in consequence of the quality and condition of the food, &c., not being congenial to the habits and requirements of this parasite.

WORK ON THE HOME FARM.

Horse Labour has now ceased connected with tillage work for all future crops, and will not be resumed until the fallow ploughing takes place, after the sowing of wheat is completed. The horses are, however, now fully engaged in drawing and laying out dung upon the clover leas, and also in ploughing and pressing for wheat. When there is much work in arrear, however, it may be advisable to hire the combined steam plough and presser. This turns and presses five furrows simultaneously, and soon alters the state of matters, and we have just seen this work going on with capital effect. There is work done in one day which would require eight horses, or ten horses, or more upon some soils. The advantage to be derived is not so much a question of cost as of the time saved and the forwarding of work previously in arrear.

Some horses will be engaged in lifting potatoes and preparing the land afterwards for either wheat or barley, for upon good loamy land wheat always succeeds well, and upon sandy or light soils barley does well. If the land is laid up for the winter after each of these corn crops the broad clover is more sure to take well, and better than after any other preparation. At the present time the odd horses will be engaged in carting the mangold crop to heap, and also carrots or Swedes as may be required. In con-

nection with this subject we have come across a memorandum wherein we find that in the year 1862 we were at this period pulling and clearing off a turnip crop from the potato land (before digging the potatoes), which was carted away and stacked in fields ready to be used for feeding ewes and lambs upon the wheat stubbles. The greens were used daily for cattle, and for several weeks proved very useful food for store cattle, pigs, &c. Our plan of storing the turnips is different from that of mangold, because we only place them between hurdles and thatch the top with straw to keep them dry; and as they are not required to be kept any great length of time they come out well for use, especially when the greens are not cut off too close to the bulbs.

Hand Labour will still be various, for if threshing of corn is going on this will employ some hands. Also spreading dung will be continued until finished. Hedge-trimming will have been finished; if not, it should be completed immediately. The cleaning-out of ditches and watercourses should be done before the heaviest rains set in, so that there may be no impediment should the rainfall approach to flooding. This will also be necessary upon the home farm where draining has been done, so as to give and keep a proper outfall to the water into the watercourses or brooks as the case may be. We have meadow lands which have been drained with outfalls into the brook, and we find that in peaty soils there are red ferruginous substances which are apt to accumulate in the drains, in which case we introduce a strong iron probe and swab for clearing away these obstructions, which if allowed to remain soon block the tiles, which must be taken up and replaced. We use the probe always in the autumn, and it is made of jointed stout iron rods, so that it may be increased to a great length if required. All cattle intended for the Christmas shambles ought now to be in the boxes or stalls, where they may be provided with the best of food. Grass is still good for dairy cows and store cattle but not for fatting bullocks. Shepherds will now be busy with not only the fatting sheep eating-off root crops, but also in attendance upon the breeding ewes of different sorts. The earliest lambing stock will now be dropping their lambs and must be attended to accordingly. The later lambing varieties of sheep will require a constant change of food, and if possible without root-feeding. Particular attention should be paid to ewes that are lambing, for when in high condition they are very likely to suffer from inflammation of the udder, in which case the old plan was to bleed from the udder vein, but we always bleed from the neck. We recollect an instance when we had a fresh shepherd upon one of our farms, that we had three ewes with seriously inflamed udders. Our new shepherd said they were sure to die, and that he had never seen such cases cured. We, however, to teach him his work, bled the ewes freely from the neck vein with a small lancet, which we always use for the purpose. They bled until they dropped down fainting. This, however, completely altered the deep red colour of the inflamed udders to the healthy colour. We then applied sugar-of-lead ointment, which answered the purpose on two of the udders; the third, however, was proceeding to mortification rapidly. We then applied the verdigris ointment, a sure remedy and preventive of mortification. All three of the ewes lived, and two regained their milk, but one lost the udder entirely.

THE CRYSTAL PALACE POULTRY SCHEDULE.

THIS important schedule, which has become quite the size of a pamphlet, demands special notice. The additions to it this year seem to be both large and important. In some cases particular breeds are somewhat over-favoured in the great subdivision of their classes; but this, we understand, is owing to the special private generosity of their admirers. If the fanciers of all breeds were equally liberal and enthusiastic equal justice might be meted out to all.

We will first look for any general novel features of the schedule, and then come to particular additions to it.

In rule 4 we see a concession to the demands of many exhibitors, made, we fancy, for the first time formally—viz., "Each entry for poultry must be packed in a separate hamper, except when two or more entries are made in the same class, when they may be sent in the same package, provided they are properly divided and separately labelled." This we know by experience is a great convenience as well as economical.

In rule 5 we learn that the old plan is reverted to of birds being delivered at the Palace on a Saturday—viz., November 9th. We much regret this. In much experience as exhibitors at the Crystal Palace we have suffered twice from any mistakes. These were both serious, and both occurred from Sunday or Monday penning of birds which had arrived on Saturday. We venture to impress upon those who superintend the penning that advantage should not be taken of the intervening Sunday to defer the work till the last moment.

Rule 6 is chiefly new and an admirable one, we will therefore give it *in extenso*:—"The Judges appointed to award the prizes will be instructed to disqualify and mark any pen which they may detect to have been tampered or improperly dealt with, and no appeal from their decision will be entertained upon any ground

whatever. Any exhibitor detected in fraudulent practices shall forfeit all or any prizes or cups that may have been awarded to him, and the entry fees in such cases will not be returned. The Judges will also be empowered to withhold a prize or prizes when, in their opinion, the specimens are not of sufficient merit. When a cup is awarded the money prize will be withheld, unless otherwise specified. All protests against awards must be lodged with the Secretary before 12 A.M. on the 12th of November, and must be accompanied by a deposit of £1 ls. Such protests will be submitted to the Judge or Judges for consideration, and they will be requested to state if they consider such protest is frivolous or made without due ground, in which case the deposit will be forfeited."

We are glad thus to see the wide and general influence which the honest efforts of the Poultry Club have had towards getting the rule adopted of all prizes being forfeited by any exhibitor detected in any dishonourable practice. The scandal cannot again occur of a person winning cups in several classes, and being disqualified for winning in another. We are sorry to learn that the authorities expect considerable diminution of their entries, especially in the Pigeon classes, in consequence of their praiseworthy boldness in adopting this rule. We can only say that their resolve, in spite of their fears, speaks better for them than for exhibitors. We mention the fact simply because we are sure that many fanciers will be glad (as we shall ourselves endeavour to do) to increase their entries, and with the object of preventing any loss from the discomfiture of the trimmers.

The classes for poultry have grown to the amazing number of 132, and those for Pigeons to 112. There are forty-three cups for poultry and forty for Pigeons. Dorkings have twelve classes as before. We fancy there is a printer's error, and that cup No. 4 should be for Silver-Grey Dorking cock or hen, not cock alone. Cochins have sixteen classes, Black cocks and hens being this year shown separately and not in pairs, and a class being added for pairs of Cuckoos. Brahmans twelve classes. A new class is added for pairs of hens or pullets, price not to exceed £5 5s. We consider this a good move, and should like to see it adopted for Dorkings as well. Spanish, Houdans, Crèves, and Hamburgs have the same classes as before. Five extra classes are allotted to Game; each of the four varieties now have their four classes, and there is a five-guinea Selling class for pairs of any variety. Sultans have a class for the first time at the Palace. Why Silkies are denied one we cannot understand. An extra Bantam Selling class is provided for pairs of hens, and a Selling class for Duck and drake not exceeding £3 in value.

In Pigeons Pouters still have ten classes; Carriers no less than seventeen! A champion class is new, and there are four classes for Blues—viz., adults and young birds of both sexes; Dragons twenty classes; Barbs six with three cups, two of them of five guineas each; Jacobins have six classes, Blacks being separated from Any other variety; Owls have an immense extension of classes—viz., eleven and four cups; Turbits have two classes for young birds in lieu of one, Blues and Silvers being very properly separated from Any other colour; Magpies have three classes; in Runts the sexes are divided; Flying Tumblers have two classes (one extra), Antwerps five (one extra), and cocks and hens are divided in the single bird Selling classes; this is a great improvement. We are not very partial to Selling classes, believing that they are often the media through which bad birds are palmed off on the ignorant and unwary. It is something, however, that exhibitors should be obliged to name the sex of their birds and be responsible for it.

The entries for this grand Show are stated to close on October 19th, but we hope that, as in former years, a week's law will be given for entering, considering the late date at which the schedules were issued.—C.

DIPTON POULTRY AND PIGEON SHOW.

THE third annual Exhibition was held on the 12th inst. in a large marquee. The district of this Show is in the centre of the North Durham coal field, and the Committee are for the most part miners. The marquee was placed in a field kindly granted for the occasion by the Treasurer, where a most extensive view of the vales of the Derwent (famous as running through the lands claimed as belonging to the Countess of Derwentwater), and prettier scenery is scarcely to be found in England. The following are the awards:—

POULTRY.—COCHINS.—1, G. Latimer. 2, W. D. Rowell. DORKINGS.—2, W. Watson. SPANISH.—1, J. Gales. *etc.* T. Gibson. BRAHMAS.—1, R. Lewins. 2, G. Proudlock. HAMBURGS.—Golden-spangled.—1, W. Bearpark. 2, P. Sharp. Golden-pencilled.—1, A. & J. Bell. 2, C. Close. Silver-spangled.—1 and *etc.* P. Sharp. 2, C. Close. Silver-pencilled.—1 and 2, G. Latimer. *etc.* J. W. Hodgson. ANY OTHER VARIETY.—1, R. Wallace. 2, G. Nicholl. *etc.* G. Eltringham. G. Nicholl. SELLING CLASS.—1, A. & J. Bell. 2, J. Burnip. *etc.* G. Dyson. GAME.—Black-breasted and other Reds.—1, P. Sharp. 2, R. Miller. *etc.* J. Condon. G. Walton. Any other colour.—1 and 2, Ridley & Waggett. *etc.* G. Walton. Any variety.—Cock.—1, Ridley & Waggett. 2, A. & J. Bell. ORIGINAL GAME COCK.—1, J. Brown. 2, G. S. Nellist. BANTAMS.—Black-breasted and other Reds.—1, J. Jones. 2, Ridley & Waggett. *etc.* R. Miller. Any other colour.—1, Ridley & Waggett. 2, Miss C. Charlton. 3, H. W. & H. King. *etc.* R. Wallace. Miss C. Charlton. BANTAM.—Cocks.—1, Ridley & Waggett. Ducks.—1, R. Usher. 2, W. Bearpark. PIGEONS.—DRAGONS.—1, R. Armstrong. 2, W. C. Moody. POUTERS.—1

and 2, J. Dye. TUMBLERS.—1, E. Bland. 2 and *etc.* R. & J. Anderson. TUMBLERS.—1, Brown & Hastie. 2, F. Wilson. TUMBLERS.—1, R. & J. Anderson. 2 and *etc.* E. Bland. TUMBLERS.—1, J. Dye. 2, G. Carr. *etc.* Brown & Hastie. BARBS.—1, T. Handy. 2, P. Wilson. *etc.* G. S. Nellist. TURBITS.—1 and 2, J. Dye. *etc.* W. F. Clark. OWLS.—English.—1, J. Young. *etc.* G. Heppell. P. Wilson. R. & J. Anderson. MAGPIES OR NUNS.—1, W. Allison. 2, S. & J. Linsley. *etc.* E. Barker. P. Wilson. JACOBINS.—1, G. Henderson. 2, S. & J. Linsley. *etc.* P. Wilson. CARRIERS.—1 and 2, J. Dye. ANTWERPS.—1, R. Armstrong. 2, R. Walker. ANY OTHER VARIETY.—1, S. & J. Linsley. 2, G. S. Nellist.

JUDGES.—Poultry: Mr. Robert Shield. Pigeons: Mr. W. B. Van Haansbergen, Woodlands Hall.

PIGEONS AT THE AGRICULTURAL HALL.

THIS was the first year that Pigeons were included in the schedule, and the classification was not very extended, notwithstanding eight hundred birds were shown.

Pouters had four classes. The cup went to a very fine Blue cock first in his class. An immense Black cock was second, still in the moult. In young cocks another very good Blue came in first. In adult hens a most beautiful White was first. In young hens first was a pretty Blue, second a very nice Yellow. Carriers had a champion class with only two entries. Mr. Baker's famous Black cock won. The other entry—a good hen—was quite out of condition. In the general class for cocks Mr. Hedley was first with a splendid Black; second and third were also Blacks. Hens.—First a Dun, very fine in head properties; second, another Dun in many points quite equal to first; third a Black out of condition. Cocks any other colour.—First and third Blue; second a White. Hens any other colour.—First, a well-shaped Blue; second a Silver. There were three classes for birds bred in 1878. We saw many most promising among them. The Black cup cock deservedly had his place. Dragons had thirteen classes. First came a champion class with five entries. One of the best Blues known won here. We could not do more than note what appeared to us the very best birds in the whole collection. They were the first Silver cock, a wonderful bird; the first Grizzle cock; and the second young Blue cock. Tumblers had six classes. The first Almond cock was very pretty in carriage; the first hen beautifully spangled. In Any other variety Shortfaced a perfect little Agate won. Second was a good Red Mottle. Longfaced Tumblers had two classes. A Blue Beard and a Black Mottle were respectively first. Barbs had but one class, and consequently few entries, though good. First a fine Black, and second a grand Red. Jacobins were throughout very good. In Red or Yellow cocks the first Yellow was splendid, and the second Red very good. We much admired, too, the first Red hen. Any other colour.—First a Black, with hood not close enough to please us. Fantails.—White. All the three winners were of the same type—largeish birds with fine flat tails. Among the unnoticed was the little cup hen at both Palaces last year (No. 1467, Cresswell), showing more motion and carriage to our fancy than any bird in the class. Any other colour.—The winners, all Blues, were but middling. When Blues have fair tails they seem generally to carry them horizontally over their heads. Nuns were apparently good, first and second being Blacks, third a Red. Trumpeters.—First a fine Mottle, and second a good Black. Owls.—The champion class came first with three entries. A White African won the first honour, and another bird of the same variety was second to it. The first Silver cock and the first White African were both of their kinds admirable specimens. Turbits.—Blue or Silver. First a good Blue cock which we have often seen before. Second a Blue Shell very foul in flights, and with shell irregular from the moult, but capital in breadth of skull and thickness of beak. Third, a down-faced little Blue hen. Any other variety.—First, Mr. Burnell's ubiquitous little Yellow. Second a Yellow, better in colour but very inferior in head. Third a good Red. Birds bred in 1878 were a wonderful class of twenty-three. Many deserved notice which, beyond the prize cards, they did not get while we were at the Show, though by the prize list they seem to have been awarded to them. First was a Blue good all round, second a Black good in colour and clean in thigh—great merits; still we should hesitate in a good class to give a prize to such a mousy-faced Turbit. Third another Blue, which we thought might well have succumbed to a Silver (Burnell) or a Black (Cresswell). Magpies.—First and third beautiful Blacks. Second Red. Runts.—First a gigantic Silver far ahead of the rest, second a Blue, and third a Silver. Antwerps.—Shortfaced had but one class, and that a poor one. The first a Red Chequer seemed to us the only first-rate bird in the class. Homers were numerous, as they are everywhere now. The wonderful performer which flew from Rome to Brussels was exhibited (not for competition) by Mr. Tegetmeier. Any other variety was not a large class. The birds were shown in pairs. We admired the second Blue Priests very much.

BIRMINGHAM CATTLE AND POULTRY SHOW.—The thirtieth annual prize list as revised by the Council is stated to be the most liberal in the amount of premiums offered that has yet been issued, and in the cattle section it is open to an exhibitor who is also the breeder of the best animal to win a larger amount in cash and plate

than ever was offered at the shows of this or any other society—viz., the best of the breed, £100; the Gibbs prize, £105; the Elkington prize, £105; the President's prize, £25. The Elkington trophy is a handsome cup, which has to be won twice successively or any three years by the same exhibitor; but all the other prizes are given outright. The different breeds do not, as is the case at many other shows, compete against each other except for the special prizes, and this is an arrangement of which exhibitors approve. Exhibitors, moreover, are not required to become members of the Society in order to compete, but are only charged a moderate entrance fee on each entry. In regard to sheep, it is possible for the best pen to win as much as £75, and here also in competition the various breeds are kept distinct. Bingley Hall Christmas Exhibition has now become the recognised mart with breeders for young store pigs of all breeds, as the exhibits of the several owners in the classes for fat pigs show what the sort can do, and we are informed that from two to three hundred breeding pigs from three to six months old regularly change hands on these occasions. The poultry schedule is on the same liberal scale which has characterised it for thirty years. As fast as new breeds come up and prove by their merit or numbers that they are worthy of recognition, new classes are added, but rarely are any struck out. It is found that from 2000 to 2500 pens are as many as can fairly be accommodated, and the entrance fee has, in consequence, been raised from time to time to keep the department within reasonable bounds. Mr. John B. Lythall is still the Secretary, from whom every information may be obtained.

VARIETIES.

We are frequently being asked questions about Pekin or Cochinchina Bantams, &c., where to procure them. Our general answer is that they are hardly procurable for money, unless the purchaser is prepared to claim the one or two pairs occasionally shown at their catalogue price of £100 or more. About two years ago we heard from an enthusiastic fancier that he had an agent with exceptional opportunities and great knowledge of China scouring the country for them. We have lately heard that he has entirely failed to procure any, and believe them no longer to exist in the country. Our advice, in consequence, to the one or two fortunate possessors of them, is to cross them with Nankins and back again with the original stock before the race in this country dies out entirely.

— MESSRS. SUTTONS' Royal Berkshire Root Show will take place in the new range of warehouses at Reading on the 23rd prox. Special prizes are offered for sewage-grown roots, which will make the other classes more open. The new feature of the Show is the grand prize, a gold cup value £20, for the best three dozen roots of Suttons' improved varieties of mangold, which it is expected will bring together such a collection of roots the like of which has never been seen.

— AN Edinburgh correspondent informs us that the long term of dry mild weather is proving valuable for lifting the Potato crop. The farmers are very busy among them, and a few days more will make all safe. The crop is a very fine one both in quantity and quality, with less disease than has been seen for many years, consequently prices are very moderate.

THE STEWARTON VERSUS THE LARGE SKEP SYSTEM.

"STRONG men, strong horses, and strong stocks of bees recommend themselves," writes Mr. Pettigrew, and we add, in exact proportion as their respective strength is wisely applied.

The Stewarton colony is peopled with two prime swarms, the big straw skep with one, consequently the former has double the strength at the start to recommend it; but what about the application?

Mr. Pettigrew teaches as his system the avoidance of all hives of wood, particularly bar-framers, supers, and super honey, Italian bees, artificial comb foundation, the extractor—in short, everything that savours of improvement by such appliances, and generally to revert back to the crudest of all systems—the straw skep one, and emphasises his partiality therefor by insisting on an enlarged edition being adopted everywhere, peopled with the old black bees "bred in-and-in for ages!"

The big skep, 18 or 20 inches by 12, is to be peopled as I have said with a single prime swarm, the combs of which are to be rendered fixtures by five or six cross sticks having previously been run through it. Towards the end of the season the bees are to be expelled by driving, the hive's contents converted into run honey, two or three lots of such driven bees to be united in an empty hive and fed on sugar syrup as a stock for the ensuing season. Such is your correspondent's system, and as he has promised to point out the "faulty features" of the Stewarton prior to having mastered its first principles, I may be excused describing for the benefit of the general reader a few of the faulty features of the big skep as compared with the working of the Stewarton system.

First as to size. In vast heath districts and favourable seasons the size of the common skep might be beneficially increased; but, unfortunately, all districts are not alike nor seasons good, hence a fixed huge size for all is a mistake. In poor districts, or in the cold early spring months when the population is reduced to the minimum, they cut as awkward a figure as does the little Pat in his father's breeches, although we cannot withhold wishing good luck to both to grow to fill them. The Stewarton, on the other hand, is built in sections, is a small hive in spring; the precious heat is much more economically raised and better concentrated, and breeding in consequence goes on more rapidly, space being afforded proportionately to the season, district, or wants of each particular colony for either breeding or storing, and from every comb being moveable stocks can readily be strengthened by interchange of brood or store, and the expense of autumnal feeding is in a great measure saved.

The second faulty feature of the straw skep system we will look at is the mixed and impure nature of its pressed or run contents. Such honey is composed of a mixture of, among others, first the surplus sugar syrup of the previous spring and autumn feeding, the gleanings of the fruit blossoms, the sycamore tree, the bean field, the pure nectar of the white clover, the greenish-tinted lime, the yellow bindweed, and the dark exudation of the purple heather, all crushed up together into one grand blend, piquantly flavoured with the varied and acrid pollens of many a flower and plant; bad enough the idea, even though we exempt the white grubs of the brood cells so frequently seen floating in the precious mess. What would be thought of the gardener who would send the best fruits of the season served up on his master's table crushed in this hotch-potch style, or the sugar refiner who would send to market his "low yellows" and purest "crystals" jumbled together? The skepist does it. On the other hand the shallow supers of the Stewarton hive afford facilities for the combined large body of bees to store rapidly and distinct the various honeys, at the same time ensuring a pure sample and fine finish. In our district, for instance, in keeping with the favourable weather, while the staples are in bloom the first or lowest super has generally a greyish tint from the bean, then follow two or three finest pure white clover, our main staple, with one or two from the limes to succeed, the uncompleted usually being part bindweed and heather honey, the last only available after a long flight in fine settled weather, all without a speck of pollen, the collectors of which (the queen and nurses) are kept shut within the breeding department by the central slides of the upper breeding box being securely closed, the honey-gatherers congregating on the end honeycombs, only admitted to the supers through these outer slides overhead being alone drawn. While disparaging super comb Mr. Pettigrew overlooks the fact that in so doing he depreciates the source from whence the purest and finest run honey can be drawn. The magnificent samples exhibited at the Caledonian Apian and Entomological Society's shows at Dumfries and Glasgow this last season were so close that a very few motes in a highly flavoured glass were sufficient to cast it, the Judges thereby teaching a useful lesson to the cottager of scrupulous cleanliness for the time to come, and on inquiring of the successful competitors from whence they drew their supply was answered "Super, of course."

The third and last faulty feature of the skep system to which for the present I shall allude is the destruction of the maturing autumnal brood, the very life blood of the stock, which is unavoidable where bees are driven from fixed combs sufficiently early in autumn to admit of their fabricating others in an empty skep before severe weather sets in, except they be placed in frames so that they can be kept constantly covered by the workers till hatched. Mr. Pettigrew does not advocate the brimstone pit, but teaches in his book how bees can be so destroyed, terms those who save and think it inhuman to destroy our little favourites "sentimentalists," and adds, page 178, "There is nothing in the destruction of the lives of bees more cruel or inhuman than there is in the destruction of the lives of cattle, sheep, or fowls." Is this sound reasoning? Are the cases at all analogous? We cannot consume the flesh of any of these creatures without first depriving them of life. It is not so with the bee. We framists can cut to the last cell, or better still, with the extractor drain to the last drop of honey it contains, without breaking an egg, hurting the weakest larvæ, or even damaging a cell wall. To take the useful lives of even the tiniest creatures unnecessarily we hold to be nothing less than wanton cruelty.

I have had already occasion to advert to the manifest unfairness on the part of Mr. Pettigrew drawing comparisons of harvest results between different districts, and of pitting against net weight pure super honey and gross weight of big straw breeding skeps, and now regret to find statements still more reprehensible. At page 216 of this Journal he says: "In 1868 our Renfrewshire friend had glorious results in supers from a Stewarton hive. The results the same year from a straw hive in an adjoining county (Lanark) were equally good—viz., 328 lbs. gross." On referring to page 78 of Mr. Pettigrew's "Handy Book" I find the harvest alluded to was there represented as reaped in 1864, or four years previously to mine, and the gross weight of 328 lbs. as not of

one but three separate straw hives—an old stock 92 lbs., its first swarm 160 lbs., and second swarm 76 lbs. Which version of this story are we to credit?—A RENFREWSHIRE BEE-KEEPER.

MANAGEMENT OF STEWARTON HIVES.

MR. PETTIGREW has completely misunderstood my notes which appeared in your Journal of the 3rd inst. In reply to "ZENO" he affirms that I recommend a mode of procedure which I most strongly condemned. I state that "All the slides are withdrawn between the stock boxes, so that the three form one hive with free communication between all the combs. As a rule only the outer slide on either side is withdrawn between the stock and the first super [Sometimes when honey is very abundant a second slide is either entirely or partially withdrawn], and this is a most essential point in the management, &c." Again, "You have thus a hive in two compartments, three stock boxes with free communication, &c., and three, four, or more supers, with equally free intercommunication, but cut off from the stock everywhere, except where the withdrawal of the outer slides has opened a communication."

Mr. Pettigrew is well versed in the management of bees in straw skeps, but appears to have had no experience in the management of Stewarton boxes, with the theory and practice of which he is manifestly altogether unacquainted.—J. E. BRISCOE, *Albrighton, Wolverhampton.*

BEE-KEEPING IN THE NORTH OF SCOTLAND.

SINCE the publication of Mr. Pettigrew's "Handy Book of Bees" great improvements have been made in the north of Scotland. Previous to its publication bees were greatly neglected and mismanaged. As soon as I read the work I put its lessons into practice, and shortly afterwards I gave my experience in two of our northern newspapers. In 1875 I wrote a small work entitled "The Scotch Bee-keeper," and, as might be expected, my teaching was almost the same as Mr. Pettigrew's. A few weeks after its publication I received many letters asking information regarding Mr. Pettigrew's book, which I at once furnished; this, of course, assisted the sale of the "Handy Book," and spread a knowledge of bee culture far and near.

Every week I receive letters from interested bee-keepers either asking questions or intimating their success. To-day (Oct. 12th) one has come to hand which I consider very worthy of publication. It is from Mr. Trorp of Birchwood Cottage, Corgarff, Strathdon, and is as follows—viz., "I have long intended writing you a few lines about my bees. I noticed with pleasure your communications in the *Banffshire Journal* many years ago, and I commenced bee-keeping about three years before you published the "Scotch Bee-keeper," of which I obtained a copy; and since that time I have united my bees at the end of the season instead of burning them in the brimstone pit. I have adopted your instructions regarding big hives. I have not any larger than 17 and 18 inches inside measure. I find that swarms from hives of the above size are about twice as large as the swarms I used to have from small hives. The season of 1877 was a trying one for bee-keepers. I had no swarms, but I lost none of my stocks. I had three stocks at the commencement of the season. I took my first swarm on the 8th of July, and by the 20th the same hive had given three swarms. My other two stocks both swarmed on the 17th July, and by the end of the month they had each swarmed three times. One of the top swarms weighed 5½ lbs., another 5 lbs. of bees. At the end of the season both of them weighed 82 lbs. gross. My other top swarm weighed 74 lbs. The parent of this top weighed 68 lbs. The other two swarms were 53 and 44 lbs. respectively, which is not bad for this late locality." The above results from such a late district as Corgarff are very satisfactory.

Before I conclude I may state that bees have done well this year over the whole of the north of Scotland. Several swarms have reached the weight of 130 lbs. My best top swarm built 13 square feet of comb and stored 80 lbs. of honey. A swarm of June 26th filled its hive and gave a super of 37½ lbs. of very fine honey. I may also state that my frame hives measure 18 inches from back to front and contain from ten to twelve frames. My straw hives measure 16 inches and 20 inches, and are about 12 inches deep. When working supers on the Stewarton system I place the empty one below the full one, and I have no difficulty in preventing brood in the supers. I cause the bees to build thick combs, hence they are all but useless for breeding purposes.—A. COCKBURN, *Aberdeenshire, N.B.*

OUR LETTER BOX.

TURKEYS' HEADS SWOLLEN (J. W. G.).—Your Turkeys are either suffering from the change of the weather, or if they are still with the hen she is allowed to drag them about in the morning while the grass is wet and damp. They are very susceptible to injury by cold. If they are with the hen keep her under her rip till the sun is up and the grass is dry. If they have left her shut them up till the chill of night, the white frost, and the icy dew are gone off, then let them out. From your description they are far gone in disease. Wash the heads of those affected with vinegar and cold water

mixed in equal parts. Feed them on ground oats, to which add a small quantity of bean or pea meal. Slake the whole with milk, and mix with it chopped onion greens. Give morning and evening a good feed of stale bread soaked in strong beer. Give every evening two pills of camphor, each the size of a large garden pea for adults, smaller for poults. If they do not improve give one pill in the morning. This treatment should cure them.

CAYENNE FOR CANARIES (W. M. G.).—Begin with a small quantity, and increase until a small teaspoonful is mixed with each egg. Use both white and yolk. It is effective with any variety of the Canary.

CORN COCKLE (F. G. H.).—We do not think the seeds are poisonous, but such inferior corn as you have sent us is bad poultry food.

BEES (R. Filmer).—"Bee-keeping for the Many," post free for five penny postage stamps from this office, will afford you useful information.

POTATOES AFTER LUCERNE (G. R. P.).—The best sorts of early potatoes are the Early Rose and Myatt's Prolific. These may be planted in February, and will be fit to dig up the first or second week in June, quite in time for drilling lucerne. In planting early potatoes, instead of putting dung in with the sets it is a good plan, especially if the horse or pig dung is composed of long fresh straw, to place it on the top directly over the sets. This preserves them against the night frosts, and in the act of hilling-up the dung is buried. If the land is out of chalk lime may be dug into the land, but not chalk with the potatoes, for it makes the tubers spotted and spoils their appearance for sale.

ABBOTT'S COMBINATION HIVES (F. J.).—"B. & W." has no personal acquaintance with Mr. Abbott's combination hive. He believes that most commonly bees build their combs from front to back, but it is by no means universal. For many years "B. & W." worked hives with bars across his hives; but now that he has adopted bar-and-frame hives *à la* Woodbury, his bar-frames all run from front to back.

PRICKLY COMFREY (T. James).—We can only suggest that you give frequent and liberal dressings of freshly-slaked lime and soot, so as to prevent your plants being devoured by slugs. The soot would further enrich the ground and increase the produce of plants. The lime is best applied at night when the slugs are active.

METEOROLOGICAL OBSERVATIONS.

REMARKS.

- 16th.—Foggy, dark, dull day.
17th.—Very foggy morning, cleared a little at noon, sunshine for a short time, but fog continued all day and evening. [calm starlight night.]
18th.—Rather dull but clear day; high wind, little sunshine in afternoon;
19th.—Fair day throughout, but dull; very little sunshine.
20th.—Fair in early morning, thick and dark from 9.30 A.M. until 2 P.M., especially dark at noon; dull evening.
21st.—Misty early part of morning, fine and bright after 10 A.M., very cloudy and dark from 2.20 till 3.15, fair but dull rest of the day; high wind from S.P.M.
22nd.—Low barometer in early morning, strong wind, heavy rain at 3.50 A.M.; clear sky and bright with sunshine after 10.30 A.M.
Dull and gloomy, temperature much the same as the previous week.—G. J. SYMONS.

COVENT GARDEN MARKET.—OCTOBER 23.

OUR market is badly supplied with Pears, importations from the Continent being short and prices high. Large quantities of Apples are again arriving from America, and meet with ready sale, but at unremunerative rates. Kent Cobs have sold freely.

From observations taken near London during forty-three years, the average day temperature of the week is 53.5°; and its night temperature 37.1°.

NOTES ON PEARS.

WITH the return of the planting season a few notes on the results of five years' experience of more than fifty varieties of Pears may be of use to your readers in making a selection of the best sorts to provide a continuous supply of first-rate fruit from August to March. It is comparatively an easy matter to name fifty or a hundred good Pears, but few gardens are large enough to grow so many, and the object of my experiments has been to test all the best-known kinds I could obtain as to their merits and time of ripening. I began by reading through the descriptions of Pears in Dr. Hogg's "Fruit Manual" and noting down all the best, the result being a list of four or five times as many as I could possibly find room for; but by arranging them according to the time of ripening as given in the "Fruit Manual," and carefully comparing their relative merits, I at last managed to reduce the list to between fifty and sixty, which were planted on the Quince stock and trained as oblique cordons on a wire trellis to obtain fruit in the shortest possible time. From the results of five seasons' experience I should make the following selection. *Dessert* :—

August.—Beurré Giffard, small; and Beurré de l'Assomption, large.

September to October.—Williams' Bon Chrétien, large; Souvenir du Congrès, very large; Madame Treyve, large; Beurré Superfin, large; Comte de Lamy, small; and Seckle, small.

October.—Louise Bonne of Jersey, medium size.

November to December.—General Todtleben, very large; Maréchal de Cour, very large; Thompson's, large; and Doyenné du Comice, large.

December to March.—Winter Nelis, small; Beurré d'Anjou, large; Nouvelle Fulvie, large; Joséphine de Malines, small; Bergamotte Esperen, small; Olivier de Serres, small; Prince Napoleon, small; and Easter Beurré, large.

For Cooking.—Catillac and Bellissime d'Hiver.

They are placed as nearly as possible in the order of ripening, and will provide a continuous succession. Beurré Giffard comes first and has proved superior to Jargonelle, which is generally considered the earliest good Pear. Citron des Carmes and Beurré d'Amanlis are not worth growing here. Beurré de l'Assomption ripens at the end of August, just before Williams' Bon Chrétien, is a very fine large fruit, perfumed, juicy, and of excellent flavour. Williams' Bon Chrétien is too well known to require description, and is followed by Souvenir du Congrès, which is very much like it, only larger and later. Madame Treyve is a large juicy Pear with a delicate noyau flavour, ripe in the beginning of September; and is followed by Beurré Superfin, another fine large Pear, with a delicate perfume and fine flavour. Comte de Lamy comes in about the same time—the end of September or beginning of October, and though small is a most delicious Pear, being very juicy and richly flavoured, comparing in this respect with Seckle, another small Pear of the highest excellence; Seckle being the richer of the

two, while Comte de Lamy is the most vinous. The birds, no mean judges in such matters, always select these two Pears; and this season, though discs of cardboard were placed over the fruit, as recently recommended by Mr. Radclyffe in the Journal, I have not secured a single unpecked fruit. Confound the little rascals, there is no circumventing them, and one feels sorely tempted to take one's revenge in lark pies, or to run over to Paris for a week to see the finish of the Exhibition and learn how they cook small birds. In this way one might even discover a use for the sparrow. But to return to our subject. The Pears hitherto mentioned, like nearly all early Pears, require careful watching when ripening, as they are liable to go at the core; experience is the best guide, but when in doubt play a trump—i.e., cut into one.

The next on the list, Louise Bonne, is *par excellence* the October Pear, and with proper management can be made to last a whole month, as it keeps for several days even when quite ripe, and remains sound at the core to the last. It is of medium size, very juicy, and of delicious flavour; but sometimes, especially with highly coloured fruit, slightly astringent. General Todtleben ripens in the beginning of November, is a very large handsome fruit with pink flesh, of a peculiar perfumed flavour something like rose water. It is well worth growing, but the fruit goes at the core, and the blossom is tender, being very liable to be cut off by spring frosts. About the same time Maréchal de Cour comes in, and is a fine large fruit with soft buttery flesh and abundant highly flavoured juice. Thompson's ripens in November, and is one of the very best—buttery, very juicy, and exceedingly rich. Another very good Pear is Doyenné du Comice, ripening from the middle of November to December; it is hardy, bears well, and produces fine large fruit, very juicy, rich, and highly flavoured; as good as a Peach.

The last five named are the pick of the autumn Pears, and if more are wanted Marie Louise may be grown, or British Queen, both very tender in bloom and liable to be cut off by spring frosts. Duchesse d'Angoulême, sometimes good, but generally gritty; Beurré Diel, large and showy, sometimes good, often mealy and insipid; Glou Morceau, uncertain, sometimes very good. These last three Pears are very fine as imported from the Channel Islands and France, but our climate does not suit them, except in favourable situations. Chaumontel is another of the same description; where it succeeds it has the great merit of ripening gradually, and consequently lasting over a long period. Goubault is a hardy free-bearing Pear, highly flavoured but deficient in juice. Gansel's Bergamot is good. Durondeau and Dr. Trousseau are very highly flavoured and juicy, but too astringent. Beurré Clairgeau is only a show Pear; and Doyenné Boussoch and Beurré Bachelier are very large and handsome, but utterly worthless. Forelle is very pretty and good for nothing. Beurré Hardy, Beurré Bosc, and many more might be mentioned, but with me they are not satisfactory.

Having disposed of the autumn Pears, we now come to the winter supply, which is always rather uncertain, as the time of ripening can no longer be relied on, varying more

or less each season. First comes Winter Nelis, a small Pear of the best quality, very juicy, and of the richest flavour; ripe about Christmas. On a wall it is improved in size but not in flavour. Beurré d'Anjou is a large buttery Pear, juicy and very good; ripe in December or January. Nouvelle Fulvie is one of the very best late Pears, being large, very juicy, and of delicious flavour; ripening in January for the three seasons that I have fruited it. Joséphine de Malines, generally ripe in February, is small, pink-fleshed, with rose-water flavour, very juicy, and surpassed by no late Pear when in perfection. Bergamotte Éspérén is another very good small Pear, and should be tried on a wall to increase the size; and the same applies to Olivier de Serres and Prince Napoleon, which I have only fruited for one season. Knight's Monarch has altogether failed with me, sometimes dropping its fruit, and in other seasons remaining quite hard till the end of February, and then shrivelling without ripening. For the autumn and early winter months we have more than enough Pears of the highest quality, the only difficulty being to decide which to select out of so many that are first-rate; but a good large late Pear that could be relied on to ripen well in February or March would prove a decided acquisition. Magnificent fruits of Easter Beurré are annually imported from France and the Channel Islands, but this Pear proves very uncertain in our climate. The first season I had it very fine, equal to the best foreign fruit; then for four years in succession it failed to ripen satisfactorily, sometimes remaining quite hard till midsummer. This season, judging by appearances, I believe it will prove good again, as the fruit is large and well developed, weighing from 8 to 12 ozs. each, and with a clear smooth skin free from blemishes. Beurré Rance is a large late Pear, exceedingly juicy, but deficient in flavour.

For cooking, Catillac and Bellissime d'Hiver are immeasurably superior to all others. As a curiosity Belle Angevine may be grown on a wall, but for use by all means plant all the Catillac you can find room for either as bushes or cordons.

To obtain Pears in perfection, especially the later varieties, a suitable storeroom is absolutely necessary. No Pear should be allowed to ripen on the tree, even the earliest varieties being gathered just before or while they are changing colour. A properly fitted-up fruit room is a great convenience, but any cool dry cellar will answer; the exclusion of light and maintenance of a uniform temperature being the chief requisites for keeping fruit, and a warm place to develop the flavour while ripening. I put mine in shallow boxes each holding about two dozen fruits, examining them occasionally to see that none decay, and when ripening the boxes are transferred to a warm cupboard behind a chimney with a temperature of 65° to 70°. The name of the contents with probable time of ripening is marked on each box.

An important point in the culture of the trees is to mulch well early in summer, especially for trees on the Quince stock, the surface roots of which are liable to suffer from drought, when, instead of swelling off to the full size, the fruit becomes stunted and cracks.—ESSEX.

ROSES AND ROSE SHOWS.

ROSE SHOWS were made for Roses, and not Roses for Rose shows. Most of those who write about Roses in "our Journal" seem to forget this. The election lists are made out as though the one object of everyone who grows Roses is to fat them up like prize pigs for the show boards. The biggest, and the fattest, and the roundest wins. He who can show twelve big, fat, and round blooms, the produce of five hundred bushes, does well; but he who can show forty-eight big, fat, and round ones from five thousand bushes does better—nay, he is a hero, a Hercules!

As "A PUPIL OF REYNOLDS HOLE" pertinently remarks, "for one exhibitor among those interested in Rose lore there are perhaps ten thousand who grow the Rose simply for the pleasure it affords to themselves and friends, loving it for the grace and beauty it sheds around their quiet gardens." And who shall deny that this quiet enjoyment, which excites none of the baser feelings of our nature, is quite a sufficient recompense for all the toil and trouble bestowed on the cultivation of this peerless flower?

Now, after this, would you be surprised to hear that I am an exhibitor myself? I am, indeed; but I candidly confess that exhibiting is only a secondary consideration with me. I do it, but do not altogether like it. The excitement and the

worry, and the hurry and the sounds of the conflict, have no charms for me. The Roses themselves never seem to me to look happy stuck up in stiff rows with an unnatural precision, and those who show them look even less happy, as with flushed faces and nervous fingers the work of "setting up" is carried on. How grand (not lovely; blooms are all grand at shows) the box looks now that the work is complete! But somehow I do not seem to enjoy the grandeur or feel grateful for the splendid ranks. The thought will occur to me, "Why do not the judges begin? That Jacqueminot, now so superb, will be gone in half an hour, and that fellow D cut his Roses twelve hours after I did. Mine will have no chance against his unless," &c., &c. This may be pleasure to "A LOVER OF ROSE SHOWS,"—who, by the way, can see no difference between La France and Capitaine Christy!—but to me, who am a humble lover of Roses, it is at the best painful fun and restless comfort.

Give me my quiet garden, where I can rest indeed and be thankful; where my Roses look up at me and I look down on my Roses with calm unruffled brow, and where my Jacqueminots come and go each in his own appointed time without fretful blowing to hasten, or swaddling bands to retard their brief career.

Thus it is that, although an exhibitor, I heartily endorse Mr. Radclyffe's opinion that the election should not be confined to Roses for exhibition only. If it is to be of use to the majority of readers we must put Roses first and Rose shows second. Indeed, seeing that the number of exhibitors and would-be exhibitors is so limited, is it not rather a mistake to speak and write so much about Roses for exhibition? Does it not deter some from using the lists and other information given from time to time who otherwise would do so? Would not a classification be more useful to the generality of readers which gave—

1st, The Roses which produce freely blooms of the finest quality suited for either garden decoration or show.

2nd, The freest bloomers irrespective of the quality of the individual blooms.

3rd, Roses which produce occasional blooms of first-rate excellence, but are too uncertain for garden decoration either from tenderness, bad habit of growth, or hard opening?

Space will not permit me to enter into details, but it will be interesting and instructive to see how this classification affects the present election lists.

First of all Class 2, a very interesting one, is altogether cut out, although it contains many valuable decorative Roses. Safrano, Rêve d'Or, and Goubault among Teas; Anna Alexieff, Comtesse de Chabillant among Hybrid Perpetuals; and Charles Lawson, Mrs. Bosanquet, &c., in other classes are examples.

Next it will be gratifying to the many who grow the Rose but never exhibit to find that at least thirty-six of the seventy-two named as best for exhibition are also equally, or nearly equally, good for garden decoration; that out of the twelve at the head of the list only two or three (Marie Baumann, Louis Van Houtte, and Etienne Levet) are in any way doubtful as garden Roses when grown moderately well. The first and second should be grown on the seedling Briar, and will then be found freer in growth than on the Manetti. Etienne Levet, though a splendid Rose, is of too stiff and unyielding habit ever to make a garden Rose.

In Class 3, for uncertain Roses, will be found those that it pays only the exhibitor to grow. Even he finds that he has to keep up a stock of about a hundred plants of each if he wishes to make sure of cutting one or two show blooms on any particular date.

It may be useful to intending purchasers to name a few of these splendid rogues. You must speak of a man as you find him, so that I am aware that I lay myself open to objections from those growers who in other localities find that they do better than with me.

First choose Marie Finger in preference to Eugénie Verdier. The latter is a bad grower as a cut-back, the former good in every way and a richer colour.

Avoid Etienne Levet, Comtesse d'Oxford, Capitaine Christy, Xavier Olibo, Horace Vernet, Duc de Wellington, Emilie Hausburg, Elie Morel, Lord Macaulay, Marie Cointet, Duc de Rohan, Niphets, and Reynolds Hole. All the above are bad growers as cut-backs.

The following open badly:—Monsieur Noman, Star of Waltham, Monsieur Boncenne, Duke of Connaught, Madame Lacharme, and Edouard Morren. Several others in the list are open to objections of various sorts; while, strange to say, Princess Mary of Cambridge, one of the best all-round light Roses

that exists, good for garden, show, pot, or forcing, is not so much as named in the election list.—R. W. BEACHEY.

WINTERING CALCEOLARIAS.

HAVE any of your correspondents wintered their Calceolarias in an orchard house? If not, allow me to recommend the following plan which has been successful here:—A one-light frame is placed in the house facing south containing about 3 inches of sandy soil, into which the cuttings are thickly dibbled, well watered, and closely shut for some time. The advantages are—air can nearly always be given, therefore damping-off is reduced to a minimum; the plants can be daily exposed to the light instead of being enclosed in darkness for a week as is frequently the case with the ordinary plan, and if extra covering be required, which will seldom be necessary, it will be dry instead of being saturated with wet. The frame is 2 feet 10 inches by 2 feet 11 inches, and contains about 320 plants. In April they are planted in a cold frame out of doors, and gradually hardened off for bedding-out in May.—C. T. H.

GRAPES NOT COLOURING.

"A KITCHEN GARDENER" in his remarks under the above heading, without actually committing himself to the opinion that the very intensely hot weather experienced during July was the cause of a slight deficiency in the colour of his Black Hamburg Grapes, is evidently very much inclined to think that such was the case. As he remarks, want of colour is a very serious affair indeed—in fact, is the one great drawback to many otherwise very fine crops. Intense heat may be the indirect cause of failure; at the same time two houses of Grapes in one locality under different treatment not unfrequently present a marked contrast, consequently all the blame cannot in fairness be attributed to the very hot weather.

Modern vineries being very lightly constructed, presenting a greater surface of glass, and therefore a proportionate increase in the heat conducted, undoubtedly require a light shading, and nothing is better than limewash put on lightly with a syringe. Unless this is done the intense heat causes a too rapid evaporation, which has the effect of deranging the healthy action of the function of the leaves. Where the root-action is good, and is stimulated with plenty of moisture and the usual mineral elements, the effect, extreme evaporation, is almost imperceptible; where, however, the opposite is the case the effect is soon perceptible both on the foliage and fruit. The check given to the growth is soon followed by an attack of red spider, which no amount of humidity will prevent, the two evils making an imperfectly coloured crop almost a certainty.

A defect in the colour of Grapes is often caused by the excessive use of fire heat without giving the necessary amount of moisture and fresh air so requisite to vegetation generally, and growing Vines in particular. Why insist upon the house being kept to a certain temperature without any regard being paid to the external atmosphere? Overheating pipes is in effect as injurious as excessive sun heat, and perhaps more so, as the latter causes a liberal supply of fresh air to be given, which is seldom the case with the former. A hot dry atmosphere undoubtedly contributes to an earlier formation of saccharine matter in Grapes, in my opinion, however, at the expense of colour. "A KITCHEN GARDENER'S" second crop will, I think, help to corroborate this theory, as no doubt he will find them, if not sour, far from being sweet. The Vines being ripening receive the full amount of air both night and day, and the house naturally is not so hot and dry as when the full crop was hanging.

My theory, therefore, is that Grapes should be allowed plenty of time to ripen, admitting air at all times in quantities more or less according to the external temperature. The front lights often are kept hermetically closed, instead of which during mild nights they should be open as well as the top. The latter during the earlier stages of the Vine's growth should as much as possible be kept slightly open during the night, as at this time the action of the plant although changed is still going on. An artificial and unwholesome air is very injurious to the Vines, hence the necessity of admitting fresh air freely yet judiciously. The foliage of Vines grown under this treatment is very robust, and much better able to withstand any evils that may threaten it, to the great advantage of the fruit.

The accompanying bunch was cut from a Vine carrying a

fair crop of fruit growing in a large span-roofed plant house. This house is very lightly constructed of iron, and is quite the reverse of being well adapted either for plant or fruit culture. No fire heat has been applied at any stage of the Vine's growth, and the house has been full of plants throughout. For the benefit of both the plants and Vines the house was usually closed early during May and June, but a little air was always left on at night. During the extremely hot weather experienced during July the house was usually left wide open both at top, bottom, and doors. The fruit was coloured early in August, but the Grapes are only now becoming sweet, simply because August was a very dull month, and no fire heat was applied, which would have been had the fruit been of primary importance.—W. IGGULDEN, *Orsett Hall*.

[The bunch is good; berries large, regular in size, and well coloured, but not quite of the first quality.—EDS.]

THE ROSE ELECTION.—No. 6.

IN forwarding to you the last of the election lists of the seventy-two varieties I would draw the attention of the readers of "our Journal" to the effect of removing the fourth-class votes in this election of seventy-two varieties. How materially it alters the position of several of the Roses! Of the twenty Roses that received fourteen votes half only would retain their position as obtaining the highest possible score; amongst these Duchesse de Vallombrosa is to be found. The remaining ten which would lose position include Maréchal Niel, Etienne Levet, Horace Vernet, and the Eugénie Verdier set; Dr. Andry, Duke of Edinburgh, and Madame Victor Verdier losing one vote each; the Ferdinand de Lesseps set and Sénateur Vaisse losing two, and Xavier Olibo three votes. Some of those that score thirteen votes are sadly cropped by this, notably Star of Waltham and Madame Lacharme, the former losing four and the latter no less than seven votes. Lower down in the list the changes by such action would be disastrous to the position of many Roses, which would be driven altogether out of the list, notably dear old Général Jacqueminot and Victor Verdier, whilst a few would rise materially—to wit, Marguerite de St. Amand, Camille Bernardin, and Capitaine Christy.

In the following returns of seventy-two varieties the Roses are placed as the first best twelve, second best twelve, next best twenty-four, and second best twenty-four exhibition varieties.

Mr. CRANSTON, *King's Acre, Hereford.*

71. Etienne Levat
72. Prince Arthur

I have only named one of the three (Ferdinand de Lesseps, Maurice Bernardin, and Exposition de Brie), as they are so much alike.

Mr. Bulmer in his list has rather enlarged on his idea of last year as to similar Roses; and although in his soil he sees less similarity in Alba Rosea and Madame Bravy than some do—and in this I confess that with my small experience of them I incline to his view—yet about several of them he has no hesitation in considering them so similar as to be either Cæsar or Pompey according to the fancy of the namer. Before another exhibition election we may know more about Marguerite Brassac and its similarity to Charles Lefebvre (to me the latter is many shades the darker), and La Rosière and Prince Camille de Rohan. It strikes me these may possibly be added to the list of similar Roses, which for purposes of election may be considered identical. I now give Mr. Bulmer's list, premising that in the bracketed Roses the vote is given to that which is named first.

I have arrived now at the completion of my task. In spite of errors and shortcomings I trust it may still be of some use to intending beginners of Rose-exhibiting; and although we cannot expect that all in the list of seventy-two varieties will be found universally useful, yet of this I am convinced, that very many amongst them are not robbers even to the garden Rose fancier; while to him who would succeed in the rosy contests of 1879 the large majority of those named in the lists are absolutely necessary, and will, brought to the highest state of perfection by skill, soil, and climate, charm the eye of the ignorant by their beauty, and arrest the fiat of the judges by their intrinsic exhibition qualities.

Once again in conclusion I tender very heartily my best thanks to all the voters for the help afforded me by their lists, begging them to receive these thanks collectively which time forbids me to send to each individually, and wishing to each of them some share of success in future contests with the Roses of their choice. After all those Roses are the best with each of us which prove to be *Al* on the day of exhibition, and which these may be is somewhat of a lottery; and hence most will require seventy-two varieties to stage forty-eight, a fact that large growers occasionally experience and smaller frequently learn to their cost. And thus to exhibitors and readers adieu.

—JOSEPH HINTON, *Warminster*.

THE VALUE OF PEAR WALLS.

DULL, cold, and wet was the spring, abundant the blossom on the fruit trees, giving rise to a passing gleam of hope—only a passing gleam, for hope of a crop of fruit vanishes before a succession of biting north-eastern gales, and it is only to trees upon walls of very genial aspect and in snug cosy corners that we could then turn for any signs of swelling fruit. Hard measure has Dame Nature dealt out to us during the last three or four springs, and well for us will it be if we can turn to account the stern lessons she has taught us. Weigh the matter well, regard it in all its bearings, and the result is inevitable of the supreme importance of shelter for insuring crops of Pears.

Of an extensive collection of Pears which I planted some six or seven years ago some were put inside a garden, others in an orchard, and others against walls of various aspects. Of all these trees, some hundreds in number, none have a good crop this season except those upon a wall facing the west, where the fruit of *Passe Colmar*, *Beurré Clairgeau*, *Fondante d'Automne*, and *Beurré Rance* is abundant and fine. The tree of *Beurré Clairgeau* on this wall invariably has a crop, and this year its fruit will be of especial service, not one of its representatives in the orchard having any. Of other sorts on this wall *Williams' Bon Chrétien*, *Maréchal de Cour*, *Doyenné du Comice*, and *Glou Morceau* have very little fruit, simply because they have made such robust growth annually since they were planted that blossom buds come more slowly upon them, but then when the trees do come into bearing the fruit will be much finer than it would had the roots been mutilated to induce a premature formation of blossom buds; and I am not only content to wait, but also anticipate an annual supply of fruit eventually from every tree in this favourable position—favourable not merely for shelter in spring, but for ripening the wood growth in autumn—a matter of vital importance. Without this wall I should have had very few Pears this year, and I commend it to the notice of all fellow sufferers who, although they may have no spare wall for fruit trees, yet probably have some sunny sides of outbuildings not yet turned to account.—EDWARD LUCKHURST.

CARPET BEDDING AT HAMPTON COURT.

A STRIKING example is afforded at Hampton Court of what may be termed the lasting beauty of carpet beds. Long after the regular flower beds were divested of their attractions, and even when the herbaceous borders assumed a "seedy" appearance, the carpet beds remained bright and ornamental. This fresh appearance of the beds, however, has been secured by artificial means. The beds are 24 feet by 12, and for each a canvas cover was provided, the cover being spread over the beds at night, and secured to pegs driven in the turf. Mr. Graham's object was to preserve the freshness of the beds

until November, and he has, except in the case of a few panels, such as *Alternantheras*, succeeded in that object. In future years the beauty of the beds will be still further prolonged, stocks of hardy low-growing plants suitable to this popular style of garden ornamentation being increased as rapidly as

possible. Even now a great portion of the plants employed are hardy or nearly so; indeed were it otherwise a sufficient number of plants for filling such large beds could not be raised with the extremely limited extent of glass at disposal.

In the bed, of which a diagram is submitted, hardy and tender plants are associated, the arrangement and finish of the bed constituting an admirable example of artistic leaf embellishment, for, as will be seen by reference to the mode of planting, no flowers are employed in the bed. The diagram is engraved because it is an excellent one, and because we have been requested to submit a plan adaptable to beds of the same shape as the one figured.

The carpet beds at Hampton Court and also in the London

parks are raised from 4 to 6 inches above the grass, this elevation adding considerably to their artistic appearance. Those intending to adopt this mode of decoration may well bear that point in mind at this the proper season of the year for making and preparing the beds.

BOTTLING FRESH FRUIT.

I WISH to say that I also had offered to me in the Paris Exhibition a similar recipe to the one spoken of in this Journal; but the fruit shown and said to be preserved in the same manner as the five-franc recipe was in glass bottles, was mostly divided into halves and quarters, and surrounded by what appeared to be a rich syrup. The plan of burning sulphur seems a very simple one, but do you think it would be likely to answer for any fruits besides firm ones, such as Apples and Pears? I am very anxious to find out some reliable way of preserving soft fruit, such as Damsons, Gooseberries, Currants, Cherries, &c., without the necessity of making them very sweet. This year I have succeeded with some bottles, whilst others have kept for a short time and then begun to ferment, causing the bladder to puff up. As all the bottles have been prepared in the same way I am very much puzzled to know why some bottles should keep so well. I have now a bottle of Gooseberries from last year's bottling perfectly good, and others fail through fermentation. My plan is—after filling wide-mouthed glass bottles with fruit they are placed over the fire in a fish kettle of cold water, which is gradually heated. When the fruit is cooked the bottles are lifted out and as quickly as possible tied down very carefully and tightly with bladder. Those that do keep are exceedingly good and taste like fresh-stewed fruit. If all the bottles would keep equally well I should be satisfied with my method. Can you or any of your readers suggest a cause why the result should be so variable? —A PUZZLED HOUSEWIFE.

NOTES ON ROSES.

I HAVE for some time past been intending to write on the *rexata questio* of Roses, Rose judging, and Rose elections, &c., but have not hitherto been able to find time or opportunity. I cannot resist saying something now, especially as the recent Rose returns given by Mr. Hinton are naturally calling general attention to the subject. First I must, with other rosarians, heartily thank Mr. Hinton for the trouble he has taken. I know from experience, though a lesser one than his, how difficult it is to get returns, and when you have them how much time and care are necessary to compile them properly. Mr. Hinton's return is very careful although elaborate, and great credit is due to him for his services to the Rose world, even *pace* "WYLD SAVAGE." I cannot help saying to my friend "WYLD SAVAGE," it would be better if he were to use a little more discretion with his zeal. To call an election such as last year's a mockery, snare, and delusion is a very good penny-a-line statement and may run glibly from the pen, but the old adage, "Think twice before you speak once" might be even better applied to writing. For instance, one who signed himself "A LOVER OF ROSE SHOWS," on the strength of what "WYLD SAVAGE" wrote about the two collections of Mr. Baker's and Mr. Jowitt's at Hereford, was induced to write to the *Journal of Horticulture* to find fault with the judgment, although he was not there himself and had seen none of the Roses. "WYLD SAVAGE" has so great a penchant for Teas himself, that a few more than ordinarily good Teas in a stand are sure to make him think the whole stand superior till he comes to take the points. With the difficulties he has to contend with in soil, and having also a forward climate, I am not at all surprised that he has found Teas repay his care more than other Roses; but (and this is a great but) no Roses are more liable to damage from damp weather, none that require more constant attention, none that do so badly in the neighbourhood of large towns or smoky manufactories. He seems to pride himself on having written down Gloire de Dijon, and yet it is classed as a Tea, and if I am not mistaken will regain the position of which it has been temporarily, and to my mind very unnecessarily, deprived. I say advisedly, Classed as a Tea, for I have always doubted and still doubt if it is a true Tea; and as in Mr. George Paul's Rose list, which I have just been looking through, he has suggested a new class of Hybrid Teas, so I am inclined to enlarge the list by putting in such Roses as Belle Lyonnaise, Climbing Devoniensis, Devoniensis, Gloire de Bordeaux, Ma-

dame Berard, Gloire de Dijon, Madame Levet, M. Trifle, &c., and I should also class Maréchal Niel in this list as being neither a true Noisette nor a true Tea. Cheshunt Hybrid, Cloth of Gold, and one or two others have been in my opinion hitherto placed in their wrong class; and while I mention Cheshunt Hybrid, though I was a good deal called over the coals for not sufficiently appreciating it, yet I cannot help remarking it has not won its way into either seventy-two, and though undoubtedly a vigorous grower and a free bloomer has not the quality ever to make it an exhibition Rose, nor will it ever rise above the character of a good garden Rose.

While speaking of "WYLD SAVAGE" and his zeal for Teas I cannot refrain from saying a few words to back up my friends Canon Hole and Mr. Pochin. They have both of them the disadvantage of backward climate to contend with, and in my friend Canon Hole's case (though in this he will not altogether agree with me) he has to contend also against a cold soil; and though a clay soil under good care may on the Briar and in favourable conditions produce the finest blooms, yet it is not fair to compare Roses grown by the ten thousand in warm climates at the early Rose shows and refuse the due meed of praise to the Roses produced under less favoured circumstances at later shows. But I go rather further still, and say, though I do not profess, as "WYLD SAVAGE," to attend every principal Rose show, that I have seen both Reynolds Hole and the Rev. E. N. Pochin show as good forty-eights, thirty-sixes, and twenty-fours as any I have seen exhibited by any amateurs. "Comparisons are odorous," as Mrs. Malaprop says, and there is no wisdom in setting up Hercules and his competitor on a pedestal. In saying this I have no wish to detract from the merit of either Messrs. Baker or Jowitt; and it was a great source of satisfaction to me, on meeting Mr. Baker as a coadjutor at the Crystal Palace this year, to find how entirely we were in accord as to our awards.

I do not glean that "WYLD SAVAGE" is altogether right about Catherine Mermet; it is 28 in one list and 23 in the other. But how about Belle Lyonnaise? It is 66 in one, I cannot find its name in the other, so that a second year does not make it superior to Gloire de Dijon in the general estimate; and I cannot help saying with regard to the last old friend, that if it came out as a new Tea, called we will say Monkton Wyld Hybrid, there would be as great an outcry as ever about it. Is there any Rose that blooms earlier, more constantly, or later?—any which will stand all the vicissitudes of climate, soil, or stock as it will? At present I know of none; and if I were asked what one Rose a man ought to plant I should say old Glory.

One thing: with due deference to "WYLD SAVAGE" and without wishing to depreciate nurserymen, I do not think they are by any means better judges of Roses than amateurs; and, as is often the case, mothers think their own children superior to anyone else's, so many raisers of Roses are inclined to put too high an estimate on their own seedlings. It is very difficult to look on one's own productions with an impartial eye. One thing certainly strikes me as strange in the recent election, that only one Rose—Marie Baumann—has secured universal suffrage in the first twelve; that only four Roses are mentioned in the first list of forty-eight varieties by everyone; and that any elector should altogether omit such Roses as Alfred Colomb, Etienne Levet, Maréchal Niel, Marie Rady, Marquise de Castellane, &c., out of the forty-eight and substitute some others in the place of them. I could name at least twenty that every rosarian should place in the forty-eight. In the second list of seventy-two twenty are named by all, and Alfred Colomb gains its more legitimate position, being two instead of seven. I cannot subscribe to the verdict that Marie Finger and Eugénie Verdier are identical, and I am equally sure that Exposition de Brie differs from Maurice Bernardin. I do not say the differences are great, but they are quite perceptible; and I fancy both Marie Finger, Ferdinand de Lesseps, and Exposition de Brie hold higher positions than they otherwise would have done had not all the votes been classed together. But this is only an opinion of my own, and is, like all private opinions, liable to correction.

I should like an election of new varieties, say, each year of three years from the current year—*i.e.*, in 1878 of Roses introduced into the trade in 1875, 1876, 1877, to name twenty-four, marking the first twelve, and to limit the electors to six amateurs and six nurserymen, the nurserymen to name the amateurs and *vice versa*. The election shows an inclination to enlarge on the merits of certain new Roses at the expense

of old friends, notably Duchesse de Vallombrosa and Capitaine Christy. I am pretty confident that the last is overrated, and its position in the second list, where it is 37 instead of 20, bears me out. I fancy Duchesse de Vallombrosa will prove a fine-weather Rose, and, like Mons. Noman, will by degrees fall out of favour. I have always, from the first time I saw and grew Marie Baumann, thought it the most perfect Rose in form, shape, and colour; in its own colour; and though I agree with Mr. Hinton I should like a little more vigour and strength in the neck, yet I believe the very fact of its being inclined to hang its head is one of the reasons why it produces so many perfect blooms. It is not scorched by the sun nor is it injured by the rain in the same way as some other Roses are. All Roses that have too soft an outer petal, and that catch the rain in the calyx and are injured by damp, may produce under propitious circumstances good blooms, but should not be classed among the premier Roses. Mons. Noman, Marie Van Houtte, M. Lacharme, are with me very liable to this, and as a general rule more than half the blooms either are glued together by the outer petals or rot off at the calyx.

I may conclude these remarks by saying that undoubtedly "WYLD SAVAGE" has the best of Mr. Douglas and "GILLY-FLOWER" about dressing Carnations, and I quite agree with "D.;" but as I have often seen Tea Roses tied to pieces of stick to support their heads, persons who live in glass houses must not throw stones. No dressing, tying, combing, &c., of any sort—no addition of any kind should be allowable; the only thing admissible is to remove a damaged petal.—C. P. PEACH.

HAMBLEDON DEUX ANS APPLE.

Two years ago I noticed in the fruit shops in a thriving town in Hampshire a large, roundish, greenish red Apple. These seemed to be abundant, and were for sale during the later winter months. There was a hardy, healthy, wholly unshrivelled look about them; indeed they looked as if they had only just been gathered, which at any rate could not be in February. Upon inquiry I found that the owners of the shops called them, as I understood the word, "Dusand." Upon asking how it was spelt the good women, possibly not being good in regard to their orthography, declined to say, adding, however, "that they were a good old-fashioned sort, and that there were plenty thereof." The Apples were so weighty and firm, and I was assured, which I fully believed, that they were capital keepers, that I felt interested in them. Being convinced of their excellence I searched on my return every catalogue in my possession; still no Dusand. I hunted the name in the "Fruit Manual." I ran my eye along the synonyms in that same work; still no Dusand. Not long after, if my memory serves me right, our old friend Mr. Robson mentioned in one of his articles the Apple Dusand with commendation. Here, then, was an additional proof and evidence of its goodness. Bearing this Apple in my mind I was still determined to find all about it and its right name; so on a recent visit to the same town I went to the nursery (a very good one, by the way, for a small town), and asked after a local Apple called Dusand, but received for reply that no such Apple was known in those parts. I replied that the thing was impossible, as they abounded in the fruit shops there. The foreman I addressed looked up and looked down. I might, if given to romancing add, "he took off his hat and peeped in the crown;" but I rather think without romancing he scratched his head, which seems often an aid to memory, possibly a sort of counter-irritant, like a mustard plaister to the chest. Well, the result of the foreman's appeal to memory was, "Surely, sir, you mean the Dewsum Apple. We have plenty of them, and capital croppers they are, and healthy trees too, and the Apples are such good keepers." Where do they come from? "Why, from up the country, where they are very common." I left the nursery, and found from a friend that the large village of Hambledon was in the direction indicated; and I concluded, and I believe rightly, that the correct name of the Apple is Hambledon Deux Ans, which paraphrased means that this Apple will keep two years, a strong proof of the good quality of long remaining in a cooking condition.

But my search was continued. Upon telling my story to a gentleman long a resident in another part of Hampshire I was told that he knew them by the name Jewsums, and, as the lady smilingly added, "called by our old man the Juicyuns." She also added that they are capital keepers, and need not, if room be lacking, be laid so apart as others, but will keep "like

Potatoes." Here, then, we have that good capital Apple Hambledon Deux Ans, which has travelled to Dusand, Dewsum, Jewsum, even to Juicyuns. Of the great merits of the Apple I have no manner of doubt—good cooking, not waste in cooking, and long keeping. And mark you, good keepers are some years bad keepers, as this year; and a hard, heavy, unbruisable Apple that really will keep to late on in the season is doubly valuable. My own opinion of Hambledon Deux Ans is so high that I have ordered some trees to add to my collection.

In conclusion I will quote the account from the "Fruit Manual," which is so accurate that I chiefly identified the Apple from that account.—"Fruit large, 3 inches wide, and 2½ inches high; roundish, rather broadest at the base. Skin greenish yellow in the shade, and dull red streaked with broad stripes of deeper and brighter red on the side next the sun. Eye small and closed, set in a rather shallow basin. Stalk short, inserted in a shallow cavity. Flesh greenish white, firm, crisp, not very juicy, but richly and briskly flavoured. One of the most valuable culinary Apples, and not unworthy of the dessert; it is in use from January to May, and is an excellent keeper. This variety originated at Hambledon, a village in Hampshire, where there are several trees of a great age now in existence."—WILTSHIRE RECTOR.

MARIE VAN HOUTTE ROSE.

THE Rev. W. F. Radclyffe and "A PUPIL OF REYNOLDS HOLE" have both sung the praises of various Roses, so, perhaps, I may be pardoned for once more extolling that splendid Tea Rose Marie Van Houtte. More particularly as an autumn Rose do I wish to recommend it. No Rose blooms so late and so freely with me as does this lovely Tea.

The other day I had a request from a lady to send her some white or yellow Roses for a funeral, "if I had any late ones still left." I was able to send her a fairly large basketful of Marie Van Houtte. The blooms, too, were equal to any, if not superior, I had in the summer. On November 4th I hope to bring you some myself, to show you how good a bloomer this Rose is in the late autumn. Herbaceous plants like Chrysanthemums which bloom at this season are indeed most valuable, but are nothing in comparison with Tea Roses.

Marie Van Houtte is with me the most vigorous grower of all Teas, and I cannot understand her low position on the poll. It must be that this Rose requires a mild climate so that many cannot grow it, for I am sure if the electors could grow such blooms as those I am alluding to this Rose would be in the first twenty-four. I am strengthened in my opinion by Mr. Cranston, who classes this Rose as a moderate grower in his catalogue. I have written to him on the subject, and he assures me that with him she is a moderate grower. At Exeter she grows as vigorously as Cheshunt Hybrid.

After Marie Van Houtte as a late bloomer I do not think there is a better one than the old Rose Jean Pernet. I cut a bloom of this Rose this morning equal to any Cloth of Gold I have ever seen. I do not believe that many people grow Jean Pernet; if I am correct I would advise all to procure some plants this season. Triomphe de Rennes and Céline Forestier are both good late bloomers, and Souvenir de Paul Neyron does much better in the autumn than in the summer. I do not find either Catherine Mermet or Souvenir d'Elise good this season, at least I have not this year cut any blooms.—WYLD SAVAGE.

NOTES AND GLEANINGS.

FOR his extraordinary and well-sustained energy as an exhibitor of plants, &c., at the PARIS EXHIBITION Mr. John Wills has been honoured with the grand prize in the horticultural section, also a gold medal. Gold medals have also been granted to Messrs. James Boyd & Sons, Paisley, for a conservatory; to Messrs. Sutton & Sons, Reading, also a silver medal, for seeds, &c.; to Messrs. J. J. Thomas & Co., 285, Edgware Road, London, for wirework for horticultural purposes; to Mr. E. Lumby, Halifax, also silver medal, for hot-water apparatus. The five gold medals awarded to Messrs. James Carter and Co. were noticed last week. Silver medals were granted to Messrs. E. Webb & Sons, Wordsley, Stourbridge, for preserved vegetables, and a bronze medal for seeds; to Messrs. Boulton & Paul, Norwich, for a conservatory; to Mr. J. Cavan Fox, South Kensington, for rustic buildings; to Messrs. Barnard, Bishop, & Barnard, for galvanised iron gates; to Messrs. Saynor, Cooke, & Rydal, for garden cutlery; to Messrs. Hartley and Sugden for heating apparatus; and to Mr. B. Edgington

and Mr. J. Unite, London, for tents. Several bronze medals were also awarded for products relating to horticulture.

— WE are requested to state that the portrait of the REV. M. J. BERKELEY, which has been painted by Mr. Peele for a few subscribers, will be presented to the Linnæan Society on Thursday next, November 7th, at 8 P.M. The presentation will be made on behalf of the subscribers by Sir Joseph Hooker. The portrait will be open for public inspection at all reasonable times. Those who have not yet sent in their contributions should do so without delay to the Hon. Treasurer, Dr. Hogg, 99, St. George's Road, Eccleston Square; or to the Hon. Secretary, Dr. Masters, 41, Wellington Street, Covent Garden.

— A CORRESPONDENT writes of an OAK standing in the churchyard fence of Headcorn in Kent. The girth of the trunk, he says, at about 5 feet from the ground is exactly 30½ feet.

— THE REV. W. F. Radclyffe states that he finds the SEEDLING BRIAR excellent as a stock, and as soon as Roses on it can be bought at the same prices as those on the Manetti he will buy them largely. He has the following Roses on the seedling Briar, which do excellently—namely, Marie Rady, Baronne de Rothschild, Maurice Bernardin, Pierre Notting, Reine Blanche, Marquise de Castellane, and Gloire de Dijon. A sign of brood has not been seen on them.

— PRIZES for GARDEN PRODUCE were competed for at Clonmel on the 23rd inst.—namely, a silver challenge cup given by D. H. Higgins, Esq., for vegetables, and a similar cup given by Lord Lisimore for fruits. His lordship's gardener, Mr. J. Wilshe, secured both the cups, having now won them two years in succession with collections of very great merit.

— THE best of all the white varieties of Mignonette that we have seen is GARRAWAY'S NEW WHITE. Its distinctness is not fully appreciated unless it is seen growing in large masses, when its whiteness is very apparent. We recently saw large beds of it in Mr. Cannell's grounds at Swanley, where this and other varieties are largely grown for affording cut flowers and seed. Miles's "Spiral" is the more luxuriant in growth, but Garraway's is preferred for bouquets.

— ONE of the most graceful of trees is the WEEPING WILLOW, and yet comparatively few trees are planted for purposes of ornament. Its scarcity in gardens is perhaps attributable to the idea, which is pardonably common, that the tree will only thrive satisfactorily in moist soils and positions. We have recently seen handsome examples of this Willow growing in dry gravelly soil in the suburbs of London, and while most of the surrounding trees were leafless or nearly so the Weeping Willows were green and attractive. It is one of the most suitable of trees for planting near the boundary fences of gardens abutting on public thoroughfares, its light green drooping foliage contrasting effectively with all other trees, while the tree overhangs just sufficiently to display its beauty without being obtrusively inconvenient.

— AMONGST the most distinct of TUBEROUS BEGONIAS are *Roseflora* and *Queen of Whites*. Messrs. Veitch have been fortunate in raising another variety of this type with bright crimson flowers, thus completing a trio of Begonias of great usefulness. The new variety possesses great substance of petal, and is remarkably rich in colour. The flowers of these Begonias are quite upright, and their stems proceed direct from the root. The plants flower with great freedom when planted out in cold frames.

— AS a small-growing tree for suburban gardens few excel the MOP-HEADED ACACIA, *A. inermis*. This distinct tree combines compactness with elegance in a remarkable manner. Some attractive specimens may be seen in Mr. Spurgeon's garden at Balham, the heads of the trees showing attractively above the evergreen shrubs amongst which they are planted. The renowned preacher appears to be an admirer of evergreens, for the front garden is not only densely filled with them, but small specimens in pots crowd the sills of all the windows, which impart to the pretty villa a snug home-like appearance.

— KIRKOVA (Turkey) is, says the *Daily News* correspondent, a little Garden of Eden—without the serpent. It is situated in a little nest of hills, clothed from base to summit with stunted Oak and Walnut trees. Every available spot of ground within a radius of a couple of miles is cultivated. Maize, Corn, Oats, Melons, and Vines flourish in profusion. From the door of the little hut in which I have found shelter

for the night I can count at least a dozen species of fruit and vegetables; Vines laden with yellow and purple Grapes are climbing Plum trees, the branches of which are borne to the ground by the weight of golden fruit; whilst luscious Water Melons, red, yellow, and pink, straggle here and there amongst the Indian Corn, shaded at irregular intervals by Pear and Apple trees. There is no post here, no telegraph; and if you speak to a native of this little village about a newspaper, he will probably think it is something to eat. But ask him for Melons, Grapes, Plums, Apples, Pears, or Blackberries, and he will overwhelm you with them at about half a farthing a pound.

— UNDER the heading of "A Roman Scourge" the correspondent of a daily paper describes the following mode of FORCING THE SALE OF VEGETABLES:—The *bagherini* are most fatal to commerce. They come at the very earliest hour to market, they sidle up in groups of four or five to a cartload of vegetables, and, as if for mere form's sake, they ask the price of it. After a long negotiation the *bagherino* flings a leaf upon the load, thus making it understood that he has acquired it; his confederates, like so many porters, immediately pounce upon the produce, and in a twinkling it is distributed among the retail dealers. In vain does the unfortunate owner resist this daily organised forcing system; his cries, his protests, his struggles, are alike unheeded; "the contract," he is told, "is concluded," and he cannot revoke it.

FROGS AND STRAWBERRIES.

IN the interesting article on page 289, on the culture of Strawberries, I find that frogs are charged with the crime of gathering and devouring the fruit. I believe that this is a case of involuntary false witness against the harmless Batrachian. The little heaps of Strawberries are gathered by mice for the purpose of extracting the seeds at their leisure. Having done so they have no further need of the fruit. But not so our slimy acquaintances the slugs, which rejoice in the repast heaped up for their delectation. Against them thus employed advances the frog, and rapidly transfers them to his maw. If, then, he is found sitting on the gathered heaps of Strawberries he is not to be ignorantly taken as the delinquent. He should rather be regarded as the gardener's friend, ridding him of his hated foes the slugs, which, though they have sins enough to answer for in all conscience, yet in this case are not the primary malefactors, but the nimble-footed mouse.—F. T., Dublin.

THE WARS OF THE ROSES.

I HAVE waited several weeks to see if anyone would answer Canon Hole's strictures on my remarks upon his place in the Rose contest. As none of those interested have done so I must conclude that they agree with Mr. Hole, Mr. Pochin, and others, and consider that I was not justified in relegating Canon Hole to the position of third best. This being so, and it being evident from the severe way in which he wrote about me that he considers himself very much hurt at my placing him in that position, I write to express my regret at having so placed him. And, indeed, I was not justified in so doing, as on consideration it is evident that a first prize at the Manchester National Show is equal to a first at the same Society's show at the Crystal Palace.

I hope that this explanation and apology will be satisfactory to Canon Hole and any other exhibitor in the midland counties who may consider that I have done injustice to so excellent a rosarian as the author of the "Book upon Roses."—WYLD SAVAGE.

SCHOMBURGKIA UNDULATA.

AS I directed my steps from Bogota in the direction of the Llanos, or the great Savannas, in the territory of St. Martin (New Granada), I came across this beautiful Orchid growing abundantly on the glittering schistose rocks of Quetame. Those bare rocks on which it grew, composed as they were of strata of a peculiar nature, inclined very often at an angle of 45° and even more; others, again, being quite in a vertical position, mostly presenting what is termed in geology a discordant stratification. Each strong pseudobulb had two broad and long leaves, leathery in texture and of the darkest green, from which rose the flower stem to the height of 3 feet to 4 feet 6 inches; on its extremity a beautiful cluster of flowers with undulated divisions, of a dark violet colour and with a red labellum, surmounted by large drooping bracts of a beautiful

rose colour, reminding one of certain *Billbergias*. The plant, however, has been known some time. M. Linden discovered it in 1841 on the Guayra, afterwards in Truxillo (Venezuela), and again in 1843 on the rocks close to the celebrated bridge of Icononzo at Tandi, New Granada. I have myself found the plant afterwards in 1876 on the rocks of Tandi, where M. Linden discovered it thirty-three years before. I also saw it again at

Panche and on the Rio Dagna, Columbia. The specimens which had served Dr. Lindley for the description and the naming the species ("Bot. Reg." xxx., 1844, p. 21) came from the Guayra. Afterwards Wagener on his tour in Ocana came across them again, as well as other travellers who sent living plants to Europe; yet for all that *Schomburgkia undulata* remains a comparatively rare plant.

Fig. 54.—GATHERING *SCHOMBURGKIA UNDULATA*.

The general complaint is that it does not bloom very freely. I firmly believe that the chief cause is improper cultivation, and that with suitable treatment it can be made to flower as freely as in its native habitat. All the plants I sent to M. Linden, which are now in perfect health, I got from the schistose rocks of Quetame, and very often endangered my life to reach them. The plants attach themselves with their strong roots tenaciously on the surface of the rock exposed to the full blaze of the sun. The altitude on measurement I found to be 6300 feet above the level of the sea, consequently quite a temperate region (*tierra templada*). Not a single drop of rain ever reaches them during the dry season. The only other

vegetation to be found are a few puny *Thibaudias*, some plants of *Marcgravias*, and an *Anthurium* resembling *acaule*, all tenaciously hooking themselves on to the dreary rocks. I found the plants in January, consequently in the middle of summer (*verano*). The flowers of this grand Orchid displayed their full beauty without suffering in the least from the effects of the long-continuing dry season. The foregoing will give an idea of what is required for the *Schomburgkias*. During their period of rest, which is generally between September and January, they must be kept perfectly dry, and even be allowed to flag, in a dry temperature of 65° to 78°. The blooming season being over, about March, they should then be subjected

for about five or six months to a humid atmosphere, so as to produce vigorous pseudobulbs and leaves. I am certain that if the above treatment is followed out plants of *Schomburgkia undulata* clothed with fine foliage and surmounted with magnificent flowers will be the result, proving a valuable addition to our Orchid houses.

I shall feel happy if by these remarks I have contributed to the better cultivation of those plants.—ED. ANDRÉ (in *Illustration Horticole*).

WOODWARDIA RADICANS.

I HAVE a *Woodwardia radicans* in my hardy fernery which is greatly admired. It has been planted out four years, and is protected during the winter months by a large bellglass, the fronds being wound closely round the crown. This year it has thrown up four fronds of the following dimensions—4 feet 1 inch by 2 feet 4 inches, 4 feet 2 inches by 1 foot 11 inches, 3 feet 9 inches by 1 foot 11 inches, and 4 feet 10 inches by 2 feet 3 inches, also two others not yet fully developed. The tops of last year's fronds, four in number, were pegged down some time since and have formed nice young plants.—C. T. H., *Osmington, Weymouth*.

[The growth recorded is very good.—EDS.]

GRAPES AT THE RED ROSE VINERIES.

The Grapes at this place—so graphically described by Mr. Wright some time since, are just now well worthy of seeing. When the extraordinary weight of the crop is taken into consideration, the great wonder is that the fruit ripened at all, but on the contrary, both fruit and wood are attaining perfect maturity.

At the time of our visit (October 14th) the sight of so many splendid Grapes in one house was simply magnificent, among the most noticeable being *Gros Colman*, which is colouring splendidly, and with a fine, deep, rich bloom that betokens an excellent finish. *Lady Downe's* also looks fairly well, but this variety would appear to have got out of favour there, seeing that Mr. Witherspoon has not planted a single cane of it in his new house. The best and finest looking Grape there is certainly *Black Alicante*; its noble appearance combined with excellent colour and great size of berry makes it the best of all market Grapes. Another good property that ought not to be lost sight of is its good keeping quality.

Among Grapes that have not done well there, and indeed they are the only ones, are *Dr. Hogg* and *Mrs. Pince*. The former has certainly kept its reputation for not shanking, but has displayed a constitutional weakness that has prevented it from maturing its fruit, and the berries have shrivelled up to one-half their original size. As to *Mrs. Pince* I should think that there has been an insufficiency of heat, as it, too, has not effected the desired maturation.

The great average excellence of the fruit is equalled by the superb condition in which we found the wood of the Vines, which is assuming that fine brown tint, hard firm appearance, and, what is of most importance, full plump eyes, so indicative of perfect maturation, and so full of promise for another year. This is to our thinking a matter of more import than the produce of a heavy crop, for let the next season be ever so favourable if the wood has not been perfectly ripened the previous year all our labour is lost, and the condition in which we found Mr. Witherspoon's Vines certify that he is fully alive to this important fact.

Just a word about the house referred to above. The young Vines in this house, planted this spring, have already reached the top of a 14-foot rafter, while a very great number of spring-struck eyes are noticeable for their vigorous growth. On inquiry Mr. Witherspoon informed us that these young canes were grown in pure turf, and watered with pure water, not a stimulant of any kind being used, and the healthy condition of both canes and roots which we examined bears out Mr. Witherspoon's assertion that nothing more is needed.—PETER FERGUSON, *Gardener, Weardale*.

BROWN & TAIT'S ECLIPSE CAULIFLOWER.

I HAVE been cutting heads of this variety for nearly a month from the same sowing, and I consider it the best Cauliflower for autumn use I ever grew. It is dwarf, compact, and the heads until too large for the table are well protected by the leaves; the quality is also good. I sowed in March on

a slight heat with a little protection, pricked out the plants as soon as large enough, and planted them out before they became stunted. They received one watering, but the ground was in good condition, it having been bastard-trenched in March after a crop of Coleworts, trenching-in stems, leaves, and all rubbish to hand. I intend growing this Cauliflower more extensively next season, as, having a large establishment to supply, it is essential that the best should be grown and in great quantities.—J. GADD, *Thorndon Hall*.

[The Cauliflower received was extremely fine, large, white, close, and of superior quality.—EDS.]

TURKEY COURT, MAIDSTONE,

THE RESIDENCE OF JOHN HOLLINGWORTH, ESQ.

MANY readers of the Journal have perhaps found out, like myself, that there is no paper preferable for writing on to the original Turkey mill (I say "original," because it has had many imitators, but they have fallen far short of the copy); but probably few know that the mills where it is manufactured are the property of one of our veteran Rose-growers, who has this year taken a new lease of power, and has astonished the natives by the beauty of his Teas. As long as I have known anything of Rose shows I have known "honest John Hollingworth." Many Rose-growers have met him, and will not perhaps be sorry to know something of the quaint old place which so exactly corresponds to its owner, or rather I should say its owners, for he and his brother alike take an interest in the place; and as I recently paid him a visit I will endeavour to give some idea of the place.

Turkey Court, the residence attached to the mills, is situated in a valley about a mile from Maidstone on the small river Len, which takes its rise at Lenham between Charing and Maidstone, and flows into the Medway a little further on. The Stour also takes its rise in the same parish, the one running east and the other west. I have been told the streams issue from the same field, but of this I cannot speak with certainty; the Stour at any rate has other sources, one of them being a remarkably strong spring in the parish of Westwell. Why these mills ever received the name they bear there is nothing to show. They have been in existence for many years, but in the writings connected with them there is no mention why the name was given to them. The place borders on the park of the Earl of Romney, the wall of the park being the boundary of the place on one side, and it is on this wall that the Teas are chiefly grown. But I anticipate. Let no one imagine that they are to see here a trimly kept rosery. The whole place is delightfully *negligé*. I do not mean neglected, far from it; but it is mixed up, Roses, and Conifers, and herbaceous plants, without any attempt at order. Some years ago a landslip occurred close by the mills, which threatened to destroy them altogether and created great doubt as to how they were to be dealt with. Engineers were brought down from London, and various plans devised. As in such cases doctors differ as well as in others it was finally determined to cart it away and fill up a pond, and this constitutes the larger portion of the present garden. Here are planted in different places Conifers which have encroached by degrees on the paths, which are all grass. Here is a fine specimen of *Thujaopsis dolabrata*, here another of *Cryptomeria japonica*, and here some well-grown Cedars of Lebanon. Then again we come on a mound over which the variegated *Vinca* is rambling at leisure, and another equally well covered with the Japanese variegated Honeysuckle. Amongst these we find beds of Roses, and notably in a lower part of the ground near the house, but the soil does not suit them. Like my own it is too light and rich, will grow most things to perfection but not Roses, except in a part of the garden where they would be quite out of sight. Many of the plants, too, are past their best, and I doubt not there will be a grand renewal this autumn, but Mr. Hollingworth has hit on a Californian mine of wealth for his Roses.

I have mentioned the wall of Lord Romney's park. From it there is a bank sloping down to the garden composed of rich unctuous loam; this, which was pasture, Mr. Hollingworth has turned up. On this bank the Roses are and will be more extensively planted; and I very much suspect that, good an exhibitor as he has been, he will yet, if his life be spared, surpass himself. His is another instance of the undying love of flowers when once it is encouraged. He was a keen sportsman, but he is now obliged to leave the partridges and pheasants to other hands; and although he has frequently said that he would give up exhibiting he has not found it in his heart to

do so, and is about as keen at it as ever. He has many amusing stories to tell of his exhibition days, now extending over a period of five and twenty years, some of them against himself; as for example, how shortly after the rule was introduced that addition of foliage would disqualify, he took up a splendid stand of twenty-four to the Crystal Palace beautifully encased in foliage of the best quality which he had carefully selected from his healthiest trees. As he looked down the stands in competition he came to the conclusion that he was an easy first. Imagine his consternation, when he came in to see his victory, to find his beautiful foliage rudely scattered on the box and "disqualified" written on his card. "Didn't I look down the other boxes to see if there were not others in the same predicament as myself! but alas! no. I was the only one who had not noticed the rule, and consequently the only one who had to bear the punishment." Nor does he grudge to see the victory snatched from his hand by another. How enthusiastic he was over the "dark horse" from Lincolnshire who came down to Maidstone this year and carried off the prize, Mr. A. G. Soames. "It was," he said, "a pleasure to see such an eighteen; and although several of our local men said it was too bad, I was heartily glad to see such Roses go in and win."

Adjoining his own property he rents land from Lord Romney, a large pond wherein Water Lilies, Reeds, and other aquatic grow in wild profusion, and where is one of the most beautiful examples of the lovely deciduous Cypress I have for a long while seen. As I looked over these grounds in various directions I could not but think, What a good opportunity for a grower of herbaceous plants, what fine bogs might be made, and how grandly almost everything would grow in one or another position in the garden!

Nor must I omit one other feature of the garden, a range of vineries 100 feet long, and filled with some of our best descriptions of Grapes. The Muscats were very fine, and I do not think that I ever tasted such Grapes as the Canon Hall Muscats grown there. Madresfield Court was also very good, and assuredly it was Grape-growing made easy. No nasty stokehole to descend into, no need of watching fires; there was simply a connecting link between the pipes of the house and the mills, and the stream flowed on night and day; the temperature once arranged never altered, and all risks were avoided. What more delightful for a gardener than such an arrangement as this? It is quite in accordance with the character of our good friend that he never sends a pound of Grapes to market, but distributes them amongst his friends, costing him, as he says, a little fortune in baskets.

Need I add, for he is a true rosarian, that nothing could be more hospitable than his reception, and I am sure all who love his favourites would meet with the same kindness that I did? May he long exhibit amongst us—one of the very "straightest" of all our exhibitors.—D., Deal.

DRESSING CARNATIONS.

AFTER all that has been written on this subject there yet remains a point or two that requires clearing up, especially as regards the legitimacy of one fancier growing the flowers and another fancier dressing them. Mr. Douglas has given direct evidence that dressing is all-powerful in winning prizes, for he has stated on page 242, in reference to some Hyacinths that he dressed for another exhibitor, that "they would have found no place in the prize list if they had been exhibited as grown," and further adds, "but I dressed them for him, and they obtained the first prize," and then asks "Who ought to have received it?" Most people, I think, who weigh the matter fairly will consider that the prize ought to have been shared between the grower and the dresser.

Subsequently it was suggested by "WYLD SAVAGE" that Mr. Douglas himself, who wins so many prizes, "does not dress all his own flowers." I quite thought that Mr. Douglas would have denied the imputation; indeed, I rather expected that he would have galloped in on the donkey he introduced on the page quoted and trampled the poor "SAVAGE" to death. Neither donkey nor rider have, however, since shown themselves in the arena. Instead of doing so your excellent correspondent "GILLYFLOWER," on page 311, answers for him, admits the truth of "WYLD SAVAGE'S" utterances, and makes an excuse for his friend Mr. Douglas. That excuse as put is a reasonable one; but the question is, Was it a matter of pressing anyone who happened to be present at the show to assist him in staging his flowers in time?

I have been a grower of Carnations in a small way for many years, growing about a hundred pairs. I have exhibited at local shows, and have been fairly successful in obtaining prizes; but I have not ventured to exhibit in London, neither am I likely to do so, for I feel that I should not be exhibiting under equal conditions if the practice prevails of allowing a grower to obtain the services of an expert dresser—dressing being, as Mr. Douglas has afforded evidence, of such primary importance.

For the purpose of judging of the quality of the blooms staged in London, and comparing them with my own, I made a long journey to see one of the National Carnation and Picotee Society's shows. I confess that many blooms surprised me, especially by the high quality of their dressing; but I was equally astonished to find an overwhelmingly greater number of inferior or inferiorly dressed flowers. While in the exhibition I entered freely into conversation with those surrounding the boxes. "Douglas first again," was the general buzz, and was responded to in various ways, one of which fairly startled me—it was, "Yes, and always likely to be when he gets Ben Simonite to go to Loxford to dress his blooms for him!" Thinking that a mere grumble of a disappointed exhibitor I took but little notice of it at the time, but now I think it fair to all who are interested that we should know whether the rumour which is evidently afloat is anything more than a rumour. Is it a fact?

I do not for a moment suppose that Mr. Douglas would do anything that he considered wrong or unfair; he has the reputation of being an honest exhibitor, as he is undoubtedly a good grower. It is evident that he does not think it unfair to dress another exhibitor's flowers and so win a prize for him, and it is therefore unlikely that he (Mr. D.) would object to another doing a like favour for him. But I, and I know others think with me, do not think the practice right. If I grow and dress my own flowers as well as I can I feel that I am seriously handicapped if I enter the lists against the best grower in England, who calls in the aid of perhaps the best dresser before he places his flowers in the stands. If that is not a "two-to-one" system of exhibiting I should like to know what is.

Your correspondent "GILLYFLOWER" writes admirably, also consistently, on dressing, and would "recommend that a prize be given for the best dressed flower, the dressing to be done at the exhibition, limiting the time of dressing to ten minutes," the object being, and an excellent one it is, to afford instruction to beginners in the art. Mr. Douglas must excuse me if I deem him less consistent. When "D., Deal," adduced his evidence against the excessive dressing of flowers Mr. Douglas was "down upon him" immediately, yet in a cutting from a paper that has been sent to me (not sent by anyone who has taken part in the present discussion) Mr. Douglas's name is attached to the following statement: "It is certainly better that the public should see and judge of the flowers in a natural state than when art has been employed to assist nature." That cannot be regarded as a youthful notion—an old opinion since departed from—for it was written in March of the present year. How does Mr. Douglas reconcile that statement with his acts of exhibiting flowers "dressed in the highest style of art?"—A STAFFORDSHIRE GROWER.

WORK FOR THE WEEK.

KITCHEN GARDEN.

THE haulm of Asparagus being ripe it should be cut off level with the surface, and after clearing off weeds, &c., dress the beds with salt, which will destroy slugs, &c., and at the same time act as a manure, applying it at the rate of half a peck per rod. If seaweed can be had it forms the best of dressings for Asparagus beds, and may be applied to the depth of an inch and covered with a little soil from the alleys, or a dressing 1 to 2 inches thick of rich manure may be employed, leaving it on all winter, forking it in carefully in the spring. Asparagus intended to be taken up for forcing should be covered with litter, so as to admit of its being lifted irrespective of frost. The leaves and stalks, if any are yet remaining, should be removed from Rhubarb and Seakale. For forcing those crops select roots which have not been cut or plucked, as those which have made an early and unchecked growth will have stronger crowns, and, ripening earlier, will start more freely into growth than those having received a check from cutting off the heads or plucking the stalks. Similar remarks apply to Asparagus. Seakale not intended to be lifted for forcing may be covered with about half an inch of ashes, and if a sprinkling of salt—about half the quantity given to Asparagus prior to putting on the ashes—is given it will do much in the way of slug destruction. Seakale intended for forcing under cover may be taken up

at once and be laid-in in a sheltered spot and be covered with litter, so that the roots may be readily removed as required. Rhubarb should have the surface soil removed from about the crowns with a fork, and a dressing of rich manure applied and covered with a little soil, the spaces between the rows and plants being well manured and forked in. That intended for forcing off the ground should be covered with litter, or it may be lifted and stored in sand or other material in a sheltered spot, and covered with some protecting material in readiness for draughting to heat as required. A few roots of Rhubarb and Seakale may be placed in the Mushroom or other house having a temperature of 55° to 60°, the roots being placed in moist rich soil, and no water given until growth takes place, then applying liquid manure. A bed may be made up of prepared dung and leaves duly fermented, and when the heat has risen and is found not to be too violent it may be planted with Asparagus, and managed as recently detailed by "A KITCHEN GARDENER." On a dry day take up Cauliflowers fit for use and store them in a pit where they can be protected from frost. Autumn Broccoli must also be attended to, or the heads now ready for use may be damaged by frost. Lettuces and Endives fit for use should be transferred to frames or pits without delay, having in readiness the requisite protecting material. Endive tied up may be sufficiently protected by an inverted flower pot, but the principal winter supply must be lifted forthwith. Cauliflowers, Lettuces, Radishes, or Parsley in frames or under hand-lights should have thorough exposure, employing the lights only in case of frost and during heavy rains, in the latter case tilting the lights. French Beans or Peas in frames should be matted up on cold nights and when frost prevails. Keep all autumn-sown or planted crops free of weeds, and in gathering Winter Spinach pick only the largest leaves, not cropping the plants too closely. If Chicory be wanted as an ingredient of salads roots may be placed in the Mushroom house. Pot a few roots of Tarragon and place them in a light airy position where forcing is or will shortly be commenced.

HARDY FRUIT GARDEN.

Autumn or early winter planting is preferable for all descriptions of deciduous trees, also Gooseberries, Currants, &c., therefore push forward the preparation of the ground for their reception. Good varieties of Pears for orchard planting are Lammas or Crawford, Caillot Rosat, Jargonelle, Windsor, Williams' Bon Chrétien, Hesse, Autumn Bergamot, Beurré de Capiaumont, Louise Bonne of Jersey, Aston Town, Marie Louise, and Swan's Egg. Stewing Pears.—Giglot, Black Worcester, and Catillac. Standard trees in orchards should be planted 24 feet apart.

Gooseberries, for affording quantity for tarts and market purposes.—Reds: Crown Bob, Farmer's Glory, Keens' Seedling, and Red Warrington. Yellow.—Broom Girl, Leader, Leveller, and Moreton Hero. White.—Antagonist, Queen of Trumps, Snowdrop, and Whitesmith. Green.—Green Overall, Hebburn Prolific. Random Green, and Heart of Oak. For bottling.—Rumbullion. For preserving.—Ironmonger, Red Champagne, Keens' Seedling, and Red Warrington. For dessert.—Red Champagne, Keens' Seedling, and Red Warrington. White.—Early White, White Champagne, and Crystal. Yellow.—Early Sulphur, Yellow Champagne, and Yellow Warrington. Green.—Green Walnut, Green Gascoigne, and Pitmaston Green Gage. Most of those are small and good, but the following dozen are large and of excellent flavour:—Red.—Companion, Speedwell, and Talfourd. Yellow.—Broom Girl, Leader, and Leveller. Green.—Heart of Oak, General Markham, Keepsake, and Thumper. White.—Lady Leicester, Snowdrop, and Mayor of Oldham. In rich soil Gooseberries should be planted in rows 6 feet apart and 5 feet in the rows; in soils not rich or heavily manured 5 feet, and 4 feet in the rows. Black and Red Currants should be planted 6 feet apart every way, a foot less for White Currants. Black Currants.—Black Naples and Lee's Prolific; Red.—Cherry, Red Dutch, and Ruby Castle; White Dutch.

Raspberries.—Plant in rows 6 feet apart and 5 feet in the rows in rich soil, and a foot less every way if the soil be only moderately fertile, Eastoft, Carter's Prolific, Prince of Wales, Red Antwerp, and Sweet Yellow Antwerp. Autumn kinds.—Yellow and Red October.

Strauberrries in Pots.—The earliest potted plants will now have completed their growth, and the earliest varieties will have the crowns fully developed and ripened. The pots should be plunged to the rim in ashes or cocoa refuse in cold frames, employing the lights only to ward off heavy rains, exposing the plants fully whenever the weather is favourable. Drying-off does the plants no good, but, on the contrary, causes the roots to become brown in appearance, whereas those plants kept moist have the roots white and fresh; therefore look over the plants carefully, and apply water whenever required. Those not required for early forcing should be plunged outdoors in a sheltered situation, and this before the pots become frozen, which is equally destructive of the roots as dryness.

FLOWER GARDEN.

The herbaceous or mixed border is a very suitable place in which to grow bulbous plants, as they are not disturbed there, and can ripen off the growth without being objectionable. Mixed borders, as they are mostly backed by shrubs, have shelter, which renders them very suitable for the different varieties of Lilliums,

the planting of which is very often deferred until spring; autumn is, however, very much the best time for planting them. Hyacinths, Narcissuses, Anemones, and the bulbous Irises are very beautiful, and should be planted extensively. From 2 to 3 inches deep will be sufficient for Anemones, but the Lillies should be planted 4 to 6 inches deep, and other bulbs in proportion to their size, placing a handful of sharp sand over the bulbs before covering them with soil. Alströmarias should be planted 6 inches deep. Ranunculuses of the Turban varieties and Pansies should be planted now, but choice varieties may be preserved in cold frames; prick off seedling Pansies in a sheltered border, or in pans or boxes. Pinks and Carnations must be planted out where they are to bloom, choice sorts being potted and wintered in a cold frame. In making up the beds for Pinks, Carnations, Picotees, and Pansies it is desirable to dig in a good dressing of soot and lime with a view of driving away wireworm. Gladioluses that have ripened their growth should be taken up and be gradually dried, as drying them too quickly and wintering them in a dry and warm atmosphere causes the corms to shrivel. Any strong-growing herbaceous plants that have outgrown the spaces allotted to them should, when the growth is ripened, be reduced to proper dimensions. Good cultivation is as essential for herbaceous plants as the pots of the garden. Any that have stood long in the same situation will be greatly benefited by an entire removal and replanting. This should be attended to early in the season, so that the plants may have time to become re-established before winter. The border should be trenched, working-in plenty of short manure and leaf soil before replanting.

PLANT HOUSES.

Stove.—Although shade is necessary in summer to prevent scorching there is no question of the importance of admitting all the light practicable when the sun is absent. More especially is this the case during the winter half of the year; for though there is very little growth made in winter as compared with summer, yet some plants will be more or less on the move during winter, hence the necessity of cleaning the glass inside and outside at this time of year so as to admit all the light practicable. This washing of the glass should be done more frequently than once a year, especially in smoky localities; indeed it should be done whenever the glass becomes clouded with dirt if the plants beneath are expected to be healthful. Summer-flowering plants will be going or gone, and the winter plants coming in, which being mostly of moderate growth associate well with still smaller-growing fine-coloured plants, such as Fittonias, Peperomias, Bertolonias, Tillandsias, the smaller-leaved Marantas, &c. Fittonias succeed admirably in either peat or loam, employed rather lumpy so as to admit of the water passing away freely. Cuttings root in a few days under a bellglass. *F. argyrea* and *F. Verschaffelti* are suitable for growing in small pots. If the crowns are divided of Peperomias and potted in sandy peat they will root and become established in a few weeks. *P. argentea* and *P. argyrea* are most desirable. Bertolonias grow well in peat and sand with a little leaf soil, cuttings striking freely in sand under a bellglass. *B. Van Houttei*, *B. splendens*, and *B. superbissima* are very beautiful. Marantas with several crowns may be divided, potted in small pots, and kept close, when they will soon become established. *M. albo-lineata*, *illustris*, *Lindeni*, *regalis*, *roseo-lineata*, *fasciata*, and *Mackoyana* are of moderate growth and suitable. Tillandsias *zebrina*, *tessellata*, and *musica* thrive in sandy peat in 6-inch pots. The preceding with many others—such as *Crotons* *Johannis* and *Weismanni*, *Curculigo recurvata variegata*, *Aralia elegantissima*, *Veitchii* and var. *gracillima*, *Pandanus Veitchii*, *Nidularia Innocenti* and *pictum* in small pots—make a grand display with the flowering plants that come in at the dull season. Gesneras of the *zebrina* section will soon be coming in. They must have plenty of water, but not too much, or the roots will perish, and if in small pots give them liquid manure occasionally, affording them also plenty of light. Perhaps no plants are so beautiful in late summer as Scarborough, Belladonna, and Guernsey Lillies in the greenhouse; and *Eucharis*, *Urceolinas*, and *Griffinias* in the stove, the latter being seldom seen, but their delicate white and blue striped flowers produced in succession for at least six weeks render them very desirable. Being evergreen they require to be kept moist at all seasons, watering copiously during growth; indeed the treatment given to *Eucharis* will suit them admirably. Keep a sharp look-out for mealy bug, scale, and at once destroy them; also thrips and aphids, subduing these by fumigation and sponging with soapy solutions. The temperature should be maintained at 65° to 60° at night, 5° less on frosty nights, 65° to 70° day by artificial means, admitting a little air at 75°, running up to 80° or 85°, closing at 75°. Syringing need only be practised in the morning and early in the afternoon; lightly if the weather be bright, but if dull damping the pathways will mostly be sufficient. Water only to prevent flagging, unless for any plants in growth, which supply according to their requirements.

TRADE CATALOGUES RECEIVED.

James Smith, Darley Dale, Matlock.—Wholesale List of Trees, Shrubs, and Conifers.

William Montgomery, Glen Nurseries, Cardross.—*Catalogue of Roses, Dahlias, Hollyhocks, &c.*

P. Sebire, Ussy, near Falaise (Calvados), France.—*Catalogue of Trees and Shrubs.*

J. B. A. Deleuil, Marseilles.—*List of Plants and Seeds.*

Frères Simon-Louis, à Plantières, Metz (Lorraine).—*Catalogue of Fruit and Ornamental Trees, Roses, &c.*

Souper et Notting, Luxembourg.—*General Catalogue of Roses.*

TO CORRESPONDENTS.

correspondences should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

ERRATA.—*Herefordshire Incumbent* writes in reference to his notes on Tea and Noisette Roses on page 308, that instead of the words "I have included in my list Souvenir de Paul Neyron," it should have run, "I have excluded from my list Souvenir de Madame Paul Neyron, as I consider Comtesse Riza du Parc a far superior Rose where they differ at all in depth of colour and substance." The date for the exhibition of the National Rose Society to be held at Manchester should be Saturday, July 12th, not 14th.

BOOKS (*Paddy Carey*).—If you require cultural instructions you will find them in the "Garden Manual," published at this office, post free 1s. 9d. The best moderately priced book on British and exotic Ferns is "Select Ferns and Lycopods," by B. S. Williams. It can be had from this office, post free, for 5s. 5d.

ROSE (*H. T. H.*).—The dark-coloured varieties being so numerous we cannot be certain of the name of your Rose, but we think it is Marie Baumann, one of the very best dark Roses in cultivation.

MOSS ON TOMBSTONE (*G. S.*).—Dust it well with hot lime, and in a fortnight or three weeks wash it clean with hot water and soft soap, using a brush for the letters.—J. G.

DAISIES ON LAWN (*W. L. C.*).—The Daisies were introduced with the turf, and they cannot be removed without expense being incurred. The only real remedy is to employ boys or women to dig them out with small forks. We have known large lawns cleared and kept clear by that practice. Where Daisies abound it is preferable to clean the ground and sow grass seeds than to form a lawn by laying turf.

DUMELOW'S SEEDLING APPLE (*James Bealey*).—The Apple mentioned in the catalogue you quote is the same as that referred to by "C. M." It is one of the most useful of late-keeping kitchen Apples. It is known in the south by the name of Wellington, and in the north as Normanton Wonder.

MILDEW ON FERNS (*M. E. R.*).—Mildew is generally caused by a close moist atmosphere, and especially when the roots of the plants are at the same time too dry. Your plants were probably affected with the parasite before they were placed in the hall. The remedy is dusting the fronds with flowers of sulphur, letting it remain on for a few days, then washing it off with a syringe.

GLOXINIAS IN GREENHOUSE (*Y.*).—The corns should be started in a heated frame about April, such as is employed for growing Cucumbers. By the time the Gloxinias have made some growth your greenhouse will be sufficiently warm, placing the plants in the warmest position, for the growth being continued and flowers produced. If you have no frame you had better defer starting the corns into growth until early in May; if started earlier the house will be too cold for them. Starting consists in watering the soil in which the corns are potted with tepid water. So long as the soil is kept dry the corns will remain dormant.

ROSES ON SOUTH BORDER (*Idem*).—The leaves falling from the trees which form the boundary of the border would not injure the Roses and other flowers nearly so much as would the roots of the trees by impoverishing the soil of the border. Such a border will require much water in summer, and also mulching with manure, to induce the plants to thrive.

TRANSPLANTING GOOSEBERRY BUSHES (*Notice*).—Enrich the soil in which you intend planting with plenty of manure. Lift the bushes carefully forthwith, retaining if possible slight balls of earth about the roots, retaining as many roots as possible, and in replanting take especial care to press the soil firmly but gently about them. The bushes should be 5 feet apart.

BED FOR BOG PLANTS (*Somerset*).—Slightly puddle the sides and bottom of the bed before putting in the bog earth, and let there be a constant flow of water through it all the year round. If you can clothe your bog earth with living tufts of sphagnum do so, and then plant among it your plants. Some of the best are Asphodels, Drosera rotundifolia, Crinum capense, the water Amaryllis, Gunnera scabra, Saxifraga aquatica, Grass of Parnassus, Loosestrife, Mimulus, Myosotides, Moneywort, and Menyanthes trifoliata. It will require no shade. A gravel path near or around it is advisable to enable you to visit it in damp weather.

UTILISING A VINERY IN WINTER (*E. G. J.*).—When you turn your Vines outside cover them with fern or straw to keep off frost, and take especial care to reinstate them in the house before the buds commence swelling in spring. Kidney Beans would answer very well in such a house during the winter months, and so would Cucumbers if you can afford them a bottom heat of 75°, and a top heat of 70° at night, rising 5° to 10° in the day. Do not try Mushrooms in so high a temperature, but you could force some Strawberries in pots, and also have some Rhubarb, Asparagus, and Sea-kale, which latter can be bleached very well by inverting flower pots over it and stopping the holes to exclude light. Bulbs, Lily of the Valley, Roses, and flowering shrubs might also be introduced if there is any available space.

PROPAGATING ARBUTUS (*G. C.*).—You can propagate the shrub by layering, which should be done forthwith, giving the shoots a twist and pegging them firmly in the soil.

CALCEOLARIAS DAMPING (*T. M.*).—We think with careful watering and judicious ventilation that both Calceolarias and Cinerarias will do well in your span-roofed house without any fire heat, at any rate at present, and much better than they would do in an airy verandah. Dry air, and especi-

ally when fire heat is employed, is very pernicious to those plants. We have frequently wintered the former successfully in cold frames, covering the glass with mats and straw, and lining the sides of the frames to exclude frost. Provided the temperature of your house does not fall below 35° your plants will be safe. We do not know the price of the stove you name, it varies according to size. Write to the maker, whose address you will have seen in our advertising columns.

INSECT ON GLOXINIA CORNS (*J. C. Ambleside*).—The larvæ forwarded are those of that troublesome weevil, *Otiorynchus sulcatus*. From their size it appears they have grown more rapidly in the autumn than is usual, but they would continue to feed during the winter, becoming pupæ in the spring. It is one of the species difficult to deal with, except by keeping a sharp look-out for the parent beetles in summer, when they will be found frequenting various succulent plants. A solution of ammonia has been applied by some of such strength as not to injure the plants, but usually the mischief is not discovered until the plants are beyond preservation.—J. R. S. C.

SCARLET GERANIUMS FOR WALL (*C. J. B.*).—For a low wall *Vestrius* is one of the most floriferous, and when planted-out in good soil grows freely. For covering a high wall *Warrior* is good. Both are bright in colour and keep as well when cut as any other varieties.

TREES FOR ORCHARD HOUSE (*H. W.*).—With a pathway up the centre 2 feet 6 inches wide, you will have beds or borders on both sides of it a little over 6 feet wide. Apricots succeed best in the pyramid or bush form. Peaches and Nectarines succeed either in the bush, pyramid, or standard form. Bushes and pyramids for such a house as that shown in your sketch would be most suitable, as you will not have height for standard trees. Of Apricots: Oullins Early, New Large Early, Peach, and Moor Park. Peaches: Hale's Early, Early Grosse Mignonne, Grosse Mignonne. Royal George, Violette Hâtive, Noblesse, and Barrington. Nectarines: Lord Napier, Stanwick Elrige, Rivers's Orange, and Balcowan. You may have a Vine trained over the pathway—Black Hamburgh or Foster's Seedling.

BLIGHT ON APPLE TREES (*Subscriber*).—From your description we think the trees are infested with American blight, which may be destroyed by dressing the parts affected with paraffin, diluted with about four times the quantity of water, keeping it well stirred; apply it with a brush, keeping it from the roots. If any insects appear next year during growth repeat the application, not wetting the foliage more than can be helped.

SHRUBS AND CLIMBERS FOR SOUTHWARK (*Flora*).—Of shrubs take Rhododendrons, Japanese Privet, Holly, Lilacs, Box, Escallonia macrantha, Double Gorse, and Portuguese Laurel. Of climbers take such *Honeysuckles* as *flexuosa* and *brachypoda*; try also the lovely *Ampelopsis Veitchii*, and we think *Berberidopsis* would answer; also *Cratægus Pyracantha*, which white and yellow-flowered *Jasmines*. *Escallonia macrantha* forms an equally good trailer and climber, and you could have no better substitute for Ivy in your Devon garden. The plants to which you refer are probably *Helianthus*, of which there are many perennial species.

CROWN IMPERIALS (*Old Subscriber*).—Leave the Crown Imperials undisturbed, enrich the soil about them, and in due course as they gain strength they will flower.

GLOBE ARTICHOKE (*Idem*).—The produce of Globe Artichokes is pretty much in proportion to the number of crowns to each stool and their strength. Plant in spring in tolerably rich deep soil, dig-in about them an annual dressing of manure, and you will find the number of "Globes" increasing yearly. We do not know where the "Sussex Anchor Hook" can be obtained.

TRANSPLANTING ONIONS (*G. N. R.*).—It depends entirely on the season as to whether your Tripoli Onions would be benefited by being transplanted before February. Probably they would not; but as the Onions are better able to withstand the winter by being thinned we should, if they are too thick, remove a portion of them at once and transplant them, leaving those in the seed bed about 2 inches apart.

CHRYSANTHEMUMS (*B. C.*).—The best time for propagating Chrysanthemums, both for making specimen plants and for producing large exhibition flowers, is in November, almost directly after the plants have ceased blooming. Select healthy and robust cuttings or suckers with a portion of root attached, pot them singly in 60-sized pots, and soon afterwards take out the extreme point, and encourage side shoots for the making of specimens. They should not be subjected to any coddling process, but should be placed in a cold frame, and have air always, except in unpropitious weather. Repot them as required, and stop the laterals when about 6 inches long until the second week of June. The number of shoots required to be left on a plant must be regulated according to the strength of the plant and the variety. We have seen well-grown plants of some varieties carry from eighty to a hundred fair blooms. Plants grown for producing exhibition blooms only are never stopped, but are allowed to grow up with one stem; later on in the season they branch out, and are generally allowed from three to six shoots, with a bloom on each, and when massed together produce a very striking effect.

ROMAN HYACINTHS (*Idem*).—To obtain a succession of these pretty miniature flowers all that are required for late use must be kept in a cold frame until wanted, the others being placed in warmth to bring them into bloom earlier. A temperature of 55° at night is sufficient. Roman Hyacinths are very valuable on account of their natural habit of flowering early.

CABBAGE PLANTS CLUBBING (*S. S. Whetstone*).—The "club" on your plants contains a small white maggot, the larva of a little insect called the weevil. If on the gall and its tenant being removed the plant is again placed in the field, where it is to remain unless it is again attacked, the wound usually heals, and the growth is little retarded. On the other hand, if the gall is left undisturbed the maggot continues to feed upon the albumen or young woody part of the stem until the period arrives for its passing into the other insect form, previously to which it gnaws its way out through the exterior bark. The disease is then almost beyond the power of remedies; it may, however, be in a great measure avoided by frequent transplantings, for this enables the workman to remove the excrescences upon their first appearance and renders the plants altogether more robust and ligneous, the plant in its tender sappy stage of growth being most open to the insect's attacks. Preventives recommended are heavy dressings of soot to the land, or applications of gas lime of from 8 to 10 bushels per acre, turned in with the spade or the last ploughing.

CLIMBER FOR TRELLIS (*R. A. M. J.*).—*Ampelopsis Veitchii* would do well in a box, and would cover a trellis facing north well during the summer; but for forming an evergreen screen nothing surpasses Ivy in such a

position. As flowering plants we have Clematis Jackmanii and Lonicera hexosa, growing and flowering well on a wall having a north aspect.

CELERY FLY (*Rus in Urbe*).—The grubs are the larvæ of the Celery Fly (*Tephritis onopordinis*), which have been very destructive this autumn, owing, probably, to the prolonged term of dry weather during September and October. As soon as we perceived the first few blisters we picked them off, and at once dusted the plants with soot; by repeating the application slightly about once a week we prevented the crop receiving serious injury. You had better remove the blistered parts and leave the Celery where it is, protecting it with straw and litter when frosts occur, as it will be very liable to be injured owing to the comparative absence of leaves. If you dig up the crop and lay it in a cellar the stems are almost certain to shrivel and to lose their crispness; at any rate, we do not advise you to dig it up before you find it actually decaying in the ground. If you grew the crop for sale we should say the sooner it was dug and sold the better.

REVE D'OR ROSE NOT FLOWERING (*Idem*).—We are not surprised that your Rose which was planted last year and cut down nearly to the ground this spring has not flowered; but you have no reason to be disappointed with the progress the plant has made. You treated it correctly, and it has made excellent growth, and next year will almost certainly afford you fine blooms. If the shoots are crowded thin them out at once, so as to expose those remaining to light and air. Do not shorten the principal shoots, except to keep them within the space required, and then, the wood being matured, they may be expected to produce flowers freely next summer.

OSAGE ORANGE CULTURE (*South American*).—The following extract from the *Prairie Farmer* will perhaps afford you the required information:—The plants are always raised from seed. Sow the seed in drills, having first soaked them in warm water for forty-eight hours, and place them thinly between damp cloths, where they may remain warm and moist, until indications of sprouting are seen. The time for sowing is immediately after corn-planting time, or after the soil becomes warm. The preparation of the seed by soaking and sprouting should commence two weeks earlier. The rows in which the seeds are to be planted should be 3 feet apart, and the seeds be sown about an inch apart in the row, and keep the plants entirely free from weeds. In the autumn cut the tops about 4 inches above the surface, and the roots about 8 inches below ground. Dig, and after sorting according to size, heel in the earth in a dry place, covering the tops with litter and earth to prevent freezing. In the spring they are to be planted in a properly prepared hedgerow, where they are to remain. Some growers tie loosely in small bundles of say fifty plants each, and setting upon their roots cover all with earth, tops and bottom. Heeling-in is preferable. The usual distance apart to plant in the hedgerow is about 10 to 12 inches. Pack the earth firmly about the roots, and deep enough, so when the earth settles the yellow portion will be entirely below ground, or about 2 inches deeper than they originally stood.

PRUNING VINES (*G. H.*).—If most of the leaves have fallen off the Vines and the wood is ripe you may prune them at once, so as to afford them all the rest possible before starting them.

PLANTING ANEMONES (*Idem*).—The Anemone requires a pure loamy soil well mixed with sand, such as sometimes is found on the sides of rivers naturally mixed with the sand. Choose a situation that is open, but sheltered from violent winds or strong twisting currents of air; then dig out the soil a foot or more, according as the situation is high or low; if high it may be dug out 3 or 4 inches deeper, but if low and wet a foot will be sufficient. Mix the soil with sand if it requires it, and fill in the bed again to within 6 inches of the level of the surface; then level it, and lay on it a thin covering of thoroughly decomposed hotbed manure or cow dung; the latter is to be preferred. Mix this well with the soil below. Upon this mixed enriched soil place as much of the pure sandy loam as will raise the bed an inch or two above the walk. No dung must be among this top stratum of soil, because dung causes the peculiar disease called mould to attack the bulbs that come in contact with it. The best season for planting is from about the middle of October to the first week in November; the bulbs then form roots before severe frosts set in. Should the planting be unavoidably delayed the bed must then be covered with fern or straw. Choose a time when the soil is moderately dry and the day fine. Draw drills across the bed 2 inches deep and 5 or 6 inches apart, and plant the tubers 5 inches apart in the rows. For choice varieties a thin layer of sand scattered under and around each tuber will be useful. As soon as the bed is planted cover the tubers with sandy loam from a basket or wheelbarrow. Take care that the tubers are placed the right side up by observing the side that has the old small fibres on it. That side place next to the bottom of the drill. When all are planted and covered up the right depth (2 inches) then level the surface with a garden rake.

NAMES OF FRUITS (*Connaught Subscriber*).—The Grapes are—1, Black Alicante; 2, Black Prince; and the Pear is Beurré d'Aremberg. (*G. W. Ayshire*).—1 and 3, Beurré Diel; 2, Beurré d'Aremberg; 4, Joséphine de Malines; 5, not known; 6, Gansel's Bergamot. (*F. Taylor*).—1, Warner's King; 2, Herefordshire Pearmain; 3, Tower of Glamis; 4, Winter Hawthornden; 5, Golden Nonpareil; 6, Braddick's Nonpareil. (*S. Skinner*).—Beurré Clairgeau.

NAMES OF PLANTS (*C. T. H.*).—1, Phymatodes glauca; 2, Onychium japonicum; 3, Athyrium filix-femina Frisellia. The numbers were off the others, but the large bright green frond we recognise as Scolopendrium vulgare multifidum. (*G. R.*).—This not being in flower we are unable to identify it. (*G. M.*).—Gordonia Lisanthos; increase by American seeds or by layers. (*W. W.*).—Scorzonera.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

STRAW AND ITS USAGE.

STRAW is often alluded to as a substance of but slight importance; but upon the home farm, where pasture and park lands usually predominate over the arable and straw-producing soils, it is a matter of great consequence, and in many districts of the kingdom it is become comparatively a very costly article. The

question is often discussed of straw having doubled in value within the last twenty-five years. The cause of this appears to us to be various. First, we find that the straw-producing area is greatly reduced; the increase of population and the extension of towns, factories, &c., have pushed the market gardens, &c., further into the country districts, and have encroached upon the land used for cereal produce. Again, the increase of land laid into pasture has been great during the past twenty years, and not only has the producing area been diminished, but an enormously increased demand for straw has sprung up in connection with trade and commerce, increased quantities are used for packing purposes, and tradesmen of nearly every grade now keep an advertising van for delivery of goods, and consequently a horse requiring straw for litter. These requirements are, however, quite separate from agricultural consumption and the ordinary usage of this article upon the home farm, and we may confidently look in the future to making it one of the most profitable articles for sale in the corn-producing districts; therefore upon the home farm we recommend that straw crops should be grown (where the proportion of ploughing land is small), as a preparatory crop for roots before mangold, Swedes, or turnips, and without prejudice to these crops. For instance, we know now upon a home farm of capital crops of mangolds drilled after a crop of rye, sown and cut for straw only, just after coming into ear, the straw being worth at least from £5 to £6 per acre, the quantity of straw being a question of manure only, because the preparation is much surer for a root crop than a long fallow. Upon many farms in different parts of the kingdom large quantities of the best straw are used for thatching farm buildings and cottages, which is a great mistake. We ought to look to our mineral productions to afford the means of covering farm buildings, &c., such as flagstone, slate, or tiles, instead of using the perishable produce of our arable soils for the purpose. It is notorious that the best and most valuable straw is generally used for thatching, as being best adapted and the most durable; it is, however, in some districts very costly. We were lately engaged in a question of repairs, and found that straw fit for thatching could only be obtained by paying £6 per ton for the article.

We will now refer to the production of straw upon the home farm. If it is to be used for thatching the corn should stand to be fully ripe, the straw will then become hard and glazed with silica; but in case it is required for use as a feeding material for cattle, it should be cut before the grain is ripe. This will be in favour of the grain also, because there is less loss by bretting or injury through bad weather. We will give the composition of straw as it is usually found on the farm, and cut at the usual time

	Wheat Straw.	Barley Straw.	Oat Straw.
Water	14.23	14.30	12.06
Flesh-forming matter	1.79	1.68	1.63
Respiratory and fatty matter	31.06	39.98	37.86
Woody fibre	45.45	39.80	43.80
Mineral matters (ash)	7.47	4.24	4.85
	100.00	100.00	100.00

In comparing these analyses with the feeding value of good meadow and field hay we find on the average gives sixty-three parts feeding value, whilst straw gives on the average of the three kinds, wheat, barley, and oats, forty parts feeding value. This is certainly a more favourable view of the value of straw than the ordinary use of it would lead us to suppose. In certain cases, however, straw is of still higher value, for instance in the case of cutting green for straw only; it would then have nearly the value of hay if ricked in a green state, like the value of wild oat hay so much in use in the prairie districts of America. The crop when cut green may be succeeded by mangolds or Swedish turnips; but a favourite plan of our own, pursued for many years, was to grow either winter oats or the white Canadian variety, both of which ripen a fortnight before the wheat crop, and by ploughing immediately after the oats were cut we usually secured the best common turnips. The oats, however, were cut very green for the purpose of feeding cattle with the straw, which

we always found better than hay for that purpose, and upon which subject Mr. Blundell of Southampton read a paper before the Royal Agricultural Society in 1862, giving his experience of and experiments upon straw feeding of thirty-seven head of bullocks during three years, which left a clear profit of 3s. 3d. per head per week, whereas the use of hay would have left only 3d. per week profit. But there is another view of this matter, because when cattle are fed upon straw they enjoy continuous good health, whereas hay often clogs and disorders the stomach; but we have never found them refuse their food when straw was the only fodder used. Still we find the case is now somewhat altered, owing to the relative value of straw and hay, for in many districts there is little or no difference in the value of the two articles, yet the advantage of straw prevails on account of the uniformity of the health of the fattening cattle. We find horses will do much better with straw chaff and corn mixed with pulped roots, either mangolds or carrots, and some farmers whom we know are now beginning to follow our plan and make it a rule to feed in this manner, either by displacing all the oats or a part of them according to the labour required of the horses, and in this way they may be kept in fine condition upon the home farm. The advantage in this method of horse-feeding is that they are induced to eat straw which they would refuse unless mixed with roots, and these roots consumed by displacing a portion of the corn usually given is in itself a profitable transaction. The feeding value of an acre of roots is equivalent to three acres of corn produce, because 3 cwt. of carrots or mangolds are equal in feeding value to one bushel of oats, taking for comparison a crop of oats at six quarters per acre, and a crop of carrots or mangolds at 21 tons per acre. Straw must also be considered almost a necessity in affording cleanliness and health to our animals, and, also in forming the basis of manure on the home farm. It is however, to be greatly economised in the stable or cattle pens, where the floor of the stalls is absorbent, hence the earth or burnt-lime bottom to the stalls requires far less straw to keep the animals clean and healthy than the ordinary brick or stone floor.

Various substitutes for straw may be found upon the home farm; ferns, rough grass in the plantations, rushes and patches of seeded grass in the pastures, may all be used to economise straw in littering the pens for cows, pigs, &c. Under the heading of "Straw" Dr. Voelcker gives the analysis of peas and beans, but we call it haulm; and although the analysis shows more feeding value in pea and bean haulm than straw of the cereals, yet bean haulm is a coarse and rough article, and cannot be brought into general use for feeding without being cut into chaff and mixed with other articles as cooked food; we therefore only use it upon the home farm for the bottom of corn and hay ricks, or place it at the bottom of cattle boxes as an absorbent for manure. Pea haulm when well secured we always set apart as good feeding material, especially as chaff in admixture with other feeding stuffs. Ricking and preservation of straw at the time of threshing is very important. It should be ricked and thatched with as much care and caution as hay, so that when required for use it may be cut out and carried to the homestead fresh and sweet from the rick. In the case of barley or oat straw with clover in it, it comes out better than when it is oftentimes stored in a barn mow, in which case it is often tainted by rats and mice. Refuse straw intended for litter may also be kept dry, but its abuse must be guarded against; for we often see ten or more tons of straw strewn over an open yard with only a few pigs and dairy cows to tread it down for manure, but upon farms where the tenant has liberty to sell straw this practice will soon die out. Again, upon some of the chalk hill farms there is the muckle fold, in which case the straw is spread over the land and the sheep tread it down in a shifting fold at night. This is the old-fashioned way of using straw when the tenant was compelled to consume or use it. This, however, will not now hold as a practice compared with straw sold and the money expended in artificial or town manures. No farm manager need now hesitate as to the outlay for manures with straw at the present high value, for not only will it pay to make the outlay on the home farm for the purpose of growing a full cereal crop, but beyond the ordinary cultivation of the land and its produce the value of the extra straw grown will pay for the manure irrespective of the increased quantity of grain, because we cannot generally obtain the highest produce of corn without we obtain a full crop of straw, subject, of course, to the yield consequent upon the variation of the seasons.

WORK ON THE HOME FARM.

Horse Labour is still chiefly required in preparing the land and drilling the wheat. It is usual to plough and press the clover lea ground before ploughing and sowing the fallow preparations upon all dry soils; yet such is the state of the weather, and it encourages the slug so much, that it is advisable to delay seeding the clover lea until the last week in November or first week in December. The slugs having been so numerous in the clovers during the whole summer they will be sure to commit serious ravages upon the young wheat plants as soon as they show above ground, unless the wheat is sown sufficiently late to have when it vegetates a chance of frost. We therefore advise the seeding of the

fallow ground first, whether it is after turnips fed off, or after peas or beans, because the slug is not so likely to injure the wheat where the land has been lately tilled and fallowed. We must again call to notice the advantage of using Down's Farmer's Friend as the best preparation for seed wheat, to prevent the growth of smut in the crop next harvest. The quantity required of seed wheat per acre is still a vexed question, and will probably continue so, as the soil and preparation as well as climate and the period of sowing must all influence the question as to quantity of seed. We therefore recommend a quantity, varying with the season, from two bushels to three bushels per acre. The early sowing of wheat for the purpose of saving seed is continually being agitated by Mr. Mechi and others. As, however, early sowing and thin seeding go hand in hand, we beg to observe that upon many farms the early sowing of wheat would cause much inconvenience and derangement of the usual mode of culture. For instance, if all the wheat were sown early, or planted in the month of September, how could any autumn cultivation for root crops the next season be effected? How could the various crops preparatory for wheat be removed, such as potatoes, turnips, mangolds, &c., which are in process of digging, storing, or feeding-off by sheep, &c., during the months of October and November? What is the advantage of saving a bushel of seed per acre, or even more than a bushel, as compared with the advantage of taking up in good seasons crops of potatoes, carrots, mangolds, &c., which are often more valuable than the wheat crop itself, although they are preparatory? and what is the saving of seed compared with the requirements of large flocks of sheep, and their benefit to the land as a preparation for the wheat crop? The advocates for thin seeding must not forget that they run the risk of blight in their crops, for no corn is so liable to blight as those which are called upon to tiller and branch out, and make damaging efforts to fill vacancies in the spring of the year.

There is no period of the year when the odd horse or horses will be more fully employed than now. In fact the work is now so pressing that it is difficult to say which demands the first attention. On the autumn fallows there may be still some couch and weeds to cart away to heap, there to rot for future use. Hedge trimmings may still be required to be carted away, particularly in fields where roots were growing, as the carts could not enter until the roots, such as mangolds, &c., were cleared away.

Hand Labour.—Manual labour will now be employed in spreading dung upon land intended for wheat, and also where there are water meadows the drowner, or person entrusted with the irrigation and its necessary labour, must now have the trenches scoured. The right principle in irrigation is not only to lead the water on to the land, so that it may flow with regularity over the whole surface, but also to give it the freest outlet after having served the purposes of flooding. Store cattle will now require some change from the pastures which are getting stale, and they may now be accommodated in yards and sheds at night, and there receive a moderate allowance of decorticated cotton cake and straw; and if it is required to advance them quickly, common turnips cut and placed in troughs in addition, and by no means forgetting a lump of rock salt accessible to all. The dairy cows, too, demand our attention; for after the middle of October the grass, if not short in quantity, becomes poor in feeding value; we therefore give them cabbages upon the pastures, and we find them do well without decreasing their milk. They must, however, soon be brought to the stalls at night time, and receive in addition to cabbages some sweet oat straw, as they will not pay for hay, especially those which are nearly or quite out of profit. The woodlands upon the home farm must now be looked to, any portion of the underwood becoming fit for sale or cutting this winter must be disposed of accordingly; and it is well that only some portion should be cut every year, particularly where it is desired to rear and retain a few pheasants, and also for furnishing with regularity spar and hurdle wood, &c., for use on the home farm.

RABBITS AND THEIR CONSTITUTIONAL DISORDERS.

THERE are many hereditary weaknesses which grow on Rabbits chiefly from neglect and unnatural treatment, and which not unfrequently descend to the next generation. It is as well to remember that one male will often spoil twenty or fifty litters and a hundred or two of young ones, so that it is very important to see that everything is right before introducing a fresh sire. When contemplating this fact it should also be borne in mind that so many of these complaints are doubled or trebled by inbreeding, because both parents are likely to be affected in the same way; therefore, strange Rabbits should be selected when possible.

Paralysis is a complaint that is often transmitted in the blood. In the first place it is most likely caused by an excess of damp in the hutch. If the wood or hutch is porous, so that the wet can sink in, a nasty effluvia rises and keeps the air polluted. If this is continued it causes several complaints, and ultimately paralysis. As soon as the disease takes any hold upon a Rabbit the animal

shows symptoms of great debility and even impotence, especially in the hinder quarters, which seem to be quite useless and can only be dragged about. Sometimes the disease extends towards the head. In this case it is more serious, and generally results in death. As the appetite is speedily affected great care must be taken to tempt the Rabbits by frequent changes of food, and a little extra green food as an aperient will sometimes do good. It is seldom that a Rabbit with this disease ever thoroughly recovers; indeed, we hardly think it advisable to try to cure any but show Rabbits, as they should never be allowed to breed after having been once thoroughly diseased. The complaint is very apt to appear in the next litter, and will be easily brought out by damp and badly-smelling hutches.

Rabbits have sometimes sluggish and diseased livers. The complaint is very bad, as it tends to destroy all the benefit derived from good food. It is generally classed among preventive diseases. This we hardly see. If a Rabbit has a good liver constitutionally it will take a good deal to affect it very much any way, but if it has a weak one, inherited from its parents, a very little carelessness will cause disease. The disease most common in kind seems to consist of a quantity of little insects, which stick to the liver. If the liver is healthy and strong they will not be very injurious, but if the liver is at all weak they soon get a hold upon it. A cure is almost impossible, except when the remedies are tried very early in the disease. Plenty of light and air are the very best remedies that can be prescribed, with plenty of good substantial food. If show Rabbits they may be preserved alive for some time by these means, but a cure is doubtful. As the complaint is liable to be transmitted Rabbits affected with it should never be allowed to breed, as if they do their litters are pretty sure to be tainted.

A bad affected blood thoroughly impregnated in the system is another unpleasant disease to which Rabbits are constitutionally liable. It is caused in the first instance by starvation of the blood, and by giving only food that does not produce strength. Hence it is very necessary to keep the Rabbits well attended to, as the complaint is exceedingly debilitating and destroys the Rabbit's value for breeding. It makes itself apparent in many ways. The eye loses its vigour and becomes pallid and humid in appearance. If the Rabbit gets a scratch the place immediately festers and discharges profusely, boils rise on the back and sides, and the hair consequently comes off. Sometimes these are so small as to be more like pimples, and they all discharge a little. If squeezed a good deal of blood and matter comes out, and seems to afford momentary relief. It is well to wash this off and not leave it on the skin, as it might cause fresh eruptions. The less food that is given the worse the blood seems to get. The eruptions should not be confounded with small boils, which are more the result of overfeeding. A little cooling food, chiefly herbs, will be found to prevent this, and quickly to cure it. Gatherings should be broken and washed out. Sore hocks are sometimes caused by the want of stamp in the blood. In this case the hocks swell very much, and if the hutch is rough or dirty the disease is increased. The remedy that is best is the addition of substantial food, with plenty of purgative food at intervals. Meal mashes mixed with potatoes are very strengthening, and may be recommended for this complaint. This disease transmits itself in breeding, and therefore affected animals should be kept separate till their death. Often the remedies may keep show Rabbits well for a short time, but the discharges are very weakening, and it is not often that a Rabbit lives very long after being seized with the complaint.

Another affection is that of the kidneys, which affects Rabbits that are kept in damp hutches. If there is no outlet for the wet to pass away, and it is allowed to accumulate, the effect upon the kidneys is very palpable. The urine that is passed is often red. The Rabbits when affected show signs of debility and ill health. Warmth and judicious diet will be found most likely to produce a cure; plenty of green food of a milky nature should be given, as well as ample supplies of corn and meal.

As Rabbits closely connected often have the same disease it is most important to avoid in-breeding.—G.F.T.A.

ARRIVAL OF NORTHERN BIRDS.

MOST of the northern birds due in the middle of October have arrived. All the summer migrants have gone except a few house swallows. The London bird-catchers have lately had large takes of the brown linnet, common redpoll, greenfinches, yellowhammers, siskins, goldfinches, and mountain or tree sparrows. The flights of birds arriving from the north are as follows:—Hawfinches, goldfinches, chaffinches, siskins, mountain sparrows, twites, brambling finches, bullfinches, brown linnets, woodlarks, redwings, blackbirds, thrushes, and stony redpolls. The stony redpoll has skipped these coasts for the last two or three years, but many have been taken during the past week. Ring-ousels have been very scarce this autumn. The northern larks, fieldfares, and snow buntings have not yet been seen, as it is still early in the season for them.

The various kinds of titmouse, such as the large-tit or ox-eye,

blue-tit, cole-tit, and marsh-tit, are very plentiful about the suburbs of London. Another class of birds common to this country is also plentiful, and may be seen by any ordinary observer about the borders of woodlands and copses near London. These are the nuthatch, little tree-creeper, common wren, the golden-crested wren, and long-tailed titmouse. All these birds frequent the same localities in the company of each other. They are especially fond of parts of the country where firs and yews abound. The last five birds do not seem to increase in numbers, and are never more plentiful one year than another; for the last thirty years there has been no noticeable increase in them. This is all the more remarkable, as these birds are very seldom trapped in nets, caught with birdlime, or killed by gunners. They are useless except as specimens for the cabinet.

The hooded or Royston crow has been noticed on the marshes below Gravesend. These birds are generally observed first at Flamborough Head, in Yorkshire. At Flamborough Head during the last few days many of our autumnal visitors have been noticed—namely, scores of blackbirds, thrushes, crested wrens, and owls. These owls were probably bred in the rocks in the vicinity of Flamborough. Flamborough Head is the great arrival station of many autumnal migratory birds proceeding south from Norway, Sweden, &c.

Woodcocks are also beginning to arrive at Flamborough. These birds subsist during the summer months on the larvæ of the mosquitoes and other insects that breed in the extensive marshes of Norway and Sweden. The moonlight nights and easterly winds during the last few days have been especially favourable for the arrival of birds from the north. At Flamborough the blue rock doves are also very plentiful. These birds are found nearly all the world over; they will not breed in captivity. Visitors to Rosherville, near London, may have noticed many pairs of these birds breeding about the cliffs in the gardens. At the present time the blue rocks are feeding on the stubbles, and their favourite food is the charlock seed. They do much good by eating up the seeds of this weed. These blue rocks must not be confounded with the blue rocks used for pigeon-shooting from the trap. Linnets and greenfinches also eat large quantities of charlock seed. This fact accounts for large numbers of these birds being seen on the stubble lands.

During the late foggy evenings numbers of the small common mouse-eared bat have been seen about the streets in the north part of London. It is difficult to know on what these bats are feeding, as there is very little insect food to be had, such as moths, &c.—(*Daily News*.)

VARIETIES.

It may be interesting to some of our bee-keeping readers to learn that a Hertfordshire Bee-keepers' Association is in process of formation. It was at first intended by the promoters to form an association for West Herts only, and during the past summer several meetings have been held with this object, whilst displays of bee-driving, &c., have been given at Harpenden, Rickmansworth, Latimer, and Great Berkhamstead at the shows of their horticultural and cottage garden societies. Prizes have also been offered to cottagers and others for the best supers of honey in wood, glass, or straw. By the advice, however, of the Bishop of the diocese the scope of the Association has been enlarged, and its operations will be extended to the whole of Hertfordshire instead of being confined to its western division only. The Earl of Verulam, the Lord Lieutenant of the county, has consented to be President of the Association; and the Bishop of St. Albans, the Earl of Clarendon, Earl Brownlow, Lord Ebury, and Lord Chesham have promised to be Vice-Presidents. Other names will shortly be added to the list, and a new vigorous Association will take its place amongst the Lincolnshire, Devon and Exeter, Dorsetshire, and other county associations already in existence.

—The official list of awards made to British exhibitors at the Paris Exhibition, including those for all kinds of live stock, has appeared very clearly and elaborately got up. H.R.H. the President of the British Commission has sent a copy of it to every juror not present to receive it at the distribution of prizes. A note is appended to the list of jurors to the effect that their services were entirely gratuitous.

—At the Tunbridge Wells Poultry Show a Carrier Pigeon belonging to Mr. Stephens was claimed for £100. We believe the purchaser was Mr. Hedley. We think that at least one bird of the same variety was last year sold for the same price.

—A MEETING was held on the 23rd inst. at the County and Borough Halls, Guildford, to inaugurate the newly-formed Surrey Columbarian Society. The President of the Society, Mr. O. E. Cresswell, took the chair; the Vice-president, the Rev. G. S. Davies of Charterhouse, the Hon. Secs. Messrs. Walker and Allen, and many local fanciers, were present. The Society will hold its first show at Guildford in December.

—We have before us a large number of schedules of shows to be held in the month of November. Among them, on November 6th and 7th, the Cambridge Show of Poultry, Pigeons,

and Cage Birds. We remember a very good show there about five years ago, and hope that this revived one may be well patronised. On the 22nd and 23rd of the month the Kilmarnock Show will take place. The classification is one of the most extended and complete we have ever seen save at the greatest national shows. There are 42 classes for Poultry, 35 for Pigeons, and 19 for Cage Birds, 9 for Rabbits, and 2 for Cats. The entries close on November 9th. The Norwich Show is fixed for the 21st, 22nd, and 23rd. The classification is, as in former years, very good. There are special cups and prizes for members of the Society. On the 27th and 28th a West Kent Show is advertised to be held at Bexley Heath; and on the same days the Show of the Rutland Agricultural Society at Oakham. This has long been a well-managed and popular institution. We regret to see that the pairs of hens so long seen there are no longer to appear, but single birds alone. Another poultry show will be held at Poole in January. It will be under the patronage and rules of the Poultry Club.

— WE are continually hearing evidence of the spread of the poultry and Pigeon fancy both in the Old and New Worlds. Some Pouters from the celebrated lofts of Mr. and Mrs. Holmes of Bath were lately exported to Austria, and last week some of Mr. Cresswell's Turbitts started from their temporary abode near Bagshot for Boston, U.S. America.

— DESERVING of special notice at the Clonmel Agricultural Show were specimens exhibited by Robert Cooke, Esq., of three cuttings of Italian rye grass, with the seed saved from the second and third; that saved from the first is generally worse than useless, as containing the seeds of weeds, &c.; that from the third crop was very inferior to the splendid sample saved from the second cutting. Many farmers were interested in seeing this marked distinction. The exhibition of other farm produce was very superior.

— THE largest farm in the world is probably that which has just been purchased by a New York Joint Stock Company in Northern New Mexico; it covers 250,000 acres, and will be used for cattle and sheep raising. A good start has already been made with five thousand improved American cattle and fifteen thousand Merino sheep.

— THE Duke of Sutherland has presented a milch cow, and allowed sufficient pasture land for its keeping, to every small tradesman on his Trentham estates.

— WE are requested to state that the Ipswich Poultry Show will take place early in January next, instead of as advertised, due notice of which will be given.

— IN the returns for the year 1877 the poultry in Ireland were enumerated in four classes. There are 751,809 turkeys, 2,240,399 geese, 2,653,070 ducks, and 7,920,805 ordinary fowl, making a total of 13,566,083, or 53,417 fewer than the very large number in the preceding year's return. It will be observed that there are three times as many geese as turkeys, but the proportion varies greatly in different parts. In Leinster and Ulster the turkeys are not very much less than half as many as the geese; in Munster they are not near a third the number of the geese; and in Connaught they are less than a fifth of the number of geese. In the counties of Down and Dublin the turkeys and geese are almost equal in number—41,991 turkeys and 43,326 geese, and 8872 turkeys and 8966 geese respectively. In the county of Meath the turkeys outnumber the geese, there being 22,659 of the former and only 19,819 of the latter. Ducks and ordinary fowl appear to be more evenly distributed; the former number about one in every five of the total poultry in Leinster and Connaught, one in six in Munster, and one in four in Ulster. Estimating the geese and turkeys at an average market price of 3s. each, and ducks and ordinary fowl at 2s. 6d. per pair, the poultry in Ireland at the enumeration in 1877 would represent a total value of £1,109,698.

— ACCORDING to the *Journal des Débats*, the number of horses in the principal countries of Europe is as follows:—Russia, 21,570,000; Germany, 3,352,000; Great Britain, 2,255,000; Hungary, 2,179,000; Austria, 1,367,000; and Turkey, 1,000,000. According to the same authority there are 9,504,000 horses in the United States; 4,000,000 in the Argentine Republic; 2,624,000 in Canada, and 1,600,000 in Uruguay.

UNPRODUCTIVE BEE'S EGGS—IVY HONEY.

AT page 287 of the current volume will be found a notice by me of a singular phenomenon which occurred here this autumn—namely, a young queen laying eggs during a period of six weeks which were unproductive.

I have now to add—though it does not lessen the curiosity of the fact above mentioned—that within the last fortnight this same queen has laid eggs which have produced grubs. A quantity of brood was found in various stages of development in large portions of two combs.

Can it be that this queen being unusually vigorous continued

laying eggs during September, the usual rest month of the year (in places like this where no honey is found in the fields), and that the bees destroyed them as fast as they were laid, tired as it were of the labours of nursing, while the queen laid on unheeding the fate of her eggs? It may be observed that the resumption of breeding was simultaneous with the commencement of an unusually good ivy honey season. My bees have been for several weeks as active in honey-gathering as in summer both early and late in the day. It is a sickly-tasted honey.—B. & W.

BEE-KEEPING.

THIS spring I had two straw hives; one of them was stocked with condemned bees that I bought last autumn, but they only quarter filled the hive with comb. I fed them this spring, but they would not swarm; for three weeks they hung outside the hive like a large swarm. On June 29th I put on a super; they began at once to fill it, but did not leave the outside. As I had no eke to put under I placed a flat-top hive under the full one. July 8th I took off the super with 20½ lbs. of beautiful honey-comb. On August 7th I drove the top hive into the bottom one, which was half full of comb. I obtained 30 lbs. of run honey—50½ lbs. in all. The other hive, which was 15 inches by 10, only sent off one swarm, which in due course I supered with an Epps's cocoa box. The stock hive I drove twenty-one days after it swarmed. From both hives I obtained upwards of 40 lbs. of honey. In all I made £5 10s. 6d., besides what we used. £1 I spent in sugar to feed with. I have £4 10s. 6d. in my pocket and three good hives of bees in my garden—not amiss for a start. I have no doubt the result would have been greater if the master of the straw hive had been at my elbow, as the master of the Stewarton apparently was at "J. R.'s." I have made many blunders, but practice makes perfect. I placed the brood comb from my best hive (there was a great quantity) into a small hive, and set it on top of the hive where the bees were, thinking they would hatch it out, but all the bees went up and took possession. I did not feed them for fear they should build comb. When the brood was hatched I drove them back to their proper hive. I was more successful with the other hive. I fastened a piece of board and bored some holes in it, put in some pegs thick enough to keep the combs at proper distance and upright like toast in a rack, and placed it under the hive. The bees have built their comb to it beautifully. At any time I can turn up the hive and take away the board and pegs now the comb is fast.

The hives are my own make, I never made any before nor saw any made. I have made one 16 inches by 10 with a moveable top, so that when I want to take the honey I can turn it on its crown, run a knife round the sides, lift it off leaving the combs fast to the crown. By running a knife between the comb and the crown I shall be able to secure every comb without breaking, what the "RENFREWSHIRE BEE-KEEPER" complains of so much at page 252. If his cross-sticks had been made properly they would not have damaged the comb. I made mine straight, round, and very much tapered, the end that stood out an inch was square. When you take hold of them with pincers give a twist; the stick then comes out without damage.—J. B., *S. Yorkshshire*.

STRENGTHENING STOCKS IN AUTUMN.

EVERYONE is agreed that it is of the first importance to strengthen stocks in autumn. Stocks so strengthened, and just in proportion as they are strengthened, will (all other things being equal) be the first to breed in the spring, the first to swarm or to fill supers as the case may be, and will generally prove the most profitable in every respect. To secure this desirable object is the aim of all bee-masters; and accordingly at this time of year, when the ivy blossoms wake up the bees everywhere and stimulate the queens to recommence egg-laying, every effort is made to increase and prolong the stimulus in this direction. Hence more or less continuous feeding is going on in all apiaries. Hence the joining of weak populations, and the saving of bees from doomed stocks for uniting with those that are being strengthened for future use.

These several plans are all excellent in their turn. They are in full use here at this present moment. But this autumn we are trying another plan, which I recommend to the notice of the apiarian readers of this Journal: it can only be conveniently tried by bar-framists whose bars are all of the same size, as they ought to be in every apiary. Our new plan consists in the saving of condemned bees and utilising them by putting them temporarily into empty bar-framed hives, two or three lots of bees together in each hive, and stimulating them to breed in empty worker combs previously adapted to the frames. At the end of twenty days, or a little earlier, the frames will be taken out, and such as are filled with brood will be transferred to the hives which it is desired to strengthen for the coming year. It is obvious how great an addition to the youthful population of a hive may be made in this way. It is far better than merely adding the populations of doomed stocks, among which are sure to be found numbers of

more or less old and moribund bees. Care should be taken after a time to remove these temporarily utilised frames should they happen to be less regular than those in whose place they were substituted. This should be done as soon as the young bees have been hatched out of them, then all can be finally arranged for the winter.

By this plan it is obvious that very large populations of late-hatched bees can be secured throughout the apiary at a trifling cost. All that need be given of sugar syrup is just that which will suffice to keep up the stimulus necessary to encourage the queen to breed. Should any of it have been stored in the combs utilised for breeding, it can be given to the bees at any time by simply arranging it in a box set superwise over any stock that may require it.

The present autumn seems to be singularly favourable to the development of late brood, owing to the great quantity of ivy blossom, which is expanding quite a fortnight earlier than usual, owing also to the summer-like warmth of the weather.—B. & W.

EXTRACTING HONEY FROM COMBS.

ONE of your correspondents, "IGNORANCE," asks, "What is the most improved method of extracting honey from the combs?" This is rather difficult to answer, because he does not say whether his object is to save the combs for future use or merely to run the honey. If the latter be his object he will find an excellent description in "Bee-keeping for the Many" at page 29. In addition to what is there said I would only advise him to cut away every atom of bee bread and brood comb before he commences to cut up the honeycomb.

If his object be to preserve the comb entire, of course the "slinger" is the only thing to use. Failing this he may do as I have done this autumn with my bar-frames—that is, slice the lids off the combs with a sharp knife, but carefully, and then proceed to scrape down the honey on both sides of the comb, leaving the base of the cells as little injured as possible. This ought properly to be done in warm weather. If the comb is pretty tough most of the honey will run off in a few hours without seriously injuring the fabric—the comb being stood upright over a dish. This done, in my own case I have given the comb to my bees to clear away; and I have some now which the bees have utilised in a hive I have been transferring. They have succeeded in very neatly reforming and refilling the cells from their foundation. I doubt the possibility of treating in this way any fresh honeycomb out of hives without bar-frames, as the combs would infallibly break up.—B. & W.

OUR LETTER BOX.

COCKEREL HAVING BRONCHITIS (*H. Smith*).—Give him bread soaked in ale twice daily until recovered.

CLEANING BIRD SEED (*M. H.*).—The best way to clean Canary seed is to three-palls it a cotton stocking, and with the end tied up exercise yourself for a few minutes by holding the ends of the stocking in each hand, and with an up-and-down motion shake well the seed. Afterwards rid the seed from dust and chaff with the aid of a fine sieve, at the same time converting your mouth into a makeshift winnowing machine.

PARAKEET UNHEALTHY (*E. W.*).—As your Parakeet is suffering from an attack of diarrhoea you may now discontinue the fruit diet. Rust in the food or two or three rusted nails in the water will act beneficially. You have done all you need to do in piercing the swollen feet to let out the humour. Occasionally bathe the bird's feet with warm water, and when dry anoint them with the oil of almonds. Do not use sawdust. Lower the perches to within a couple of inches of the cage floor, upon which place some clean moss or soft hay. As the bird gains strength raise the perches.

PRESERVING EGGS (*G. S. B.*).—We cannot tell why the eggs painted with linseed oil proved bad. Employ eggs quite fresh. We have had eggs that have been kept twelve months, and then perfectly fit for any culinary purpose. We generally use a glazed breadpan. The bottom should be covered with slaked lime wetted to a consistence that will allow anything put in it to stand upright. The bottom layers of lime will be 2 inches thick. The eggs are stuck in this small end downwards close together, but not touching. When the bottom layer is full, then a fresh mixture of slaked lime is poured till thick enough for the eggs to stand up in it, and so on till the pan is full. The eggs should be perfectly sound in shell, not cracked or in any way injured, and they must not touch each other.

CANE.—"J. B." desires to know where he could obtain cane for making hives.

COVERING STEWARTON HIVES (*G. B. B.*).—Heavy wooded hives are an exploded idea, the lighter being every way better and more porous. All hives whether of wood or straw must be carefully protected from the weather by some good external covering, such as a bee house, straw hackle, or wooden cover, for each stock singly, in keeping with the taste or means of the bee-keeper. My colonies are on single pedestals protected by covers of square and octagon form; these are of wood, three-quarters of an inch thick, 18 inches wide, by 27 inches high at the eaves. The body and top are alike moveable, the last named covered with thin zinc surmounted at the apex by a turned vase, well painted stone colour. These covers are thoroughly useful as well as ornamental. If slides project 1½ inch to draw by, and are made to work very easy at the start, they give no trouble afterwards; if cut too short and fit tightly they require a pair of pincers to draw them. The sun's rays in summer, and a heated smoothing iron at other times, are said to be sufficient to soften any amount of propolis, but after twenty years' experience I have never had occasion to employ either.—A RENFREWSHIRE BEE-KEEPER.

BEES (*R. A. M. J.*).—Bees would no doubt do well in a hayloft, provided good pasturage was afforded outdoors, supplemented by artificial feeding as required.

CHLOROFORMING BEES (*J. Salter*).—If you can cover and surround the strong colony of bees which are under the plastering of your house with any kind of strong cloth slightly damped you may both save the bees and take their honey by the use of chloroform. The nest being 14 feet from the ground is the greatest difficulty. First go up the ladder with some smoking cotton rags in your hand, and if the bees be disturbed apply the smoke and master them till you see how the cloth can be fixed, then fix the cloth as closely around the bees as you can with a taceup saucer inside. When this is done pour an ounce or two of chloroform into the saucer. The chloroform will act instantaneously and cause the bees to make a great buzzing noise. As soon as the noise subsides the bees will be found in the cloth, and should be speedily hived, and all the combs promptly cut down and removed. An expert in bee management could easily use the combs from the bees without the use of chloroform, and have them afterwards.

TOMATO SAUCE (*Rus in Urbe*).—Stew a dozen large tomatoes with Cayenne pepper and salt until they become like a marmalade. Pass them through a sieve to remove the seeds, and stir until it is of the consistency of very thick cream, then add a half pint of nice broth and a little butter; or if you have no broth a little warm water, and 1½ oz. of butter, with two table-spoonfuls of grated biscuit, or bread may be stirred in just before sending to table. In seasoning the same use very little pepper. It will be a nice accompaniment to beefsteak or cold roast beef.

METEOROLOGICAL OBSERVATIONS.

REMARKS.

23rd.—Fine bright morning, shower at 2.50 P.M.; fine afternoon, damp evening. Air temperature down to 32°, and a little snow.

24th.—Wet morning, heavy rain at 11 to 11.15 A.M. with squall of wind; fine bright afternoon; cold starlight night.

25th.—Fine, bright, cool day; beautiful starlight evening.

26th.—Heavy showers during the morning; fine afternoon, but stormy-looking sky, and windy; starlight evening.

27th.—Very fine fresh autumnal day.

28th.—White frost in early morning, shower at 11.30 A.M., and slight shower 2.15 P.M.; fine afternoon, with sunshine; wind rather high in evening.

29th.—Clear cold day, bright sun at intervals; solar halo at noon; starlight night.

Seasonably cool weather seems to have set in, but although there have been traces of white frost on metal surfaces, none has yet been formed on grass, and the air temperature has not yet fallen below 56°.—G. J. SYMONS.

COVENT GARDEN MARKET.—OCTOBER 30.

THE only feature in our Market has been the steady fall in Kent Cobs, there being a disinclination on the part of buyers to do much business at present rates.

From observations taken near London during forty-three years, the average day temperature of the week is 59.9°; and its night temperature 34.5°.

ABOUT POTATOES.

LATE Potatoes in this neighbourhood are a very light crop of small tubers: it has been again abundantly proved that early-ripening sorts are the most profitable to grow. I have fortunately grown nothing in quantity but Myatt's Prolific, with the true old Ashleaf for the earliest. None of the so-called improved varieties are as early by a fortnight as this, although several of them are better croppers. I have no idea how long the stock of the old Ashleaf has been here, perhaps half a century, but it never varies and never shows a flower. This season it produced an excellent crop, quite as heavy as Myatt's, but that is an unusual occurrence; it generally produces little more than half that quantity. Part of the seed of Myatt's Prolific was home-grown and part was bought from a totally different soil, but there was no appreciable difference at taking-up time—all were good alike for the season, averaging considerably more than two bushels to a perch. In addition to the seed coming from two sources, my own was taken up early in July last year before it was anything like ripe, and indeed some of it was not fully grown, while the bought seed was not lifted till the end of September.

I cannot argue the point with those who recommend changing of seed, but I can speak from a limited experience and say that the benefits arising from changing of seed here are invisible, and I am inclined to think non-existent. I do not say that changing is never beneficial; I have heard and read enough to almost convince me that it is sometimes productive of good results. There are probably some soils where the Potato deteriorates and would in course of time become almost worthless, and in that case it may be necessary to obtain a fresh stock frequently from a more congenial soil. But supposing A to possess a soil where he finds it necessary to have frequent changes of seed, and B to have a soil which continually produces a fair average quantity and quality of the good standard kinds from the same stocks, A may obtain seed from B, and the results the first season may be extraordinary; but I think B would not be likely to have such results with seed obtained from A. Part of this statement is of course little more than theory, and I should be glad to learn if in any mutual exchange of seed both parties claim to see an advantage. It will not surprise anyone after this statement if I say that in many cases more good may be done by selecting one's own seed and taking the greatest care of it than can be done by exchanging, for in the latter case the selecting of seed, which is a very important matter, is not likely to be done at all times so carefully. This does not apply to new or foreign sorts, for in some cases of new, or reputed new, varieties the characters are not anything like fixed, and some of the American Potatoes do not retain their good qualities long after leaving their native country.

As I said above, the selecting of seed is a very important matter. It is a mistaken economy to eat all the best tubers and save those that are small and misshapen for seed; eat

all the biggest if you like, and the smallest too if you can persuade anyone to cook them, but medium-sized good-shaped tubers should always be taken the greatest care of, laying them out singly soon after they are lifted; especially is this necessary with the kidney-shaped kinds, and they only take up half the room for storing this way that round kinds do. If they ever make growth which has to be rubbed off it is the best economy to give them at once to the pigs.

I should like to ask those who are qualified to answer, What is the object of Potato exhibitions, and are they likely to produce good results or the reverse? What are the principal points in judging Potatoes? Is there anything besides the appearance of the few selected tubers taken from nobody knows how much ground to guide the judges when dealing with sorts with which they are unacquainted? I know some people suppose that rough skins, white flesh, good shape, and shallow eyes are some of the points to look after; but the first and second are misleading, and the third and fourth are often more than counterbalanced by faults only known to those who dig and eat them. Is there anything else to guide us distant countrymen supposing we are called on to adjudicate in some great Potato tournament? The few dishes we have at our country shows are sufficiently puzzling; even the cooked tubers are cold when judged, and consequently have to be estimated principally by appearance. I would cheerfully undertake to act as censor on a couple of dozen dishes fresh cooked and hot, although even then it would be difficult to say how much credit belonged to the cook and how much to the tuber; but collections of known and unknown raw Potatoes are at present a puzzler. Who will enlighten me?—WILLIAM TAYLOR.

TEA AND NOISETTE ROSES UNDER DIFFICULTIES.

In your number of the 3rd of October "HEREFORDSHIRE INCUMBENT" draws attention to the difficulties I formerly experienced in growing Teas and Noisettes in an unfavourable atmosphere and an unsuitable soil, and he alludes to the improbability of my being able to exhibit them from such a locality. Now it is an unfortunate fact that the reverend rosarian's remarks are substantially correct. At one time I had two gardens both in close proximity to iron foundries and subject to the injurious influence of their sulphurous fumes, no clearer evidence of which can be had than the tendency in such a situation of blue Delphiniums, Anchusas, Myosotis, and other blue flowers to assume a reddish or purplish tint, when the same varieties grown away from such influence, but otherwise under similar conditions, retain their natural brilliant blues. The soil of both gardens consisted of a rich shallow and light artificial humus on a rubbly limestone subsoil, and much of that material being integrated with the surface. The situation was on a southern slope, and the summer sun hot and the soil forcing; but with this I had, in addition to the cold spring winds of the east of England, which usually allow but one good crop of fruit on the average in seven years, the full effect of the malaria and miasma from a spongy

meadow, alike injurious to man, quadrupeds, and plants; it was therefore hardly to be wondered at that neither Teas, Noisettes, nor the more delicate Hybrid Perpetuals should appear largely in my exhibition stands. Experience, however, taught me much and enabled me partially to overcome these apparently insurmountable obstacles; and although I was never able to counterfeit the late amiable Rev. Geo. Arkwright's wax-like shell-built Souvenir d'un Ami, Mr. Cant's famous La Boule d'Or, or the Rev. E. N. Pochin's massive and deep golden Maréchal Niel, and as he showed in his first forty-eight at Grantham (I believe in 1872), and which is only justice to him to say was one of the best blooms in the best stand ever exhibited by an amateur, as Messrs. Gayter and Merryweather will, I am sure, confirm me—I did eventually succeed in securing very respectable show blooms, and for some years successively at the York Shows in June I carried off the first prizes for Teas and light Roses. That this success, however, was not obtained except at the cost of much labour and the yearly deaths of a whole army of floral martyrs I am free to admit, but at the end of fifteen years there was a remanet of other varieties whose health and vigour constituted a valuable testimony to their powers of endurance under such adverse circumstances; I cannot, therefore, do better than enumerate them. The older varieties being Céline Forestier, Gloire de Dijon, Cloth of Gold, Lamarque, La Boule d'Or, Maréchal Niel, Safrano, Solfaterre, Triomphe de Rennes, Alba Rosea, Devoniensis, Rubens, President, America, La Pactole, Bougere, and Madame Falcot; and of the more recent sorts best able to brave the defects of soil, situation, and climate I found Rêve d'Or, Belle Lyonnaise, Madame Berard, Bouquet d'Or, Souvenir de Paul Neyron, Madame Hippolyte Jamain, Catherine Mermet, Marie Van Houtte, Anna Ollivier, Marie Arnaud, Marcelin Roda, Comtesse Nadaillac, Madame Caroline Kuster, Climbing Devoniensis, and lastly, as a doubtful but necessary member of the family, and which I consider to be one of the best, if not the very best, Rose ever raised—Cheshunt Hybrid, and yet this Rose when first exhibited by Mr. George Paul at the British Association's Horticultural Show at Nottingham, like La France, was only captivating by its singularity; but admirers of the Rose are liable to variation of taste as well as fashion in regard to their pets.

The more delicate sorts I could only keep up by continuously working fresh stock on the Briar, as I never found Teas to survive more than about two years on the Manetti and on their own roots. The propagation of weak growers is neither a rapid nor useful process. The cause of death of the martyrs in most cases arose from the injuries sustained by the very early growth caused by the forcing character of the soil, as, notwithstanding any amount of temporary shelter, the young growth was sure to be checked and sometimes repeatedly by the frosts of March, April, and May. A good covering for tender Roses is the common Bracken, or better still, the dry haulm of garden Peas loosely tucked in between the branches, tying only where absolutely necessary; this in a mild season can with advantage be removed and quickly replaced in case of a sudden decrease of temperature. For growing Teas and Noisettes for exhibition a wall or fence from 4 to 5 feet in height with north and south aspect is desirable, the Roses to be planted on each side and alternately as dwarfs on their own roots and standards or half-standards on the Briar about 3 feet apart, the plants to be left unpruned, and the vigorous shoots when long enough to be bent back and loosely trained over the wall. By this means both sides of the fence will be well covered, and blooms may be had either from dwarfs or standards and from one side of the wall or the other during a very protracted exhibition season, and the shade and shelter afforded by the overhanging branches will protect the blooms and heighten the colours.

Such sorts as Cloth of Gold, Maréchal Niel, La Boule d'Or, and L'Enfant Trouvé will do well worked on a strong old Banksian or Fortune's White, or even an established China or Boursault, which should be allowed to run wild and overhang at the top, so as to afford shade and shelter for the blooms, the importance of which in growing Maréchal Niel in its true form and colour cannot be over-estimated, and I have a suspicion forms at least one of the means of the Rev. E. N. Pochin's success in obtaining the orthodox pure golden colour which his glorious blooms almost constantly show. It is, however, certain that wherever there is a want of foliage (and the Maréchal especially in early spring is particularly defective in this respect) the colour of the blooms is invariably washy and faded. A remedy for this want can be partially supplied by allowing the shoots to ramble amongst the foliage of a Vine,

Pear, Plum, Fig, or other fruit tree on a wall, or to train the branches horizontally under a projecting coping or the eaves of a building, and the advantage of, and I might say the necessity for shade and shelter will be apparent; but the full and best remedy is supplied by the foliage of the stock, especially when the Banksian is employed for the purpose. These remarks apply also to a considerable extent to Cloth of Gold, or, as it is termed on the continent and in Jersey, "Chromatella," which, so far as I have observed, is one and the same variety. The growth of Cloth of Gold, as the Banksian, when the knife is not unsheathed and a liberal treatment is observed, will be marvellous. Such a dislike has this variety to surgery that I have heard it stated if the gardener approaches Cloth of Gold with a knife in his pocket it will not bloom, and this dislike to knife and scissors is exhibited in little less degree by the Maréchal and most other Teas and Noisettes, and the only pruning they require is the removal of unhealthy overaged wood.—T. LAXTON, *Bedford*.

HOW I GROW LILY OF THE VALLEY AND FORCE IT.

I HAVE just been examining our stock of Lily of the Valley grown for forcing, and find the crowns extra strong and forward. As the system I pursue in the cultivation of this esteemed flower is different from the means generally employed for the production of its flowers out of season, and the results better than one commonly finds, a detailed account of how our plants are treated may be acceptable to those of your readers desirous of having forced Lily of the Valley at its best.

Suppose a commencement is made from the present time when the plants have finished their annual growth and are merely waiting to be introduced into a growing temperature to yield their crop of flowers and foliage, and make thereafter another season's growth. The entire stock of plants will shortly be removed from their present position, when they are plunged in a border facing the south and placed close to the wall of a stove, where, with the addition of a few mats thrown over them during severe frosts, they are safe from harm at the roots. Many of the plants have so filled the pots with roots as to have forced themselves above the level of the pot rims. All such are now transferred into pots just a little larger, so that water may be more efficiently applied. The surface of any of those that require levelling is also done now. The earliest forced batches of the preceding season are marked "first forced," "second forced," "third forced," and "fourth forced," and it is from these that the earliest forced flowers of the current year are produced, as they are found to be capable of being brought into flower quicker than are those which had not been started so early the previous season.

Various ways have been tried to bring on the earliest lots, but none with such good results as placing the pots underneath the stage of a forcing pit, and keeping them covered with straw until the buds have pushed an inch or two. They require to be gradually brought to bear the full light. As the flowers commence opening the plants are removed to a cooler structure in order to render them as hardy as possible and capable of enduring in rooms, or when cut. Those that are sent to the house are sent when the greater portion of the spikes have many flowers unopened. In this way the time they last is lengthened by several days, a matter of some importance when somewhere about twenty large and small plants are expected continually in the house during the first four months of the year. When the plants go out of bloom they are placed in a growing temperature, and are kept growing under glass until the weather is warm enough in May to place them outdoors. The later batches are brought on in moderately heated structures, and do not require at any time to be subjected to a forcing temperature.

About this time any plants requiring larger pots are re-potted. A good loam is used. Fresh potfalls are formed at this season; clumps corresponding to the size of pots to be filled being lifted, potted-up, and kept with the other plants over the winter. The size of pot used varies considerably, the greater number of plants being in 9 and 10-inch pots, though both larger and smaller pots are employed.

About the beginning of June the plants are transferred to their summer quarters, a position on a sunny border, where the pots are plunged up to the rims. They are placed on smaller to secure a clear outlet for drainage water. Here they are supplied with liberal waterings of weak liquid manure throughout the summer; during winter and the forcing season pure

water alone being given. From one year's end to the other the soil is kept in a moist condition. When in full flower in rooms, saucers to fit the pots are used and kept full of water.

These are the essential points I observe in cultivating Lily of the Valley—much trouble, many of your readers will doubtless think. Well, there is more trouble necessarily involved than in growing continental produce, or in stowing the pots away in some corner where they may be sometimes remembered, oftener forgotten. But then the potfulls of charming flowers and foliage I have every season to present my employers with would fully compensate for much more trouble than is incurred in their cultivation, and I am certain anyone who may be induced to try the mode of cultivation just explained and give the plants attention, will never regret any little extra work that may be thereby imposed on them.—R. P. BROTHERSTON, *Tynningham*.

GRAPES NOT COLOURING.

WITH regard to the note (page 298) made by "A KITCHEN GARDENER" on the want of finish in Grapes this year, allow me to say that my remarks in the "Gardener" applied to five or six counties besides East Lothian, in which I had seen badly finished Grapes. At the grand show of fruit in Edinburgh there was a great want of finish in many of the Grapes. Thick-skinned Grapes, such as Lady Downe's and Alicante, have coloured well, but it is notorious that some of our best Grape-growers did not exhibit this autumn, and that in one instance where some magnificent specimens were shown these had been ripened some ten weeks before being shown. Another evidence of the bad effects of over-much heat I find in the number of rusty berries amongst white Muscats. I believe Mr. Douglas of Loxford Hall cured this tendency in Muscats to rust when ripening by increasing the ventilation.

I am starting late Grapes earlier every year, and in localities like this, where there is the chance of having the Grapes cooked into sweetness now and again, a still earlier date for starting and ripening must be instituted. Grapes ripened in July keep in excellent order till the following March or April: and as Lady Downe's, the latest keeping of Grapes, is not affected as regards ripening by over-much heat, we must make a point of getting such fine late Grapes as Gros Guillaume, Calabrian Raisin, Royal Vineyard, Gros Colman, Black and White Muscat of Alexandria, and perhaps Mrs. Pearson, ripened in July. The only Grapes I expect to keep well this season are Lady Downe's and some Muscat of Alexandria ripened in that month and the beginning of August.—R. P. B.

MANETTI VERSUS SEEDLING BRIAR.

FIRST, the Manetti does not produce suckers like the Dog Rose, but it emits a quantity of shoots beneath the neck or collar.

Secondly, the Dog Rose produces suckers in abundance, which are more easily discerned by the inexperienced than shoots on Manetti.

Thirdly, the Manetti is the best stock for most Roses; it will thrive well on nearly all soils, but especially on poor or sandy soils if heavy manures (cow or pig) are added.

The above notes are written from practical experience, for being in the trade I have had to contend with Manetti shoots the same as have other growers. But why? Because I was in the habit of trusting careless hands to make the cuttings for stocks. Now I pass every cutting through my own hands or some other experienced persons, who will allow no eye however small to escape cutting out, and now as a consequence I am scarcely ever bothered with the Manetti throwing up a shoot.

How is it the Manetti has got into such disrepute? Because nurserymen or trade growers will not always carefully disbud the stocks that are sent out. They say it does not pay to disbud when Roses are so cheap and labour so dear; therefore many Roses when sold linger awhile and then in course of time are completely smothered by the stock: hence so many fine Manetti bushes (not Rose trees) are seen in different parts of the country, the owners waiting in vain for beautiful flowers and healthy glossy foliage.

The Manetti is a fine foster-parent (nothing more), for a Rose worked on that stock should be on its own roots the second season after planting, which is generally the case, provided it has been completely buried below the worked part, say 2 or 3 inches. Unfortunately Roses are not always planted

properly; the collar is often left bare, and if there is an undisbudded eye on the stock it is sure to assert its supremacy over the Rose.

Mr. Prince, the champion of the seedling Briar, tells us in his Rose list that how he accounts for his Roses doing so well is because he can change the soil at intervals, having plenty of fresh land at his disposal. Now I venture to say we can all grow Roses either on one stock or other well if we had the same facilities, but unfortunately we have not. Roses grown on fresh land would hardly need manure. We feel thankful if we can get hold of a little decayed turf now and then. How happy ought a man to be who can get plenty!

Here I should like to ask a few questions with regard to Roses on seedling stocks. Must rows on seedling stocks be planted above or below the worked part? If the worked part is left exposed how will a season like 1860 affect it? Will the plants be killed down to the ground, as ours were that year? if so, they cannot be regarded as the best stocks for the propagation of Roses. The Dog Briar never thrives well on sandy or light soils, a strong soil being its natural habitat. I do think the seedling Briar is a good stock for Tea Roses, as also is the Dog Briar raised from cuttings; but they should be disbudded like Manetti, which would not be so easily accomplished with seedlings.

The Manetti if planted deep will be safe from the severest frost, for if cut down to the ground line it would spring up more vigorous than before.—W. C. A.

I SHOULD like to take this opportunity of corroborating my friend Mr. Peach's theory that the Manetti stock when properly disbudded does not fling out true suckers or runners like the Briar undoubtedly does. I bought from my neighbour at King's Acre last autumn some eight dozen of Tea and Noisette Roses in pots, including among others all the varieties mentioned in my list published on page 309. I wintered the lot in cold frames under an east wall, occasionally watering the plants with weak liquid manure. When planted out in the ground in spring I found that in the case of two plants only was there any trace whatever of Manetti shoots growing, and these in a very weak state; and I venture to state that where special care is taken (as generally is the case with pot Roses) in disbudding, there is no danger of any overgrowth from so-called suckers with the Manetti.

It is also interesting to notice as a matter of fact that I find at the present time only one among the lot of Teas and Noisettes I have mentioned—though budded on the Manetti, and many of the varieties undoubtedly delicate in habit and dwarf in growth—that has failed to grow healthily and does not promise, with the good start they have got, to hold their own in their rough foster-mother's embrace, though I am aware my experience is in this respect contrary to that of most of my brother rosarians.—HEREFORDSHIRE INCUMBENT.

KYO LEEK CLUB.

THE above Club held their first annual Exhibition of Leeks on the 26th ult. in the large room of the Earl Grey Inn, Kyo. This Club is composed this year of forty-three members, each contributing 3s. 3d. per year in monthly payments of 8d. each. The members are principally miners; and each having to exhibit three Leeks *bona fide* their own growth, which rule is most zealously and strictly carried out, it creates a vast amount of interest in the growing of this useful vegetable in the district, which embraces a two-miles radius of the Earl Grey Inn; and the results show that the pitman gives his attention to something more than the proverbial bull dog. There are no better vegetable growers than the north country miners when situation and means are taken into consideration, one of the successful competitors living at an altitude of 980 feet above the level of the sea and exposed to frost and snow till the latter part of April.

As may be expected, the task of the Judges—Mr. J. Robinson of Shotley Bridge, and Mr. R. Shield of Swalwell—was no sinecure, as there was some keen competition among the thirty-nine exhibitors. The first-prize trio were a fine level lot with 10 inches of blanch and $5\frac{1}{2}$ in circumference. The second were about the same circumference, but half an inch shorter. The third were shorter again by an inch, but were 6 inches in circumference but not quite white.

After the Judges had performed their task the room was thrown open to visitors at a charge of 3d. each, of which upwards of a hundred availed themselves of the opportunity of seeing the Exhibition. The prizes consisted of various useful articles for gardening and household purposes, varying in value from 16s. down to 1s. 6d. Twenty-six exhibitors received prizes for superior

produce, each winner taking the article he liked best in rotation as placed by the Judges; and two were awarded special prizes of a quarter of a pound of tobacco each for the poorest stands of Leeks in the Show.—J. ROBINSON, *Dipton Colliery, Lintz Green, Honorary Secretary.*

[We publish the above report with pleasure, and compliment the colliers on spending their leisure hours so worthily.—EDS.]

ABOUT VINES.—No. 2.

In continuing my jottings about Vines I shall proceed with a plain statement of my own doings, and to make them the more useful to amateurs I shall certainly not neglect to particularise all the failures I have met with. To be apprised of the vicinity of danger I hold to be of more value than to be taught the road to success.

Here it may be well to explain, as I have been taught by a neighbouring mining engineer, the ground I occupy is the ancient watercourse of the Wear that now runs by it, and the soil being shored-up by the many floods of past ages accounts for it being of quite a different nature at short distances. Where my first vinery stands the subsoil is a mixture of clay, gravel, and sand; whereas where my second stands it is pure sand, which I am told is 100 feet in depth. This will partly explain the reason of my forming the two borders in different ways, the field being all fine old turf.

When commencing to form the roads and making preparations to build my first proceeding was to take the first spit from all paths, foundations, and the space my house was to occupy, and then to store it in the handiest spot for the borders. The next proceeding was to provide ample fall for drainage. I did not wish to raise my vinery an inch more than was necessary, but I made sure not to have the border stagnant. The place chosen for the border unfortunately fell 3 feet to the north-east. To surmount this difficulty I built a 21-inch stone wall 3 feet above the surface at the lowest end, and the top of this stone foundation formed the surface level after the border was completed. The good soil was first wheeled out from the whole space, and next the subsoil was carted out to fill-up the different paths from whence we had already taken the good soil. After a fall of 6 inches had been secured from back to front the bottom was thinly spread over with Portland cement, it being mixed with two parts of sharp sand. As soon as it was sufficiently set to allow being wheeled over by the aid of battens, stones and lime rubbish was spread over about 6 inches thick, a sufficient quantity having previously been screened to take out the smaller rubbish which was afterwards mixed with the border. The next proceeding was to cover the whole carefully with fresh-cut sods, the grass down. After this the border inside and out was filled up to its proper height with turfy soil. Inside, and of the portion of the border outside then made, there is 400 cubic yards, as the turf was laid a yard thick. To the soil was added about twenty loads of cow manure and half a ton of bones; the latter being kept handy a few were thrown into each barrow. In the report of my place I noticed that the bones were printed stones, and it appears I had neglected to mention to Mr. Wright the cow manure; the fact is, the quantity used was so small that I might treat it rather lightly. The front wall is 9-inch pillars with 2-feet arches the whole length, the under side of the arch being 6 inches below the surface of the border.

My second border received about the same quantity of manure, but no bones, and I only made the inside border 6 feet wide. The back part being intended for Peaches, I only added a little turf to what there was without disturbing the subsoil. The bottom being sand, I dispensed with artificial drainage entirely. I shall next notice the first year's growth of the Vines and the treatment they received.—JOSEPH WITHERSPOON, *Red Rose Vineries, Chester-le-Street.*

TROPÆOLUM TUBEROSUM.

I PURCHASED in 1877 from Messrs. Hurst & Son, Leadenhall Street, three small tubers of *Tropæolum tuberosum*, each about the size of a Cobnut. They thrived and blossomed well. On digging them up I found about 2 lbs. of tubers to each, some weighing 5 ozs. Can they be used for food? Are they palatable? This year some stems have risen among the branches of a Fir tree to 9 feet in height, and are now in blossom all the way up. If of no use their ornament is great.—P. H. W.

[The tubers of *T. tuberosum* when cooked are eaten by the

natives of Peru. They have also been tried in this country, and been considered by some to form an agreeable dish. When boiled they are of a soft pulpy substance, and in flavour resemble Seakale mixed with the hot taste of garden Cress. Some who have thus used them state that they have a very delicate flavour like the richest Asparagus and superior to the Potato, but they are disposed to be watery and not to boil firm. It has been found that when used immediately after being taken up the tubers have a disagreeable taste; and to remedy this, in Bolivia, where the plant is called *Ysano*, they freeze them after they are cooked, and eat them when frozen. The ladies of La Paz are very fond of them, and in the season of the *taichas* large quantities are sopped in molasses and taken as refreshments during the heat of the day.—EDS.]

TOMATO AND CALCEOLARIA DISEASE.

I HAVE grown Tomatoes for seven years, and the first four years the plants had the disease seriously. The cause of the disease I consider was the result of turning the plants out too early, because during the last three years I have grown the same sorts in the same place and soil, and have had no disease but abundance of sound fruit. I used to plant them in May, but now do not plant until towards the end of June.

Now to the Calceolaria disease. I have a friend next door who always obtains cuttings from me. One sort only is grown. He inserts his cuttings in 48-size pots quite thickly. In the spring he pots them off; and when he does so, through their being so close together, their roots are greatly injured. When turned in the beds he loses nearly all with the "disease" as he says. I grow the same sort of cuttings from the same plants, but I insert them about 2 inches apart in a cold frame. In spring I take them up with soil adhering to their roots, and plant them about 8 or 9 inches apart in other cold frames; from there they go to the flower garden, and I do not lose above three or four plants all through the summer, and they bloom profusely. I grow about five hundred plants, my friend grows very many more.—W. L., *Barnet.*

DRESSING CARNATIONS.

It seems to me that in this controversy those who take the opposite side have the advantage over me. I always sign my name, they are anonymous, and under that cover are not over-particular what they say. "A STAFFORDSHIRE GROWER" in last week's issue wishes to "clear up a point or two." Now I am quite willing to make a statement on this point. If your correspondent will give his real name and address in this paper I will also publicly state whether I employ a professional dresser and how much I pay him for his services. There is one thing that is kept quite in the dark in this controversy which will open people's eyes to the one-sided way in which it has been carried on, and particularly by this correspondent. It is the fact that Mr. B. Simonite of Sheffield was competing against me in all the classes but three, I think. Now if it depends so much on the dressing of the flowers, how was it that in every case I beat Mr. Simonite? Will your correspondent answer that question? Again, if I did not exhibit honestly, how was it that Mr. Dodwell, Mr. Simonite, Mr. Rudd, and the other exhibitors, all of whom knew how my flowers were dressed, did not enter a protest at the time in the usual way? As to the letter signed "GILLYFLOWER," I did not know of it till I saw it in the Journal; had I done so I would not have allowed any reference to myself to have been published. As an exhibitor of many years' standing I have always been careful to comply with the rules of the schedules, and never to my knowledge did I infringe one. In the case of Carnations I adhere strictly to the rules of the National Society in their letter and spirit. If any real lover or intending exhibitor of Carnations had a desire for information on this subject the best way would be to write to the secretaries of the shows, and any complaint of dissatisfied exhibitors should be dealt with by the committee.

As to the time it takes to dress a flower, I can do four in ten minutes. I will relate an incident that happened at South Kensington as an illustration. At the last moment I was busy dressing flowers for the classes when I observed two lying in a small heap of flowers that I had cut in a hurry; and I remarked to Mr. Peter Veitch of Chelsea, who was looking on, that if I had time to dress them they would be placed first in their respective classes. I dressed them in his presence, and also placed the cards under them, I should say in less than

five minutes, as people were just being turned out. One was the scarlet bizarre True Briton that gained first prize; the other, I think, was the first-prize purple flake. Indeed while Mr. Veitch stood there I carded and dressed nearly a dozen. I fancy my friend "GILLYFLOWER" also saw me, hence his remarks. His remarks are also of the more value because he was placed second to me in one of the highest classes. As to the cutting from the paper, I presume we are now discussing the way of preparing these flowers for exhibition, and the words quoted were not used by me in that connection. I will not take any further notice of people who do not give their real name and address, or who have no other object in view than to wound the feelings of a successful exhibitor.—J. DOUGLAS.

PARISIAN NOTES ON PUBLIC PARKS AND GARDENS.

In copying out the following brief Parisian garden notes I shall proceed on the supposition that the readers of the *Journal of Horticulture* are lovers of Nature and Art, of sculpture and painting and their correlative fine arts, as well as of arboriculture and garden adornment. With this view it may not be injudicious to take *seriatim* some of the more prominent features, particularly noticing peculiarities, sights, and scenes individually, so as to avoid the confusion that would necessarily arise from attempting a reference collectively, sifting out what might be deemed unsuitable. The first thing that catches the visitor's eye are

The Market Gardens.—As you enter by the Western Railway (Gare St. Lazare) you are struck with the extent devoted to growing vegetables and fruit. Remembering there is a fixed population of two millions, and perhaps at present a large fraction of a floating one besides, this will not surprise. You will probably inquire what the long lines trained to low 3-feet trellis, resembling thin rows of Gooseberry bushes, are? These are open air Vines, and this is the usual way they are grown. On the other side of Paris, on either side of the line to Fontainebleau, I saw them more generally trained against walls. I may here say from the time you land at Dover, Dieppe, or Havre—I understand all over France—you see few cottages against the sides and over the roof of which a Vine is not trained. In several instances I tasted the fruit thus produced, and considered it sweeter than that grown indoors in England or Ireland, probably owing to the greater influence of sun and air. The prevailing kind appeared to be transparent green varieties, possibly varieties of Sweetwater or hardy Muscat with a French name. I rarely saw Black Hamburgh thus grown or sold in the shops. I need hardly say how cheap bunches of Grapes can be had in Paris. I saw no large canes as a rule—generally small and trained low. "What are the hundreds of bellglasses for?" inquired a Glasgow gentleman sitting near. These are also a peculiarity everywhere you turn. I believe, according to the season, they are variously utilised. Whole squares are covered thus, and in the sparkling sunshine at a distance the effect is undoubtedly remarkable. Lettuces at this season, and several other tender vegetables, are protected with them upon a very large scale. Although the expense of ground for garden purposes around Paris must be very considerable, I was surprised to find whole squares apparently unoccupied except by weeds, evidently since the Potato crop had been removed. This I noticed in several places; and while disposed to admit the excellence of the vegetables to be seen at the city vegetable markets near Notre Dame or in the Boulevard des Italiens, &c., I do not consider they can compare favourably with Covent Garden or even Dublin Market produce. Perhaps I may fifty take next

The Exhibition Grounds.—These are tastefully—splendidly—laid out. To avoid repetition, everything is neat and in the best taste within the whole municipal boundary from the point of view under consideration. Hosts of men are employed; why, although you have treey boulevards in all directions, no sooner has a leaf fallen, and they are doing so now as thick as those in historical Vallambrosa, than a sweeper with a long broom switches it and everything unseemly into a light vehicle kept constantly in motion. The result is that everything—streets and boulevards, crossings and pathways, bridges and quays, turf slopes and public lawns—are ever agreeable to look at. This applies still more to the grassy plots, large unprotected areas of which you see in all directions, including the lawns in the Exhibition grounds. Although 380,000 daily had on an average passed the turnstiles, on the week of my visit these lawns seemed so green and beautiful to look at that

it seems probable no foot ever touched them. These were one of the sights of this world's fair, and deserve more than a passing notice; but let me first say a few general words of this Exposition. It covers 150 acres in the heart of the city. When one has seen the London and Dublin parks, and public squares, and many private gardens, the floral display in those grounds or any part of the city will neither surprise or astonish. This may as well be at once said. The fountains at the main or Trocadéro entrance, with their circular and neatly kept carpet beds and daily-mown and hourly-watered turf, look healthy and beautiful. Worthy of notice, too, if only for contrast, were some borders near the Passy entrance, in which some fine specimens of subtropical plants attained large dimensions, while a wall behind appeared as if illumined, covered with *Cobæa scandens*, scarlet *Tropæolum*, and Virginian Creeper, the leaves of this latter having now assumed their well-known brilliant vermilion hue; indeed, all over Paris this appeared the favourite creeper for balconies and house fronts. The lawns and fountains, cascades and miniature lakes with strange devices, were special features. The exhibition of fruit and flowers drew much attention, but they have already been referred to in the Journal. The grass plots in which French and English houses competed with marked allotments for the best seed-sown lawn commanded considerable notice. The only, or two principal, English firms I noticed were Messrs. Carter of Holborn, and Messrs. Webb of Wordsley. Both looked fine and close, as did most of the French competitors. Since I returned a gentleman has informed me the Messrs. Carter received first prize, at which I was not surprised. The specimen greenhouses had many curious features, and were adapted to different circumstances, wants, and pecuniary abilities. Before parting from this ever-to-be-remembered world's fair I should notice the system of hydrants, with their attached light and convenient hose. You find them everywhere. They are used for grass, for walks, for roads, with a perforated nozzle, and must have had a most refreshing effect during the warm weather. Feeling the inadequacy of any observations within my limits I must still more hurriedly note

The Jardin des Plantes, combining the botanical features of Kew with the ornithological and zoological collections of Regent's Park, with many other additional attractions, as a free public library containing seventy thousand volumes, a chemical laboratory, and museums of natural history and anatomy. Here were placed Humboldt's American tropical collection of rare plants, and from a mound with a cast bronze pavilion splendid views can be obtained, not only of this extensive public garden, but of many interesting scenes around. The greenhouses, which are not proportionally extensive, I regret I cannot compare to Kew, and hardly to our own smaller but superb botanical garden at Glasnevin. The healthy appearance of the plants certainly loses much by contrast, if the drier atmosphere and climate does not partially explain it.

The Jardin d'Acclimation.—This should not be missed if possible by the visitor, if only to see the zoological collections, which were almost all eaten during the last siege, but since restored. Trees, lakes, walks, flowers, botanical collection, and sweet music, with many things to interest beside, can be here enjoyed; and for those satiated with noise, excitement, and the bustle of the city there is to be had the blest retirement and seclusion of quiet retired walks under drooping foliage, reminding one of the walk preferred by Addison in the Glasnevin Botanic Gardens, where, in company with his friend Tickel, they planned and wrote the immortal essays in the "Spectator" and "Tatler." Taking next some of the city public gardens I may appropriately commence with

The Tuileries Garden.—This, I understand, was originally an orchard, and has, I believe, undergone many fearful changes like the adjoining palace, from which the garden is separated by a new street. It has, however, at present a smiling appearance, and, like everything French, the characteristic is neatness and scrupulous cleanliness of walks, borders, and parterres. The constant use of the aforementioned syringing hydrants to flowers and grass maintains that healthy appearance on which visitors love to gaze. The blooming plants were principally very bright-coloured but rather dwarf Dahlias, *Chrysanthemums* (why cannot the gardening public of England and Ireland have early *Chrysanthemums* in August, September, and October, when there will be no danger of frost?) Tuberous Begonias, *Pelargoniums*, and smaller bedding stuff.

The Luxembourg Gardens.—These are hardly second to the last named in their extent, beauty of design, and the number of statues. The walks and flower beds are even handsomer, and

if nothing else were to be seen but its collection of five hundred Vines and Roses the visitor would be repaid. The fountains, basins, groups of statuary, and the magnificent style of architecture, not to mention the gorgeous contemporary paintings only second to the Louvre, would almost make one forget their botanical or floral interest.

Palais Royal.—The garden is rectangular, and in the centre military bands occasionally discourse sweet music. Around it is a well-kept leafy promenade, and on the side adjoining the Rue Rivoli (probably the finest street in Paris), along the covered-in verandah, are bazaars where one may reasonably buy almost anything. Cardinal Richelieu commenced this in 1639, and if he had a look at it now, except the fountain in the centre and the surrounding garden, he would have some difficulty in recognising it. Like so many of the finest public buildings in Paris, in 1871 the Communists burned the entire south wing. There are many other public and private gardens within the reach of the ordinary sightseer in the city, but we shall take next

The St. Cloud Gardens, the favoured residence of Napoleon III., and in which he received Queen Victoria in 1855. The statue terrace behind the palace, with the magnificent old trees and long expansive sweep of woodland, and the graceful flower parterres on each side, forms, it is said, one of the finest avenues in Europe. This may be said to be all that is left of this beautifully situated palace, for, except the blackened and charred walls, from which the screech of the owl alone is heard, all its glory is fled; enough remains on which to muse, perhaps "to point a moral or adorn a tale." One of the finest views of Paris can be had from the adjoining heights.

St. Germain.—This I lacked time to see, but was informed from one point of view, its chief attraction, besides its immense brick gloomy palace and surroundings, there is a terrace two miles long, which commands a splendid view of the valley of the Seine and its environs.

The Champ Elysées and Place de la Concorde.—Having still to copy a few notes in reference to the parks and cemeteries, and to conclude with Versailles, I can but briefly say that within the vicinity of both these—the first, the finest leafy promenade and the most brilliant, night or day, in Europe, and the latter the centre of the splendour of Paris—are some circular beds, generally having a fountain in the centre, artistically laid out in carpet fashion with peculiar devices, but I cannot say superior to Battersea or Victoria Parks in London or Phoenix Park, Dublin.

Bois de Boulogne.—This is the Hyde Park of Paris, the resort of aristocratic equipages and fashionable equestrians. The walks and drives are most tastefully kept, and turf, trees, and shrubs would form a desirable subject for a few hours' quiet walk or drive and musing study. Shaded alleys and retired walks can be found here as well as crowded thoroughfares; lakes, waterfowl, and even the marks of bullets on the bark of the trees. Strange, although the French climate is in advance of ours, the autumn appearance of the trees has not yet set in, except amongst the city Limes and Plane trees—the trees that appear to do best in the city of Paris as well as in the city of London.

The Buttes Chaumont.—The beautiful placid lake here, crossed by a gracefully constructed suspension bridge leading to a weird-looking craggy island cut out of the natural rock, is the special feature. It contains, it is said, nearly 60 acres, and cost about a quarter of a million to lay out. The rock is very steep, and is surmounted by the Sybil Temple with classic surroundings. The top is reached by winding and artistically constructed paths, with many very handsome flower plots. When you reach the summit you can survey on a bright day perhaps one of the most beautiful and animated panoramas in the world. Three-fourths of Paris and a hundred villages can be seen from this height—in fact, I was told the eye can take in a circumference of forty leagues.

The Parc Monceau.—This is the last of the many beautiful gardens and parks my limits will permit my noticing. The situation is very fine and convenient to reach, and it is to all appearance a most popular promenade and enjoyable retreat. During the last century of its existence it has undergone, like everything Parisian, many vicissitudes, passing from a banker to the Orleans, and then to the Napoleon dynasty, and ultimately in 1860 became public property. The garden is well deserving of special notice, as are the surrounding ruins, pyramids, cascades, rocks, and statues.

Cemetery of Père la Chaise, Montmartre, &c.—Although this beautiful "God's acre" has been the resting place, side by side,

of friend and foe innumerable (the guide told me it contained twenty thousand monuments alone), it is not old, having been given to the Superior of the Jesuits, Père or Father La Chaise, only in 1804. It contains 212 acres, rather highly situated, and commands an admirable view of the many surrounding scenes. The flowers and devices on the graves, the Yews, Cypress, and various evergreens, with the immortelles (among the rest one sent by Her Majesty on M. Thiers' grave), and many curious and unique contrivances to keep the memory of the departed green, go to prove that notwithstanding the gaiety of the people, there is still an abiding deeper feeling and perhaps a latent religious spirit. The plantations, walks, shady arbours, &c., are in the best taste. I come now to the last, but perhaps the most beautiful resort of all—

Versailles Palace and Gardens.—Like so many of the principal parks and gardens of Paris, this was laid out and designed by the celebrated Le Notre. After spending a day here we pause to collect our confused ideas and ask what has most astonished or surprised us. The enormous trees centuries old; the play of the fountains, admittedly the finest in the world, costing every time they play £400, and for which an American beside me said he would again cross the Atlantic to see alone; the statues, almost innumerable, any one of which would now-a-days make the fortune of a sculptor; the grottoes, cascades, lakes, vases, chaste flower beds, undulating and fantastic lawns and grassy slopes; but still more striking the quiet impressive grandeur and solemn sublimity that compel you to be silent while you admire. This applies even still more to the vast picture galleries of the palace. You gaze with mingled feelings of wonder and delight at the matchless paintings of David and De La Roche. But I shall not attempt what would be to me impossible, even a brief description *en passant*. Passing from those rich scenes I cannot do better than commend your readers to take the first opportunity of enjoying such treats, for a lifetime to be remembered.—W. J. M., *Clonmel*.

NOTES AND GLEANINGS.

MANY CHRYSANTHEMUM SHOWS are now pending. Amongst them we note Lambeth, and the North-Western (Camden Road) on the 11th; Putney, and Stoke Newington on the 12th; Brixton, and Dartmouth on the 13th; Walton on the 14th; Croydon, and Tunbridge Wells on the 15th; Borough of Hackney (Westminster Aquarium), Northampton, and Southampton on the 19th; Wimbledon, Ealing, Chelmsford, and Liverpool on the 20th; and Kingston-on-Thames on the 21st of the present month.

— WE are pleased to observe from a statement of accounts published by the SCOTTISH HORTICULTURAL ASSOCIATION that there is a balance in favour of the Society of £10 6s. 1d. The Association was instituted in March, 1877, its object being "the promotion and advancement of the science and practice of horticulture, and for the dissemination of a knowledge of such branches of natural history as are connected therewith." At the monthly meetings of the Society papers of great practical usefulness have been read, and the discussions that have risen thereupon have been highly instructive. Many new plants have been exhibited and adjudicated upon, and superior examples of cultivation have been recognised. Judging from the syllabus published for the session of 1878-9 much sound and valuable information is certain to be forthcoming on a variety of subjects, and we have no doubt that the Association, supported as it is by horticulturists and gardeners of admitted repute, will sustain its well-won reputation. The office bearers for the ensuing session are Mr. Malcolm Dunn, Dalkeith Gardens, President; Mr. Hugh Fraser, Leith Walk Nurseries, Vice-President; Mr. John Methven, 15, Princess Street, Edinburgh, Secretary; Mr. Alexander Milne, Leith Walk Nurseries, Assistant Secretary; and Mr. D. P. Laird, West Coates Nursery, Treasurer. Committees of special competency are appointed to adjudicate upon new plants, fruit, and vegetables, and the entire Association is in admirable working order.

— WRITING on the WHITE JAPAN ANEMONE Mr. Brotherston observes: "This is an extremely useful hardy plant, of purest white in the flower, and rivaling *Eucharis amazonica* as a cut flower. The finest flowers are produced on young plants, and these have the further merit of blooming later than old plants. The foliage is also useful for large vase-furnishing. It is of easy propagation by division, and extends so rapidly at root that I should imagine where left to itself for a few years it would be found to appropriate more than its own share of the border. October is the best time to take off

the root offsets, as dry weather is apt to set in before they are established when divided in spring."

— MR. C. T. WALLIS informs us that the following **SHRUBS AND PLANTS** were flowering during the last week in October in his garden in Surrey, which is fully exposed to the north:—*Arbutus*, *Antirrhinums*, *Berberies*, *Bluebells*, *Calceolarias*, *Chrysanthemums*, double *Daisies*, *Escallonia macrantha*, *Fuchsias*, *Hawthorn*, *Hollyhocks*, *Laurustinus*, *Leycesteria formosa*, *Mahonias*, *Michaelmas Daisies*, *Mignonette*, *Myosotis*, *Primulas*, *Pyrethrums*, *Pansies*; *Boursault*, *China*, *Hybrid Perpetual*, *Noisette*, and *Tea-scented Roses*; *Strawberries*, *Sedums*, *Sweet Williams*, *Tritonias*, *Tradescantias*, *Tropæolums*, and *Violets*.

— "We visited," says "S. H.," "a few of the **CHRYSANTHEMUM GROWERS** about Liverpool a day or two ago, and saw both plants and blooms very fine, particularly Mr. Bateson's and Mr. McIver's, both in Allerton Road. We noticed in Mr. Bateson's conservatory splendid blooms of the variety *Aurea multiflora*, and in Mr. McIver's grand blooms of *Eve*."

— AN American correspondent writing to us from Wisconsin states that the SEASON there has been one of the most unpropitious on record. His garden, he states, has been rendered quite profitless by the excessive rains. After the storms the sun was so powerful that it made the water so hot everything looked as if scalded. Potatoes, Carrots, Cabbages, Turnips, Tomatoes, Onions, and Currants—all were destroyed.

— "J. J." writes to us as follows on the **SULPHUR RECIPE FOR KEEPING FRUIT**. "I think anyone trying the receipt should do so on a small scale until they prove it. I have tried the plan recommended and find it has injured many Apples and Pears. Some have become quite soft all round to the depth of, say, a quarter of an inch, and others have become blotched and spotted, which entirely spoiled their appearance; and yet others done at the same time do not seem to be affected at all. I shall be glad to hear the result of other experiments. The recipe is not explicit enough—'two tablespoonfuls of sulphur in a box.' A box is a box, but one might be 2 feet square and another 2 yards square. The correct way would be to say how much sulphur is required to a cubic foot of space, and then we could give the plan a fair trial. I hope 'A KITCHEN GARDENER' will let us know how he succeeds."

— "H. E. A." communicates the following note on **SEEDLING BRIARS**:—"I can fully endorse the statement of the Rev. W. F. Radclyffe on page 332, that the seedling Briar rivals all other stocks used for working the Rose on. We have about five and a half dozen, which we received at different times direct from Mr. Prince of Oxford, for filling-up gaps in our Rose borders, and I can point them out to any person almost as far as I can see them from their dark green foliage, strong firm regular growth, and fine flowers. They throw few suckers."

APPLEY TOWERS.

APPLEY TOWERS, the seat of the Right Hon. Sir William Hutt, K.C.B., is situated a short distance from the neat and picturesque town of Ryde, Isle of Wight, and the road is itself also very beautiful, passing as it does most of the villa residences of the noblemen and gentlemen who stay there during the yachting season, and who keep their gardens gay with choice flowering shrubs and the usual summer bedding plants.

On entering Appley from the entrance lodge, which is a very handsome structure of the same style of architecture as the mansion, the house is speedily reached. It is a highly imposing building in the Tudor-Gothic style of architecture. The mansion, with the gardens and estate, have been all remodelled by Sir William since he purchased the demesne some six or seven years ago. The whole resources of architectural art and modern science appear to have been brought into requisition in finishing the building, which for completeness—ornament combined with utility—is altogether unique. At the east end of the mansion has been built a very handsome clock tower, something after the style of that of the Houses of Parliament at Westminster, the materials employed resembling those of the grand classical towers at Nice and Genoa. This rich and lofty tower greatly enhances the beauty of the entire building. There has also been added to the estate a model farm, complete in every detail, with a turreted water tower, which supplies the wants of the gardens and the estate generally. Gas also is made on the premises for supplying the estate, whilst the stables and other adjuncts are complete in every modern detail. From the mansion electric bells are employed for communication with the heads of each department, so that

the owner can have immediate communication with such when required; in fact, every department appears to lack nothing that art can produce.

Appley Towers is charmingly situated. Nature alone seems to have been profuse in her beauty there. The mansion being on an eminence commands extensive views of the sea stretching as far as Falmouth and along the adjacent coast, and the grounds have been so arranged as to show "Nature's pictures" to the best advantage. A sea wall is built for the protection of the property, and the whole pleasure grounds, extending over many acres, are laid out with judgment and taste.

Great skill has been exercised in their planting; but that, perhaps, which renders Appley the most interesting is the work of acclimatisation that is carried out on a scale unequalled perhaps in any other establishment in Britain. To this important work the proprietor devotes especial and personal attention, and in carrying it out he is ably supported by his painstaking gardener Mr. Sunbury. The results obtained cannot but be beneficial to horticultural science in general, for there is perhaps no department of gardening so little understood as that of acclimatisation. Amongst gardeners generally the predominating object seems to be that of coddling, but no protection is ever given to any plants at Appley during the winter. The list of plants we enumerate are such as have been proved perfectly hardy after two or three years of trial of them, while the good work is still progressing. Many hundreds of stove, New Holland, and Cape plants have been planted out this year, and have thrived so far very satisfactorily.

On entering the grounds from the orangery—which is in a line with the mansion and is 50 feet by 20, and well stocked with fine Orange trees, the roof finely covered with the red and white *Lapagerias* beautifully interlaced—the eye is entranced by a huge belt of *Hydrangeas* 5 or 6 feet high skirting a shrubbery, in full bloom on October 11th. This is easily seen from the principal drawing-room, from where the present view is taken; also beds of *Fuchsias* of the choice greenhouse varieties were very fine. *Eucalyptus globulus* is planted extensively, all of them having been raised from seed received from Nice and Algiers. Although only planted two or three years the trees have attained the height of from 20 to 30 feet. There is also the Peach-leaf-shaped *Eucalyptus*, which attains the height of 420 feet in its native habitat—Australia. *Araucaria brasiliense* quite luxuriates at Appley. Messrs. Veitch & Son sent Sir William a dozen seedlings in a pot for trial, and it is gratifying to record how well they have succeeded. Some of them are now 3 and 4 feet high. *Erythrina Crista-galli* had also been splendid, and the *Nerium Oleander* was grand, flowering profusely. *Abutilon* *Boule de Neige* flowers well as a hardy shrub, also *A. vexillarium*. *Habrothamnus elegans* had flowered twice; *Eriostemon*s, *Desfontainea spinosa*, *Correa Harrisii*, *Grevillea rosmarinifolia*, *Acacias longiflora*, *armata*, and *coccinea*, *Boronia serrulata*, *Genetyllis fuchsoides*, *Rhynchospermum jasminoides*, *Dasylium*s, *Aralia papyrifera*, *Dracena indivisa*, *Phormium tenax*, *Dicksonia antarctica*, *Alpholphia excelsa*, and the Breadfruit Tree (*Artocarpus incisa*), have all stood the test of full exposure.

Cassia corymbosa in beds 20 and 30 feet long, one mass of rich golden yellow, was a sight not easily to be forgotten. *Bouvardias* do well and flower most beautifully, as also do *Clianthus puniceus* and *magnifica*; to which we must also add another choice greenhouse climber, *Cantua dependens*. How seldom is it we see this lovely climber in our greenhouses, and yet what can be finer than its fine and charming rose-coloured racemes of flowers in the spring? Amongst choice flowering shrubs Indian *Azaleas* and several of the mollis section are planted out, and there is a fine collection of choice *Rhododendrons*, and many rare and beautiful *Aucubas*; amongst them *Youngii medio-picta* was very attractive.

The ends of the conservatory, a building 63 feet by 23, is finely covered with climbing plants. This house was undergoing cleaning and repairs during our visit; it is seen from the house, but it is the white and red *Lapagerias* planted outside that demand attention. They are both magnificent plants and produce their flowers in large clusters. These plants cover a large superficial area, and seem to delight in having full scope to display their floral wreaths. Outside in a narrow border were flowering profusely *Guernsey* and *Belladonna Lilies* and *Nerine Fothergillii*. At a short distance from the conservatory is a very beautiful aviary containing many rare species of parrots, &c. Many flowering plants and trees cannot be noticed, but we must not omit some of the following—*Myoporum parvifolium*, *Lomatias*, *Edwardsias*, *Banksias*, *Mag-*

nolias in variety, and all the greenhouse varieties of Veronicas quite 5 and 6 feet high. Myrtles are numerous and do well, the saline air seeming to agree with them admirably. *Iochroma grandiflora*, *Hovea Celsii*, *Metrosideros floribunda*, *Philesia buxifolia*, and the Guava (*Psidium Cattleianum*), probably the only acclimatised specimen in Britain, and *Poinciana Gilliesii* are all thriving well in the open air.

There are some huge beds of Camellias quite covered with buds and having remarkably fine dark green foliage. Sub-tropical bedding is done largely and embraces all the usual plants for such purposes. There are also some fine beds of Clematises, the figures being segments of circles, effectively planted; and contrasting effectively are such Conifers as *Araucaria excelsa*, *Cedrus Deodara*, *Wellingtonia gigantea*, from 30 to 45 feet high. For affording brightness and relief to the shrubs an ingenious expedient is resorted to. About five stakes 6 or 7 feet high are driven into the ground; these are encircled with wire netting, filled up with soil, and planted

with *Vesuvius Geranium* trained round the wire netting. These cones of scarlet flowers contrasting so well with the surroundings need to be seen to be appreciated. There are two flower gardens, one in front of each side of the mansion, which contain thousands of bedding plants, but on these I need not dwell.

The kitchen gardens and forcing houses are on the opposite side of the road. The glass is extensive. The first range is 120 feet long, divided into four divisions of 30 feet each; the first being devoted to Cape plants and a few cool Orchids, the second and third to Cucumbers and Melons, and the fourth is a propagating pit. The next range is of the same dimensions, and contains four vineries; the first being the early one, planted with Black Hamburg, Frankenthal, and Foster's Seedling; the second a Muscat house, which contained some very fine bunches, plump in berry and fine in colour; the third is a second Hamburg house; and the fourth contains Lady Downe's, Alicante, Gros Colman, Bowood Muscat, &c. Some

Fig. 55.—APPLEY TOWERS.

of the Bowood Muscats were especially good and spotless in colour; the wood was matured well, and the crop ample.

The next range is a set of span-roofed houses 120 feet long by 20 wide; the first being a plant stove 45 feet long, and contains the curious crab-footed plant, *Testudinaria elephantipes* (the female variety), also *Hedychium coronarium* with its white perfumed flowers, *Rondeletia speciosa*, Crotons, and the charming *Tabernaemontana coronaria flore-pleno*. Is it not a wonder we see this lovely plant in so few collections? The same may be asked respecting *Combretum purpureum* with its fine racemes of purple flowers, a colour rare in stove plants. *Gardenia Stanleyana* had flowers 7 inches long. *Vanda teres*, &c., all in excellent health and had made very good growths. The next division is a fruiting Pine stove, which contained good fruit of Queens and Smooth-leaved Cayennes on plants just sixteen months old. The last division is an intermediate Orchid house. These last three divisions are 25 feet long, and all are devoted to Orchids.

Six ranges of pits each 48 feet long are provided for growing and forcing vegetables, Strawberries, successional Pines, &c., and are admirably adapted for the purpose. About 1200

Strawberries were plunged in ashes. Vicomtesse Hericart de Thury, Keens' Seedling, and Sir Joseph Paxton are the sorts chiefly forced. A range of glass is on the top of the kitchen garden, 200 feet long, and divided into three compartments, is devoted to Peaches, one of the divisions being used as a cool orchard house for Apricots, &c.

The next portion of the kitchen garden, which is divided by a wall, contains a house 40 feet by 25, full of specimen Azaleas, Cape Heaths, Australian plants, with a *Maréchal Niel* Rose trained on the roof. Most of the glass has been recently erected. Wright's boiler has been lately adapted for heating purposes, and Mr. Sunbury speaks very favourably of it.

The kitchen gardens are well cropped, and their good keeping is in unison with the rest of the establishment. Fruit has not been very plentiful this year, nor does it ever seem in great abundance at Appley. Apricots scarcely ever produce a crop, perhaps this may be accounted for by the comparative absence of sun when most required in the autumn; neither are vegetables so early as might naturally be expected.

In concluding our notes on these gardens it is pleasant to record the confidence that exists between employer and employed, which is always advantageous to the well-being of every establishment. I had a rich treat at Appley, and I shall not soon forget the kindness of Sir William Hutt in

pointing out objects of interest and giving information where it was required.

Appley Towers, its grounds and gardens, afford remarkable evidence of good taste on the part of the proprietor, and the gardener, Mr. Sunbury, is to be congratulated on the excellence of his work in the several departments under his charge.—B. COWAN.

LASIANDBA MACRANTHA FLORIBUNDA.

I KNOW of few plants so gay with its large purple flowers and fine foliage as this. *Lasiandra macrantha* is well known, but is unfortunately straggling in growth and sparse in flowering; but the plant figured is dwarf in habit and floriferous. Under easy culture this valuable plant may be had in flower

from the end of October till the end of February. It is very useful in small 32-sized pots for various purposes of decoration. I have found it strike freely in the early spring—about the end of February—plunging the pots containing the cuttings in a house or frame having a temperature of about 60° to 70°; the cuttings also strike if placed loosely in cocoa-nut fibre. After they have rooted, which will be about the end of March, they should be potted singly and again plunged in heat until established. We shift them into their blooming pots and keep the plants in about the same temperature until May; they may then be removed to a pit or frame and kept rather close. They also enjoy a little shade in hot weather. About the first week in September remove the plants to where they are to flower if continued in the frame much later than that time they will lose some of their flower buds which are then formed; the

Fig. 56.—*LASIANDBA MACRANTHA FLORIBUNDA*.

foliage also will turn brown at the edges and spoil the appearance of the plants.

I find the plants flower well in a temperature of from 50° to 55°. If the house is kept rather dry it will suit them all the better. The soil I use for potting this *Lasiandra* is bright yellow fibry loam and peat in about equal parts, using plenty of silver sand. It is a plant that also requires a liberal supply of water.

Lasiandra macrantha floribunda was, I believe, first sent out by Mr. Bull, but it is now in general but too limited cultivation. Recently a fine batch of plants was flowering in Messrs. Veitch's Nursery at Chelsea, none of them exceeding 18 inches high, and every shoot producing four or five grand flowers.—J. PITHERS.

CHRYSANTHEMUMS IN LONDON.

AFTER a long period of well-applied labour and unremitting attention Mr. Newton has his reward in the attractive display

of *Chrysanthemums* in the Inner Temple Gardens. As usual the plants are arranged on the south border of the gardens, which is temporarily covered with glass, the front being protected with canvas. The border has been excavated so that the flowers are placed conveniently under the eye, and, sloping from the back to the front, the bank is highly imposing. It is about 50 yards long, 6 feet wide, and contains nearly five hundred plants. They are grown on single stems, and bear on an average about six blooms each. Mr. Newton grows all the best old varieties in cultivation, adding each year new varieties as they are produced. As a rule the new are no improvement on the old; such familiar sorts as Mrs. G. Rundle, The Beverleys, Prince Alfred, Jardin des Plantes, Vesta, Dr. Sharp, White Globe, King of Denmark, Progne, and the small but useful *Julie Lagravère*, are as attractive as ever, while of the Japanese varieties *Elaine* is still unsurpassed for pure chaste beauty. Amongst the newer *Chrysanthemums* one of the richest of all, *Refulgence*, will never become popular on account of its glaring yellow eye. M. Lucien Barthière, a

small, close, imbricated flower, is very rich—just the colour of the crimson velvet of good French Marigolds, with bright yellow tips. It is useful for decoration but not for exhibition. The same may be said of Comte de Ranzau, very dark, and Mount Etna. Gloire de Toulouse (Japanese), is a fine dark purplish rose flower; Cri Kung, pure rose, is also good; and La Nymph, a small satiny rose, is very chaste.

By the kindness of the benchers of the Honourable Society of the Inner Temple the gardens are open to all, and Mr. Newton is to be congratulated on the excellence of the display.

BOTTLING FRESH FRUIT.

IF "A PUZZLED HOUSEWIFE" will try the following plan for fruit such as Gooseberries, Cherries, Raspberries, Currants, Damsons, &c., she will not fail to succeed, as I have used it for some years, and the fruit keeps well and is as good as when gathered.

Fill clean wide-mouthed bottles with the fruit. Pour nearly boiling water into the bottles slowly up to the neck, or as much as will cover the fruit. The water must have alum dissolved in it to the proportion of one drachm to four gallons, or fifteen grains per gallon. Let them become cold: fill the bottles up with some more of the alum water warm; then bung them up, place them up to their necks in a copper of water or iron pot, with hay to keep them in position, and bring them up to the heat of 176°; then take them out and bladder them, and seal the bladder if greater security is wished.—E. S. S., *Dudbridge*.

THE WARS OF THE ROSES.

I AM glad to see that the little wars of the Roses have come, apparently, to a termination. "WYLD SAVAGE" undertook a rather invidious task in attempting to assign relative positions to the leading amateurs, and it would be much better if any remarks which might become a *casus belli* amongst rosarians were avoided. I look upon the extreme—I may almost say the utter *abandon* of good fellowship that exists among the devotees of the Rose, as by no means the least of the many pleasures incidental to Rose-growing and Rose-showing; and I venture to express a hope through your columns that the little volcano which has lately sprung up in our ranks has now become, not dormant but, extinct.—A. G. S., *Ingham*.

DRESSING FLOWERS.

MR. DOUGLAS'S statement about dressing a stand of Hyacinths having been more than once referred to as if it were a fact, allow me to say that it is utterly incorrect. I saw the stand before he touched it. I saw him doing it, which consisted simply in lifting up the bells. I saw the flowers staged on the occasion, and I have no hesitation in saying that had he never touched them they must have won, as being by far the best shown; and I very much question whether the formality introduced into them by the dressing did not rather spoil than benefit them, but at any rate it had nothing to do to their obtaining a prize.—C.

NOTES ON VILLA AND SUBURBAN GARDENING.

LAWNS, walks, and pleasure grounds now require more than ordinary attention. Leaves are fast falling, and must be cleared away. If possible, choose dry weather for sweeping, for both lawns and walks will present a cleaner and better appearance than when swept during wet weather. Leaves are very useful for mixing with long stable manure for making hotbeds, or the forcing of Seakale and Rhubarb. Oak and Beech leaves are decidedly the best, giving more heat and lasting longer than those of the Horse Chestnut, Elm, or Lime, although these will be found useful, and must not be rejected. After the leaves have been collected, both lawns and walks will be greatly improved by a thorough rolling. The borders should be edged and the beds dug over, carefully burying the leaves, or they will prove troublesome and be wafted about by every wind that blows. Much of the beauty that is attached to pleasure grounds during the summer months is wanting now. Order and neatness must take its place; and it is only by turning the beds, having neat edges and well-kept walks, that this can be done. A few flowers yet linger in the herbaceous or mixed borders. The various-tinted Asters or Michaelmas Daisies, the white and pink varieties of the Irish Heath (*Menziesia polifolia*), the tiny but bright blue-flowered

Lithospermum prostratum, the Daisy-like *Vittadenia triloba*, and *Chrysanthemums* are all attractive; while amongst the evergreen shrubs the *Arbutus* tree is now conspicuous with its hanging clusters of pure white and ruby-tinted flowers contrasting with bunches of ripe golden fruit. We never remember seeing the *Arbutus* so profusely bloomed and berried as it is at the present time. In most places the grass has grown freely during the mild weather, therefore it may be found necessary to use the mowing machine on a dry day, after which the machine should have a thorough cleaning and be laid up for the winter; or if through constant use it has become out of repair, the present is a good opportunity of sending it to the makers to be re-adjusted.

Besides the above-mentioned smaller items connected with the outdoor duties of a garden, the present time is suitable for the more important work of removing, transplanting, and renovating clumps and borders of mixed hardy shrubs. Often in forming new villa gardens shrubs are at first planted too thickly, with the view of immediate effect; consequently, after they have made a few years' growth the shrubs spoil each other. In such cases it is best to lift all that are not too large for removal, and to transplant them in some more important position. In the case of very large shrubs we have found it advisable to cut around the roots during the summer, that they may now be the more successfully transplanted in suitable quarters. In transplanting shrubs of all kinds experience has taught that they make the most rapid progress in ground that has been well trenched and kept clean, and free from weeds afterwards, until the shrubs are well established. A very frequent mistake often made in small places is that of planting choice *Coniferae* close to buildings or very near the edges of walks, and after a few years it becomes necessary either to divert the paths or subject the specimens to the very barbarous system of lopping the lowermost branches. The character of the plant should be known before planting, hence the necessity of employing experienced persons. In planting single specimens, always make the holes considerably larger than the space required to receive the roots, well breaking up the bottom and sides with a long-pronged fork. In poor gravelly soil we have often been obliged to remove the gravel and replace it with better soil, but it is remarkable how most shrubs will thrive, even in a poor gravelly soil, if it is thoroughly broken up beforehand. Masses or clumps of mixed shrubs are highly attractive the whole year round, especially when there is plenty of flowering plants introduced, such as *Lilacs*, *Deutzias*, *Philadelphuses* (Mock Orange), *Spiraeas*, *Ribes*, *Laburnums*, *Rhododendrons*, *Kalmias*, *Azaleas*, *Cratægues*, *Berberis*, &c., interspersed with them. *Portugal Laurels*, the common *Laurel*, *Yews*, variegated and other *Hollies*, *Box*, &c., are suitable for the background, and the dwarfier and closer-growing plants in front. Many of the *Euconymuses* are attractive from their glossy green or variegated leaves; especially well do these thrive by the seaside. *Negundo fraxinifolium variegatum* may be freely introduced with good effect; while some of the *Magnolias*, especially *conspicua*, are highly attractive while in bloom. Among the smaller-growing *Coniferae* are some dainty plants of *Retinospora plumosa* and *R. plumosa aurea*, *R. filicoides*, *R. obtusa aurea*, *Thuja aurea* and *elegantissima*, *Thuja borealis variegata*, *Cupressus Lawsoniana erecta* and *gracilis*, *Abies polita*, and many others. *Wellingtonias*, *Cedrus Deodara*, *Piceas Nordmanniana*, *Pinsapo*, and *nobilis* may be planted singly where there is plenty of room for them to develop their rapid growths. Stake every specimen securely that is likely to be blown about by the rough winds which may prevail as soon as the newly-shifted plants begin to emit fresh rootlets, when much injury is done. The above remarks apply with equal force to newly-planted fruit trees; but care must be taken in staking these and all deciduous trees that the stake is not put so close to the stem as to chafe the bark, which should be protected with a piece of leather or other soft material.

Briars for next year's budding should be planted at once. Many of the rough gnarly old roots require cutting off clean and smooth. Plant them about a foot apart in rows and 2 feet 6 inches between the rows, where they should remain to be budded next summer. Orders should also be given at once for Rose trees required from the nurseries, for there is often a great run on many of the varieties, and when orders are given late the best plants have all been chosen and sent away. Plant those worked on the Briar a similar depth to what they have been already growing in, but dwarfs worked on the *Manetti* should be planted below the union. A selection of the best varieties may be easily obtained by referring back to the election so recently given by the kindness of Mr. Hinton; as a general rule the Roses that take the foremost rank there are the best garden Roses. Order quickly, plant quickly, and plant in rich, deeply dug, and well-manured soil.

Where *Chrysanthemums* are grown well conservatories will be very gay; in fact, we have recently seen several structures, and we consider them gayer now than at any time during the whole year. Damp is the greatest enemy now to the *Chrysanthemum*, and must be guarded against. In unheated houses the moisture condenses on the roof and afterwards drops on the flowers, therefore air must be given as early as possible to dry the house and preserve the flowers. Many of the Japanese varieties are

extremely curious and beautiful, and some of them, being late openers, are additionally useful.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Sowing Peas.—A first sowing may now be made upon a south border. William I. is the best of the early Peas, First and Best being excellent, Sangster's No. 1 (Daniel O'Rourke) though somewhat later is an admirable cropper, and Ringleader (syn. First Crop) is valuable for its earliness. Harbinger is, however, the earliest of all, and where very early Peas are in request it may be sown about 3 feet 6 inches from a south wall and parallel with it; or it with those approved may be sown cross-wise of the border in rows 3 feet apart. We, however, sow in rows 4 feet apart, having Lettuces planted between the rows as stated in a former calendar. For sowing in front of south walls, 12 to 15 inches from the wall, Unique, Blue Peter, Premier Gem, Beck's Gem (Tom Thumb), and Little Gem are all good. In sowing Peas it is necessary to take precautionary measures against mice. We moisten the Peas with water to which a table-spoonful of paraffin has been added to a gallon and thoroughly mixed. Whilst the Peas are wet we coat them with red lead thoroughly before sowing, and though we are overrun with rats and mice owing to the proximity of game covers, we find the Peas are safe from those vermin and pheasants. The Peas are just covered with soil, and then with sifted ashes about an inch or so deep, which assists in warding off the ravages of slugs. A first sowing of Broad Beans may be made upon a warm border. Beck's Gem is a good, dwarf, early sort; Early Mazagan is only desirable for its hardness, Early Longpod being preferable to it; Seville Longpod is earlier than other forms of Longpod, but none are so hardy as the Mazagan. We treat the seed the same as the Peas, covering about double the depth. We would urge the desirability of removing the yellow and decayed leaves from all the crops of Brassicas that are intended to stand the winter, so as to admit air to the stems and harden the growth before severe weather sets in. Draw a little earth to the stems of early Cabbages so as to keep them steady against winds.

The pricking-out of Cauliflowers under the protection of a wall must not longer be delayed; the small plants remaining of the August sowing after planting in frames or handlights will, if the winter be not unusually severe, be found useful for transplanting in spring. Lettuces may also yet be planted at the foot of walls.

Forcing Department.—If new Potatoes are required very early, and there is convenience for growing them in light situations near the glass in heated houses or pits, sets may now be inserted singly 3 or 4 inches deep in efficiently drained pots filled to within an inch of the rim with two-thirds of turfy loam and one-third of leaf soil or thoroughly decayed hotbed manure. Early lifted tubers should be selected for this purpose and those that have commenced sprouting. Veitch's Ashleaf and Myatt's are the best. They may be placed in any house where there is warmth until the growths appear above the soil, when they must have light; a vinery or Peach house at work having suitable temperature, or any light airy house or pit with a temperature by artificial means of 50° to 60°, will answer. A 9 or 10-inch pot will be suitable for one set, but three sets may be inserted in 11 or 12-inch pots. Peas of the dwarf kind are sometimes forced, but unless there is plenty of accommodation, as that afforded by Peach or orchard houses, they do not afford satisfactory returns. They may be sown now in 10-inch pots filled with good loam, a double row inserted an inch from the side and covered an inch deep. They cannot have too much light and air, 50° being quite high enough for them in dull weather. French Beans should be sown for succession, keeping those more advanced as close to the glass as possible, feeding those in bearing with weak liquid manure. Maintain the supply of Mustard and Cress by frequent sowings.

FLOWER GARDEN.

Frosts have blackened the Dahlias in some parts. Where this is the case cut off the stems about 9 inches from the ground, and the roots may be lifted and placed upside down in a shed for a few days for superfluous moisture to drain off, and then be plunged in moist sand in a cool place, where they will be safe from frost. If the weather be mild they may be left in the ground as long as possible, especially those from cuttings in spring, it being a great mistake to keep the tubers so dry as to induce shrivelling. Marvel of Peru roots also should be taken up and treated in a similar manner; Cannas, Tritonias, Tigridias, and other tender roots may be left in the ground if the bottom be dry, and be covered with sifted coal ashes in the form of a cone to ward off wet and frost, but if the site is at all wet the Cannas should be lifted and stored away in sand safe from frost. Tuberous-rooted Begonias often winter safely in the ground if it is well drained and a covering of ashes is given, which is better than cocoa refuse and leaf soil, which worms delight in; and birds in turn, having a great liking for the worms, clear away the material from the crowns, but ashes they do not interfere with. If the soil be wet take up the tubers and store them away in moist sand in a place safe from frost. A

covering of ashes over the bulbs of choice Lilliums is desirable, formed cone-like to throw off the wet and to afford protection against frost. The planting of bulbs may still be proceeded with, but the sooner it is completed the better.

FRUIT HOUSES.

Vines.—These for affording fruit in April must now be started, whether they be in pots or planted out. Bottom heat in neither case is indispensable, though in all forcing operations it hastens growth considerably; therefore, plunge the pots in a bed of fermenting materials as before advised, suspending the rods in a horizontal position over the fermenting materials to insure a regular break. Syringe three times a day, keeping every part of the house moist by sprinklings in bright weather. Vines started at this season require a higher temperature to excite the buds than those started later. A temperature of 55° to 50° at night and 60° to 65° by day will not be too much to start with. Those planted out should have the inside border thoroughly soaked with water at a temperature of 90°. The border or floor of the house should if convenient be covered 2 feet deep with leaves and stable litter in a state of fermentation, occasionally turning over the material, as the moist ammonia-charged heat given out is very beneficial to the Vines. The outside border must be attended to as to warmth and covering from heavy rains. The Vines in houses for starting in December should be pruned at once, as it contributes to early and complete rest. In pruning two eyes are ample for affording useful bunches, but if large bunches are wanted longer pruning may be practised; yet what is gained in size of bunch is lost in size of berry, compactness of bunch, and good finish. Remove dead and decaying foliage from the Vines where ripe Grapes are hanging, and look over the bunches frequently for decayed berries. Any Vines not yet hard and brown in the wood should be kept closely stopped, fire heat being still applied accompanied with free ventilation.

Cucumbers.—Maintain a night temperature of 70°, a few degrees less in severe weather, advancing to 80° and 85° with sun heat. Admit a little air at the top of the house whenever the weather is favourable, but it must be done without lowering the temperature, it being better to shut-off the top heat for an hour or two when the sun is powerful than to admit air when the winds are very cold. Moderate ventilation is, however, beneficial in carrying off steam, &c. The syringe may be laid aside except for damping the paths, walls, &c., in the morning and afternoon in warm bright weather, keeping the evaporation troughs filled with liquid manure. The water given to the roots must be of the same temperature as the house, as also must the soil that is added to the beds. The autumn fruiters being now in full bearing must not be overcropped, therefore remove the fruit when it attains a fair size, also all deformed fruit. Go over the plants at least once a week for the removal of bad leaves, and for stopping and cutting away superfluous growths. Let the winter fruiters advance well up the trellis before stopping them, training the side growths afterwards at right and left angles from the main stem. Allow few or no male blossoms nor tendrils, removing them as fast as they appear, and add fresh-warmed soil as often as the roots have fairly covered the surface of the bed.

Pines.—Liberal ventilation should be afforded to houses or pits containing young plants whenever the weather is favourable, and avoid damping, as keeping the houses constantly saturated is more injurious than otherwise. Water will not now be required frequently, yet the plants must be examined every ten days, watering such as require it, as too great dryness is more prejudicial than is commonly supposed. In the fruiting department lose no opportunity of closing the house at 85°, keeping the night temperature at 70°, or a few degrees less in cold weather. Remove all the superfluous suckers, retaining one only, the best on each plant. Suckers on successional plants that appear before the fruit is visible should be removed, except an increase of stock is urgent. At this time of year it is usual to make new or replenish the beds of fermenting material for the young plants. Tan is unquestionably the best material; a good substitute being found in Oak or Beech leaves, which should now be collected as dry as possible. In forming beds of leaves they should be firmly pressed; tan, on the other hand, should be placed lightly together.

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense. Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

BOOKS (W. E. K.).—The "Greenhouse Manual," published at this office (post free 10s.), contains instructions on the cultivation of greenhouse flowers. (J. T. A.).—We cannot recommend a more useful moderately priced

hook for the purpose you require than the "Cottage Gardener's Dictionary." The cultivation of all the crops you name and many others is given fully and practically, as also are the propagation and culture of all useful fruits and popular flowers. The book can be had from this office, price 6s. 6d., or 7s. 2d. post free.

PLANT COLLECTING (J. C.).—A thorough knowledge of plants is necessary by a collector. We can only advise you to state your requirements and qualifications to some of the leading nurserymen.

VINES INFESTED WITH MILDW (North Wales Fruit-Grower).—There is no question of the efficiency of flowers of sulphur applied upon the first appearance of the parasite. The Grapes cracked and spotted when they began to colour because the atmosphere was too moist and close. Freer ventilation with brisk firing, and the coating of the hot-water pipes with flowers of sulphur brought to the consistency of cream with skim milk, would have produced an atmosphere unfavourable to the fungus. As the leaves fall burn them, and when all are fallen prune the Vines, strip off the loose bark, consigning it and the pruning to the flames; thoroughly clean the wood-work of the house with soap and water, the glass with water only. Wash the Vines with a solution of soft soap (8 ozs. to the gallon), removing the top 2 or 3 inches of the border, and limewash any wall surface. If necessary paint the wood and trelliswork, and then dress the Vines with a composition of 1 lb. of soft soap to half a gallon each of water and tobacco juice, adding equal proportions of fresh-slaked lime, flowers of sulphur, and soot to bring it to the consistency of cream, applying with a brush to every part of the rods. If the border be efficiently drained and the roots near the surface replace the removed surface soil with fresh turfy loam, adding about a twelfth part of charcoal moderately small, and a twentieth each of half-inch bones and wood ashes; but if the drainage be defective rectify it, and if the roots are deep raise them carefully to within about 6 inches from the surface in the fresh material. Mulch the border with about 6 inches of fresh litter, and if convenient cover it with hot dung and leaves three weeks before commencing to start the Vines into growth. We think the principal cause of the mildew is too close and moist an atmosphere, induced by a deficiency of ventilation.

LIQUID MANURE FOR GREENHOUSE PLANTS (D. W.).—The time to fill a cask with liquid manure is when you require to apply it, but it must not be applied without discrimination. As a rule softwooded plants advancing for flowering, the roots being confined to small pots, only require rich stimulants. Guano at the rate of 1 oz. to the gallon of water is sufficient, and may be made as required. The drainings of the stable or stable manure are too uncertain in strength to admit of any approximate estimate of the dilution required, and should not be used for plants in pots; but for crops in the open ground stable drainings diluted with six times the quantity of water, and drainings from a dunghill used pure, are very valuable. Fowl and pigeon dung make good liquid manure—1 peck to 30 gallons of water, well stirred up before use. Soot also at the same rate is a capital stimulant.

GLAZING WITHOUT PUTTY (J. H. L.).—We know of houses constructed upon the principle you name, and they answer perfectly, there being little leakage or breakage of glass.

GREENHOUSE FLUE NOT DRAWING (P. S.).—The flue is too narrow. It ought to have been 10 inches deep and at least 7 inches wide; and the chimney, instead of being 4 inches in diameter, should have been 5 inches. That, however, is not the cause of there being no draught; but supposing there had been a draught the flue and chimney would soon from the accumulation of soot have become choked. We apprehend that the flue is on a level with the furnace, though you show in the sketch a slight rise. The furnace, we presume, has an ashpit as deep as the height of the furnace, and extending the length of the grate and its width. If the bottom of the flue be on a level with the top of the furnace or nearly so, the flames and products of combustion have a clear rise of two-thirds the height of the furnace into the flue, it will draw so as to require a damper to regulate the draught, the flue having a gentle rise to the chimney.

UTILISING DEAD LEAVES (G. M.).—Decayed leaves are very valuable for all soils at all strong and deficient in humus. Fallen leaves are highly worthy of being gathered and employed as litter for cows and pigs, for when trampled to decay in such positions they form an excellent manure for most farm and garden crops. Soils to which they are not adaptable are those that are already light and rich by having had heavy dressings of decayed vegetable matter for many years.

HARDY VINE CULTURE (J. J.).—Plant the Vines in rows 5 feet apart and train the canes to single stakes 4 feet high. That is the way they are treated at Cardiff Castle. The stakes should be put to them immediately the growth is long enough to need securing, and the canes should be stopped at the top of the stakes. As to pruning, the first year there will only be one cane to cut back, and this should be cut down to three or four eyes from the bottom. When these eyes start into growth the following year the cane from each should be secured to the stake and be kept stopped at the top as before. In pruning them in the winter each cane may be cut down to a single eye, or two at the most, and when these begin to grow only four canes should be taken up as before, and as each of these canes produces two and three bunches a very fair crop is the result. This mode of pruning should be repeated annually. If your locality is exceptionally favourable you could easily try a few Vines on the west wall; they, however do not usually succeed on that aspect.

TEBBS'S UNIVERSAL STOVE (Poole).—Mr. Tebb's address, as advertised in the Journal of October 24th, is 98, Cheapside, London. The price of the stove varies according to size.

PYRUS JAPONICA (Arthur T. Webb).—The fruit is perfectly wholesome, and you may make marmalade of it in the same way as that of the Quince.

CHRYSANTHEMUM BLOOMS (James Brown).—We do not know of any nurseryman who would supply you with "Chrysanthemum blooms fit for showing." Why don't you grow them yourself if you want them for showing?

CHRYSANTHEMUM SHOWS (W. W. B.).—You will find a list of the shows now pending in another column, and the Secretaries' names, so far as we know them, in our record of coming shows.

PRIVET HEDGE (Subscriber).—The common Privet is suitable for a hedge, so also is the Japanese Privet, but it is much more expensive. When Thorn Quick is mixed with the Privet it seldom succeeds well, the Privet generally overgrowing it, and the Quick dwindles away. About three good Privet plants to a yard will form a good hedge, which may be planted at any time from November to March.

CAMELLIAS CASTING LEAVES AND BUDS (J. W. C.).—The cause is generally defective root-action, which may have been induced by a deficiency of water at an earlier date, by an excess of water at the roots, or by defective drainage, resulting in a sodden soil inimical to the health of the roots, which we apprehend are in an unsatisfactory state; but in the absence of data it is not possible to do more than hazard an opinion.

WHITE SCALE ON TACSONIA (Idem).—As you have tried many "cures" without effecting a riddance, we name one that with us is infallible, but it must not be applied to the leaves, but only to the stems with a brush. Half a pound of soft soap to half a gallon of water, to which is added a wineglassful of spirits of turpentine, thoroughly mixed.

ROSE BUDS NOT OPENING (Tyro).—The only thing required is more favourable weather combined with the plants not being allowed to carry too many flowers. Disbudding must be resorted to when fine blooms are wanted, but some lose sight of this, expecting perfect blooms irrespective of the vigour of the plants and the number of their flowers. Disbudding often makes all the difference between good and imperfect blooms.

MANURE FOR POTATOES AND TURNIPS (E. L. R.).—The best manures are farmyard dung at the rate of from 12 to 20 tons per acre, applying that for Potatoes in autumn or early spring, unless the ground be poor, when it may be applied at the time of planting, supplementing it with guano at the rate of 2 to 4 cwt. per acre. Phospho guano may be applied at the same rate. Dissolved bones or bone manure is the best manure for Turnips, applied at the rate of 2 to 4 cwt. per acre.

NEAPOLITAN VIOLETS IN POTS AND FRAMES (Violet).—Take up the plants at once with balls of earth attached to the roots, removing no more than the loose soil, and pot in rich soil, the pots being plunged to the rim in frames, or they may be placed upon shelves near the glass, be kept well supplied with water, and have air abundantly. The plants will flower well through the winter, frost being excluded. If planted in frames employ rich soil, and admit air freely whenever the weather is favourable.

PLANTING MARECHAL NIEL ROSES (A Lover of Rose Shows).—Presuming you intend to plant the Roses against walls, now is as good a time to do so as in March, protection being given to the shoots almost as readily as when the plants are laid in by the heels. If for planting in the open, which is not advisable except in very warm situations, planting would be best deferred until March. The plant against the wall facing west would be better if the pit lights leaned against it, and should be done now, so as to assist in ripening the wood by warding off rains and retaining heat.

ROSES, APPLES, AND PEARS FOR EXPOSED SITUATION (Jas. D.).—Roses: Alfred Colomb, Charles Lefebvre, Baronne de Rothschild, Madame Victor Verdier, John Hopper, La France, Lord Raglan, François Courtin, Sénateur Vaisse, Thomas Mills, Marquise de Castellane, Annie Laxton, Baronne Louise Uxkull, Bessie Johnson, Boule de Neige, Comtesse d'Oxford, Leopold II., Général Jacqueminot, François Michelon, Duke of Edinburgh, Dupuy Jamain, Marechal Vaillant, Madame Lacharme, and Thomas Methven, all Hybrid Perpetuals. Of Bourbons—Baronne Gonella, and Sir Joseph Paxton. Tea-scented—Gloire de Dijon. Apples: Dessert—Irish Peach, King of the Pippins, Cox's Orange Pippin, Margil, Reinette de Canada, and Sturmer Pippin. Kitchen—Lord Suffield, Cox's Pomona, Cellini, Golden Noble, Dumelow's Seedling, and Hambleton Deux Ans. Pears: Jargonelle, Williams' Bon Chrétien, White Doyenné, Comte de Lamy, Beurré Superfin, Marie Louise, Thompson's, Beurré Diel, Beurré Bachelier, Durondeau, Jean de Witte, and Bergamotte Esperen.

VIOLETS DISEASED (G. F.).—We have carefully examined your Violets, and find that the disease with which they are attacked is caused by a fungus called *Polyomyces Viola*.

CALCULFLOWER (J. J. L.).—We think you can obtain what you require from any seedsman advertising in our columns.

PROPAGATING LAVENDER COTTON (S. J. B.).—Insert the cuttings now in sandy soil in a cool frame, or preferably, perhaps, in gentle heat in spring.

NAMES OF FRUITS (M. G.).—1, Royal Russet; 2, Blenheim Pippin; 3, Royal Pearmain; 4, Golden Pearmain; 5, Brownless Russet; 6, not known. (C. R. S.).—Apple, Golden Pippin; Pear, Beurré d'Aremberg. (Ruffhams).—Formosa Nonpareil. (R. W.).—The Apple is Sops-in-Wine; we do not think its cultivation is confined to any particular district. (J. W. Lawrence).—Rousslet de Rheims.

NAMES OF PLANTS (G. M. U. C.).—Schizostylis coccinea. (W. W.).—Tropeolum pentaphyllum. (W. D. A.).—Ipomaea Quamoclit. (W. H. G.).—1 and 2, Scolopendrium vulgare vars.; 3, 4, 5, Athyrium Filix-femina; 6, Trierythra hirta. (—).—The scarlet flower is Cactia coccinea, the Composite Aster multiflorus. (C. F.).—Bryophyllum proliferum. (Connaught Subscriber).—The name of the shrub is, we think, Elaeagnus reflexus. (J. B. P.).—Cotoneaster serrulata. (G. K.).—The name of the shrub we were last week unable to identify is, we now find, Andromeda formosa. (J. C.).—Arbutus Unedo, the Strawberry Tree. (A. R. F.).—Coronilla Emerus.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

THE MANAGEMENT OF YOUNG CATTLE.

THE rearing of calves, as described in our article on the 23rd of May last, gave in detail the system pursued up to the time when the animals become as they are usually termed yearlings, or twelve months old. It is our purpose now to pursue the subject up to the time the animals are sold to the butcher or taken into the dairy as milch cows, which in either case may be accomplished with the most advantage at from twenty-four to twenty-seven months old. We propose to refer to the subject under two separate headings, each of which may, however, require subdivision. We will first allude to yearling steers intended to be fattened in the pastures or nearly so, and then give the method of feeding

entirely in the boxes or stalls. We will suppose that the steers become yearlings about the 1st of February, and they will require to be fed until the month of May, and treated as they had been since the month of October previously—that is, that they should be accommodated in a dry sheltered yard and roomy shed, the yard to be floored with earth or burnt clay and ashes about 8 or 10 inches in depth, the shed to be floored with the same material, but raised by several inches higher than the yard, so that the animals after the yard and shed have been littered with straw as cleanliness requires, may lie high and dry at all times in the shed. The shed, too, should be fitted with mangers 2 feet wide and 2 feet deep with divisions, and capable of holding fodder, such as chaff, cake, &c., as well as roots; and in order that the steers may feed without disagreeing we like to divide the shed and yard, with three or four rails, into pens for two, or at the most three animals, with 12 feet by 12 under cover free of the feeding path and manger, and 15 by 12 feet outside. In this way the animals always have the benefit of sufficient air and exercise to fit them for their future existence in the pastures during the next summer. The yard in front of the shed should be lowest on the outside, so that any excess of rain may pass away instead of keeping the pens wet and cold. In this way litter will be economised, whether it consists of clean straw, fern, or rushes. As the manure will be allowed to accumulate, soft sand or ashes should be strewn over the pens every other day, which will consolidate it, and improve the manure by keeping the pens drier both under cover and outside, and will effectually prevent any fermentation of the accumulating dung, which may then be allowed to remain until it becomes inconvenient or is required for use on the home farm. This course of management in the yards and sheds will be continued until about the 1st of May, at which time in ordinary seasons the grass land, if it is rich enough to fatten or partially fatten cattle, will be ready, for, unlike short feeding for dairy stock, it is essential that there should be a good bite of grass before the steers are turned in, and for a few nights before entirely leaving the sheds they should return in the evening and receive there the cake with mangolds mixed; but when they lie out in the pastures night and day it is a question of situation, for if the meadows are low without any high and dry brows for them to lie upon at night it is well to remove them from the low meadows, particularly if they are below the fog level, into a high and dry pasture, and there to receive their artificial food, as few pastures are rich enough to fatten the stock without it.

The method of giving the artificial food is of consequence, because some farmers merely place the cake in little heaps on the pasture and allow the cattle to pick it up clean, which they will do and eat the grass with it down to the bare ground; but it is a slovenly way, and we prefer to put the cake, &c., mixed with cut mangold into troughs, move them daily, and turn the troughs upside down when empty to keep them dry until the next feeding time. In giving artificial food a mixture of linseed cake and bean meal, or otherwise decorticated cotton cake (which does not require so much meal mixed), will answer a good purpose. On first going into the grass about 2 lbs. of cake and 1 lb. of bean meal mixed with about 10 lbs. of mangold for each bullock will be sufficient. The mangolds should be quartered into the cutter, the roots then will, after being passed through the Gardener's turnip cutter, come out in short pieces and well adapted for the meal and cake to adhere to. When eaten in this way it is done without waste and without scouring the cattle, as at this time of year the mangolds are ripe and in good order for feeding, and should be with care preserved for this purpose until midsummer, or at any rate until the early crops of roots, such as early turnips, cabbages, &c., are ready for use. This mode of feeding may be continued until the month of October, but as the grass becomes poorer in August and September the cake and meal may be gradually increased up to 4 lbs. of cake with meal 2 lbs. per day for each bullock. This will be necessary even where the grass land has been fed judiciously—that is to say, with some pastures laid up without feeding to get fresh, or with a constant change to fields of good grass. After being managed thus we expect them to have made good proof, and have continued in good health, barring any epidemic complaint like pleura or foot-and-mouth disease. We have particularly referred to the night lying of the animals in order to avoid if possible the black-leg or quarter-ill, which such young and thriving animals are liable to, although steers do not suffer from it so much as heifers under two years old. The mode of feeding also with mangolds and cake is especially adapted, being of a laxative nature, to prevent blood poisoning; the origin of the complaint is often accelerated, however, by lying in low, damp, and foggy places. During the first week of October we bring the steers to the home-stead, placing them singly in stalls or boxes. We prefer the latter, so that the animals may lie quiet and not disturb each other.

The foregoing remarks apply chiefly to the pasture feeding down to Michaelmas, after which time the animals will require to be fed during winter in the same way as those which have not been fed in the pastures all the summer. We therefore proceed

to state the plan of feeding those animals which are kept entirely under cover both in summer and winter, until they are fit for slaughter on the home farm or for sale to the butcher. After the root-feeding in the spring is over or partly over the earliest crops of rye will be ready, followed by trifolium, or vetches and oats mixed, as the case may be; but after the trifolium is gone we prefer to give clover, as we find it answers a good purpose, and it disposes of the clover crop without the risk and cost of making into hay, for we find that an acre of clover cut for soiling fattening cattle will make double the quantity of both meat and manure than when made into hay, and this refers to both the first and second crop of clover. When we commence feeding with green fodder, which we give *ad libitum* in the mangers, we still reserve a portion of mangold, with which we mix the cake and meal, and feed the stock twice a day, gradually increasing the quantity from 2 lbs. of cake and 1 lb. of meal, so as to give double the quantity of each at Michaelmas, from which time those steers which may have been to pasture and those which have been in the boxes will from that time all alike be put upon root-feeding, which will consist of first early turnips or carrots, then Swedes, and if required mangolds. Two feeds of roots per day are sufficient, the daily allowance of turnips being 65 lbs., of carrots 50 lbs., of Swedes 60 lbs., and of mangolds 56 lbs., always being passed through Gardener's cutter, and given mixed with cake and meal. At no period of the fattening process do we exceed 4 lbs. of cake and 2 lbs. of bean or barley meal per day, as the animals do not assimilate and return a proportionate profit when given larger quantities. No hay is given under any circumstances, and if none is given they never miss it; but the cattle will always eat a good quantity of clean oat or barley straw when fed only twice a day with roots, and will lie down quietly and digest their food. And let it be remembered that practically hay is not only unprofitable as food for fattening cattle but positively injurious. When fed as directed we have had both steers and heifers for exhibition as well as sale when slaughtered weighing over 96 stone (of 8 lbs.), being at the time under twenty months old.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour is still in connection with wheat-sowing and preparing the land for it. The drilling of winter beans should also be attended to if it has not already been done, and whether they are drilled, or dibbled, or planted under furrow, it is essential that good room should be left for horse-hoeing, &c. This being a fallow crop generally before wheat, the importance of complete intercultural cannot well be over-estimated; great care should also be taken to lay the land into ridges suitable to the soil, so that the water may pass away freely during the winter months, and to effect this the land furrows and water furrows also should be thoroughly made out, and even after that is done a man should, spade in hand, examine the water furrows after the first heavy rains in order to clear away any grit or sand accumulations. The carting and storing of root crops must still be continued if not already completed in order to avoid the damage by frost, which often occurs if storing is too long delayed; in fact, we are never sure of a season for storing roots properly. An instance of sudden and severe frost we well remember occurred in the autumn of 1859, in which season we had nine days of the severest frost we can ever remember before Christmas, and in this case it occurred during the second week in October. Very few people secured their mangolds in that year; enormous quantities were frozen and totally lost for consumption, except a portion used immediately after the thaw broke up. The frost was so severe that it stopped the ploughs and all preparations for wheat-sowing for upwards of eight days. This is certainly exceptional as to weather, but it should be remembered that our climate is full of surprises. The slug being so strong, the young plants of trifolium have in many instances been destroyed, and many farmers fancy it is too late to sow again, but we recollect an instance when the slug was very strong as at present, when we lost our first sowing of 20 lbs. of seed per acre. We then sowed 25 lbs. per acre, and that was destroyed by the same enemy; we, however, nothing daunted, knowing the value of the crop for spring cattle food, sowed 30 lbs. of seed per acre as late as the 13th of November, and this time it succeeded although so late, and we found that the night frosts stopped the slug but did not injure the young trifolium plants, and we had a bountiful crop, although it was rather later for use in the spring.

Hand Labour is yet employed in spreading manure on the clover leas, and if any threshing of corn by steam is going on men will be required to assist in the work and afterwards in tucking and topping the ricks. The odd horse will be engaged in carting away the chaff hulls and caving, as the case may be, to some place on the home farm, where it can be kept quite dry for use, otherwise these offals should be put into heaps and thatched, for the substances when mixed together as yielded by wheat, barley, and oats furnish chaff for various purposes on the farm without the labour of cutting hay or straw into chaff by the aid of machinery. The best time for thatching buildings is now; the straw being fresh is more enduring, and the placing of thatch where required, if done

now, may prevent further strippings of the roofs during gales of winter; the corn ricks also, to remain for the winter, if at all injured during the late gales of wind, should be repaired, and we must here remark that we find round ricks are able to resist the wind with less damage than oblong ones. The storing of root crops is still going on; this work should be let by the acre, so that women and children may earn money and forward the work of the home farm, for we have always found the work may be done cheaper by such labour with careful supervision than when done by men, besides the fact of teaching the young people to work on the farm—a matter which is growing in importance annually. The storing of Swedish turnips in the field in order to avoid damage by game or by the alternations of frost and snow may be done as follows:—Open with the plough a double veering—that is, throw out two furrows on either side, the last furrows being made deep. This will leave a space wide enough and deep enough to hold a large quantity of roots, and after being cast into the trench thus made the plough may turn a deep furrow on either side, which will partially cover them, and men with the shovel may complete the covering by casting loose earth from either side. The roots keep well covered in this way by earth only, especially where the land is dry, such as sand, gravel, or hazel loam. All kinds of live stock must now be prepared for winter feeding and winter quarters, more particularly where the supply of dead meat produced from the home farm, whether it may be beef, mutton, veal, or pork, is required at the mansion.

THE POULTRY CLUB.

A COMMITTEE MEETING of the Poultry Club was held during the Oxford Show, at which there were present the Hon. and Rev. F. G. Dutton (President), the Hon. and Rev. A. Baillie Hamilton (Vice-President), R. A. Boissier, T. C. Burnell, A. Darby, S. Matthew, Rev. W. Serjeantson, and O. E. Cresswell (Hon. Sec.). These were elected as members:—Thomas P. Lyon, 5, Fenwick Street, Liverpool, and R. W. Warner, Bellfield Lodge, Fallowfield, Manchester.

The disqualification of Mr. Burrell's Buff Cochins pullet in pen No. 81 at the Oxford Show having been brought to the notice of the Committee, statements by Mr. Burrell and Mr. Wragg, from whom he had bought the bird, were heard, and the Committee came to the conclusion that "Mr. Burrell when he sent the bird to the Show was unaware of the state of its hocks; and while the Committee entirely exonerate Mr. Burrell from any suspicion of dishonourable conduct, they consider he has shown a want of due care in exhibiting a purchased bird which he had not fully examined. The Committee decide that no sufficient evidence was brought before them as to the state of the bird when it came into Mr. Burrell's hands." The Committee next considered a complaint made against Mr. H. Feast, and passed a resolution—"A complaint against Mr. H. Feast, late of Swansea, having been taken before the Committee of the Poultry Club, Mr. Feast is requested to furnish his present address to the Hon. Secretary of the Club, Mr. O. E. Cresswell, Bagshot, Surrey, as the Committee have been unable to obtain it. Further action in the case will be taken at the next meeting of the Committee on Nov. 11th."

Mr. R. J. Wood's disqualification at Hemel Hempstead was brought before the notice of the Committee by the Secretaries of the said Show. The consideration of it was postponed to give Mr. Wood time to offer an explanation of it. The disqualification of Dr. Snell's Silver-pencilled Hamburg cock at Worcester was considered by the Committee, and a statement having been read from Dr. Snell that he "had purchased the bird from a person in Lancashire or Yorkshire," the Secretary was directed to obtain from him the name of the vendor, and further action in the case was deferred till the next meeting. Other minor business was then transacted, and a vote of thanks passed to the Oxford Committee for the use of their room.

THE OXFORD POULTRY SHOW.

THE seventh Oxford Show was held on the 30th and 31st ult. Fanciers always seem specially to enjoy the Oxford Show, and if we mistake not they did so more than ever this year, from the knowledge of how nearly they had been deprived of it. Considering the very short time between the granting of the Hall by the Corporation and the date of the Show, it was perfectly marvellous to see close on two thousand entries—good evidence of the confidence which the fancying public places in the Managing Committee. The weather was cold and cheerless, and we fear that in consequence the visitors were not so numerous as in past years, though crowds seemed trooping in on the evening of the second day. The birds were arranged much as in past years—viz., the poultry in the Corn Exchange, care being taken to give a light position in the gallery to the Ducks of bright colour; Ducks, Geese, and Turkeys were in a boarded annex, and Pigeons in the Town Hall.

Dorkings.—We think Dark Dorkings very forward this year, and the pullets specially good. The cup cockerel is an immense

bird, but with a twist in his comb, which we certainly do not like; his partner a capital pullet. The second pen contained a cockerel too long on the leg, and a nice pullet, lighter in hackle than winners generally are now, but much to our taste. We thought the third pen by far the best; the cockerel is immensely broad and massive, and their legs are white. The price of the pen was sixteen guineas, and we saw a sold card upon it, and understood that Mr. Burnell was the purchaser. Mr. Lingwood's very highly commended cockerel struck us as excellent in shape, and two pens, 8 and 10 (Taylor), contained good birds but too rusty in colour. Among Silver-Greys there were several very good pens. The cup pen was fine and silvery; second a short-legged thorough Dorking pair; third smaller but good in colour. In the Variety Dorking class a very pretty pair of Whites made their first appearance and took the cup. In the second pen, Whites, was a very forward pullet, but the cockerel had a bad comb and a small sixth toe on one foot. Third were tolerable Cuckoos.

Spanish.—The first and second pens were very near in merit, the cup pair being best in condition. In the third pen was a fair cockerel with a poor pullet. As a whole the class was not remarkable. Mr. Le Sueur's pens were empty, in consequence, we heard, of rough weather in the Channel.

Cochins.—The first Buffs were a grand pair, the cockerel quite gigantic, his only fault being paleness on the breast. Second cockerel nice in colour with too much tail; the pullet good in shape and even in colour. Third both well shaped, even, and rich in colour. There was much excitement about a disqualification in this class. Mr. Hewitt in examining a pullet under the impression that she might be an old bird, felt some broken or cut hock feathers, and thereupon disqualified the pen. It belonged to Mr. Burrell, the winner of the first prize in the class and of various other prizes. We believe Mr. Burrell to be a most honourable fancier and perfectly guiltless of any attempt at trimming; but whether the feathers had been accidentally broken or purposely curled, or so broken before the bird came into his possession two or three weeks ago it is impossible to say. Being a member of the Poultry Club he naturally wished the case investigated by the Committee of that body, with what result will be seen elsewhere in our columns. Partridge.—First a grand massive cockerel with a pullet very indistinctly marked and too high in comb. In the second pen was a better marked pullet, with a cockerel in the moult. Third a cockerel lovely in colour and in blooming condition, with a beautifully pencilled pullet. Blacks.—The cup pair glossy and in good condition but small. Second very large, but though they were in a capital light we could not see any gloss on them. Third bad in combs but probably good in colour, but in so bad a light that we could not see this. Lady Gwydyr's three pens all looked good in colour, and Mr. Darby's though rather young were splendid in shape. Any other Variety.—The Whites were not at all such a class as we have seen at Oxford. First fine birds, the cockerel rather yellow; second fair birds well shown; third fair, not well shown.

Brahmas.—Dark.—First a well-shaped large cockerel, and very prettily pencilled pullet. Second a cockerel with good black fluff, and a pullet with fine delicate markings rather mixy on the wing. Third a big cockerel and a pullet which we remarked at the Dairy Show, with black markings on a white ground. Light.—The cup pair fine and good all round. The second and third awards were incomprehensible. Second were very small, dumpy, and ugly in shape; third poor in shape and feather; fourth far superior deep-breasted, and good in colour.

Langshans had but eight entries. The first and second pairs looked gigantic. The cup went to their enthusiastic champion Major Croad. Langshan fanciers should rejoice at this.

Game.—The entries for Black Reds were very large. The judging did not seem to give satisfaction among Game fanciers. We seldom give much heed to complaints, but the Game fanciers generally seem almost unanimous in their choice of favourites, and so their opinion merits attention. The £10 cup went to a long cockerel but not in good condition. The second was generally preferred as better in feather and style. Third good in quality, but not up to the mark in colour. There were several fine birds beyond the winners. Among them, 173, commended (Pope), a little coarse in head; 178, highly commended (Wood), smart; and 181, highly commended (Nelson). The class was a good one. The pullets were again a large and good class of forty-eight. Cup very much like the Dairy Show winner, dull in colour but reachy; second better all round; third a smart pullet a little rusty; fourth very good in head and eye. There were several excellent birds among the highly commended. Many fanciers thought 209 (Garnett), the best pullet in the class; 238 (Etheridge) was worth a card. Brown Red cockerels were few. First good in colour but long in hackle. Second better taken all round. Third good colour in feather, red in face. The Brown Red pullets (21), were not thought well judged. First was only a middling bird, too golden in hackle. Third we preferred to second. 272, very highly commended (Fenwick), was as good as any in the class; and 269 (Colgrove), good. Any other Variety.—First cockerel a Duckwing, good all round; many judges thought him the best Game fowl in the Show. Second good in colour, rather

soft in tail. Third another good Duckwing rather high in tail; we think the Dairy Show winner. 283 (Colgrove), a good-looking Pile. In pullets first was a good Duckwing, dark in eyes; second a Pile which we should have put first; third a middling Duckwing. 805 (Andrews), a good bird. Undubbed cockerels numbered seventeen. First a Black Red good in form, inclined to be duck-footed. Second a promising Pile. Third a good-looking Black Red as good as any in the class. 308, highly commended (Matthew), another good Black Red.

Hamburghs.—We much liked the first Golden-pencilled cockerel for his lovely golden chestnut hackle; the comb of the second cockerel appeared to have been tampered with; third a cockerel with a splendid tail, but a coarsely pencilled pullet. Silver-pencils as a class looked out of condition. First a cockerel with good honest comb, his tail not fully grown; second a forward cockerel; third cockerel good in head, and pullet less coarse in pencilling than most pullets. Golden-spangles did not strike us as good. The first pair were stylish. First Silver-spangles a pretty pair, save that the cockerel's comb is set too far from his head; second heavy and good in mooning, but cockerel's comb uneven and his sickles backward; third well mooned. In Blacks we could not see any first-rate cockerel in a class of twenty-four. The first-prize pair were far too purple, and the cockerel had curious patches of gold on the wing; his head, however, is good. Second were moderate. Pen 391, highly commended (Garnett), were the best in the class, the pullet excellent in every point and the cockerel very good with the exception of a slight drooping of the spike of his comb.

Polands.—Gold had a class to themselves, and very good the winners were. First a pair which we admired at the Dairy Show. Silvers and Blacks were mixed. First were Silvers, with markings more inclined to spangling than are generally seen now; second Silvers; third Black, spoilt by a parting in the cockerel's comb.

French Fowls.—Houdans mustered twenty-nine pens. As a whole the class was good, the pullets generally better than the cockerels. The cup cockerel a large bird with fine round breast, not over-good in comb; pullet good, moderately dark in colour; second a very fine pullet, cockerel with enormous comb and poor crest; third a very dark pair, the cockerel's comb perfectly monstrous; fourth a good pullet. We wondered why pen 444 (R. B. Wood) was left out, and admired Mr. Boissier's pullet. **Creve-Coeurs.**—We think the breed is improving in form, and are glad to see them shown shorter on the legs. First a capital pair, cockerel's comb, however, sticking out too much in front of the head; the pullet in second pen looked as fine as the first; third a well-shaped cockerel with a poor crest.

Malays.—First a well-developed pair ahead of the rest, the pullet light cinnamon in colour; second and third not so forward, pullets darker.

Leghorns.—Most of the Brown cockerels were short of tail. The first very handsome in comb and carriage. Messrs. Fowlers' Whites looked oversown, and so were put behind others which in points they surpassed.

Andalusians.—The cup pen much grown since we saw them last, and now a very nice pair; the second and third were rather red in lobes. Several pens in this class were empty.

Silkie.—The first pair by far the best, specially in crests; the other awards we did not think felicitous, but several pens were very equal. Pen 542 (Dr. Macrae) contained two indifferent cocks and received a high commendation.

Sultans.—The cup pair by far the best; the second pair were five-toed, rather yellow, but with fine crests.

Any Other Variety.—First La Fleche, second Plymouth Rocks; third, Black Minorcas. 556, highly commended (Dugmore), White Rumpless.

Bantams were very numerous, 102 pens being entered. The cup Black Reds are very good, especially the cockerel, which combines smallness of size with good tight carriage; the second also are capital, the pullet even better than the first, though the cockerel hardly the equal of the first. Brown Reds were a small class. First a local pair, winning by condition, though not particularly good in points; second pretty birds, not smart enough. In the Any other variety Game fifteen pens competed. All the winners were Piles, the cup pen very good, the third in our opinion better than the second. Black Rose-combed numbered fifteen. This variety seem to us to get larger and larger; certainly they are now shown with magnificent lobes, but other points seem sacrificed for these. The first pair were easily ahead. Sebrights were not superior. First Silvers, the cock's comb very coarse; second Silvers, the cock a nice bird; third Golden, rather large. The cock in Mr. Leno's very highly commended pen a very pretty little Silver. Any other Variety.—First, a well-known pair of Pekins; we should much like to know their age and how many of the breed are left in the country. Second Cuckoos, well marked but large, we wondered at the award; third White Rose-combed. The class was an interesting one from the great number of varieties in it, some being very rare. Mrs. Holmes showed nice Black-booted, Mr. Dugmore White-booted; and Mrs. Brassey her famous Dark Japanese, not in their former blooming condition.

Waterfowl.—In Aylesburys Messrs. Fowlers' first drake is a

marvel. Rouens seemed a fine class, but were in a bad position to see their colour and markings. Pekins had thirteen entries. Mandarins and Carolinas had a class between them; first and third being of the former variety, second of the latter. Black East Indians were, as usual, beautifully seen in the gallery. First small, very good. Second capital in colour, but a little larger; next in our opinion came one of Mr. Kellaway's pens.

Any other variety.—First the Chiloe-Widgeon which won at the Dairy Show. Their colours are very soft and beautiful. Second, Viduats; third, ruddy Sheldrakes.

Pheasants mustered three pens. Nice long cages they had, still the lovely pair of fire-backed birds which won second seemed very uneasy and damaged their plumage a good deal. The Golden, which were second and third, were quite tame and at home.

Turkeys were heavy and good. Every pen noticed. Geese, too, were marvels for the year. Whites came in for the first prize. The usual Selling classes followed, but we abstain on principle from commenting upon them.

POULTRY.

DORKINGS.—Coloured.—Cup, T. C. Burnell. 2, S. Smith. 3, J. A. & M. F. Smith. *White.*—Cup, H. Lingwood, Countess of Dartmouth. *Local.*—1 and 2, F. P. Bulley. *Silver-Grey.*—Cup, T. C. Burnell. 2, O. E. Cresswell. 3, Countess of Dartmouth. *White.*—Cup, S. Salter. *Local.*—1, S. Salter. 2, H. Southam. *Any other variety.*—Cup, O. E. Cresswell. 2, Mrs. M. A. Hayne. 3, Countess of Dartmouth. *Local.*—1, H. Southam. **SPANISH.**—Cup, J. Powell. 2 and 3, F. Walker. *White.*—Cup, J. Woods. *Local.*—1, J. Powell. *Cinnamon and Buff.*—Cup, E. Burrell. 2, H. Tomlinson. 3, W. Nicholls. *Local.*—1, J. Gee. *Partridge.*—Cup and 3, E. Tudman. 2, G. B. C. Breeze. *Black.*—Cup, Mrs. S. Turner. 2, E. Kendrick, jun. 3, H. J. Storer. *Any other variety.*—Cup and 3, P. H. Chase. 2, R. A. Boissier. **BRAHMAS.**—*Dark.*—Cup, J. Wood. 2, L. C. Norris. 3, E. Kendrick, jun. 4, Rev. H. Buckton. *Light.*—Cup, G. W. Petter. 2, Mrs. Drummond. 3, R. Henderson. 4, Lady Kyrle. *Local.*—1, G. R. Morecraft. 2, Major Staples-Brown. *LANGSHAN.*—Cup and 3, Major A. C. Croud. 2, Mrs. B. Hinde. **GAME.**—*Black-breasted Red.*—Cockers.—Cup, Lieut. Col. Newdigate. 2, Hon. & Rev. F. Dutton. 3, S. Matthew. *Local.*—1, S. Field. 2, J. Hill. *Pullets.*—Cup, J. Halsall. 2, W. J. Pope. 3, T. P. Lyon. 4, S. Matthew. *Local.*—1, S. Field. 2, T. Penn. *Brown and other Reds.*—Cockers.—Cup, R. Taylor. 2, S. Matthew. 3, F. Warde. *Local.*—1, Mrs. Osborn. 2, Miss M. G. Wells. *Pullets.*—Cup, J. Taylor. 2 and 3, F. Warde. *White.*—Cup, J. Robinson. W. A. F. Fenwick. *Local.*—1, Mrs. Osborn. 2, Miss M. G. Wells. *Any other variety.*—Cockers.—Cup, S. Matthew. 2, D. Harley. 3, T. P. Lyon. *Pullets.*—Cup and 3, T. P. Lyon. 2, Capt. Walton. *Undubbed Cockerels.*—Cup, J. A. Nelson. 2, J. Colgrove. 3, Hon. & Rev. F. Dutton. *Local.*—1, E. Woodford. 2, Mrs. Osborn. **HAMBURGH.**—*Gold-pencilled.*—Cup, Duke of Sutherland. 2, G. & J. Duckworth. 3, J. Rawnsley. *Local.*—1, J. T. K. Castell. 2, J. Calcutt. *Silver-pencilled.*—Cup and 3, H. Beldon. 2, J. Rawnsley. *Gold-spangled.*—Cup, J. Rawnsley. 2, W. A. Hyde. 3, J. Blakeman. *White.*—Cup, Moore & Cartwright. *Silver-spangled.*—Cup, H. Beldon. 2, Ashton & Booth. 3, J. Lancashire. *White.*—Cup, J. Rawnsley. Rev. S. Ashwell. *Local.*—1, Rev. S. Ashwell. *Black.*—Cup, Stott and Booth. 2, T. Mallinson. 3, J. E. Smith. *White.*—Cup, Sidgwick. P. Hinde. *Local.*—1, W. D. Ward. **POLANDS.**—*Golden-spangled.*—Cup and 3, E. Burrell. 2, J. Rawnsley. *White.*—Cup, H. Jarvis. *Any other variety.*—1, E. Burrell. 2, G. C. Adkins. 3, T. Lecher. **HOUDANS.**—Cup, G. D. Harrison. 2, W. Nicholls. 3, R. B. Wood. 4, J. J. Scott. *Local.*—1 and 2, Rev. G. Day. **CREVE-CEURS.**—Cup and 3, T. Ward. 2, R. R. Fowler & Co. *White.*—Cup, R. B. Wood. G. W. Rhodes. *Local.*—1, F. Whichello. *Hens.*—1, J. Baker. 2 and 3, R. Fulton. *Young.*—1, R. Fulton. 2, J. Baker. 3, J. Chandler. **TUMBLERS.**—*Almond.*—1 and 2, R. Fulton. 3, J. M. Braid. *Mottled Short-faced.*—1 and 3, J. Baker. 2, R. Fulton. *Any other variety Short-faced.*—1, J. Baker. 2, T. C. Burrell. 3, H. Dacey. *Local.*—1, H. O. Crane. *Balds or Beards not Short-faced.*—

1, H. W. Bruno, 2, Cole & Bown, 3, J. Tanner, jun. *Any other variety*,—1, H. O. Crane, 2, J. Mallett, 3, Miss E. Beldon. **DRAGONS**.—*Blue*.—Cocks,—1, Cup, and 3, R. Woods, 2, R. & S. Leach. *Hens*.—1 and 2, R. Woods, 3, T. C. Burnell. *Young*.—1 and Cup, J. Lush, jun. 2, R. Woods, 3, C. E. Chavasse, *vhc*, R. Woods, T. Charnley, H. O. Crane. *Local*.—Prize, H. Crane. *Silver*.—Cocks,—1, W. G. Flanagan, 2, Hon. W. Sugden, 3 and *vhc*, R. Woods. *Hens*.—1, R. Woods, 2, J. Chandler, 3, W. Osmond. *Young*.—1, 2, and *vhc*, R. Woods, 3, W. Bishop. *Red or Yellow*.—Cocks,—1, R. Woods, 2, A. Leith, 3, W. J. Stapley. *Hens*.—1, Cup, and 3, R. Woods, 3, W. J. Stapley. *Young*.—1 and *vhc*, A. Leith, 2, R. Woods, 3, J. Tanner, jun. *White*.—Cocks,—1, J. Calcutt, 2, G. Parkham, 3, R. Woods, *vhc*, W. Bishop. *Hens*.—1, C. A. Pearson, 2, W. Bishop, 3, W. Boxall. *Local*.—C. F. Herrieff. *Young*.—1, C. E. Chavasse, 2, J. Calcutt, 3, W. P. Keall, *vhc*, R. Woods. *Any other variety*.—Cocks,—1 and 2, R. Woods, 3, T. C. Burnell, *vhc*, E. F. Woodman. *Hens*.—1, 2, and 3, R. Woods. *Young*.—1, 2, and 3, R. Woods. **ANYWERS**.—*Short-faced*.—Cocks,—1 and Cup, J. Kendrick, jun. 2 and 3, J. Bradley, *vhc*, B. Ravensley, W. B. Mapplebeck, jun. *Hens*.—1, F. Winsor, 2, J. J. Bradley, 3, H. Yardley. *Young*.—Cup, W. Slater. 2, H. Yardley, 3, J. Mantel, *vhc*, C. F. Herrieff. *Not Short-faced*.—1 and 3, C. F. Herrieff, 2, B. Ravensley. *Local*.—Prize, C. F. Herrieff. *Blue or Black-chequered Homing*.—Cocks,—1, B. Brown, 2, Cotton & Barker, 3, J. S. Pratt. *Hens*.—1, C. Herrieff, 2 and *vhc*, J. Hill, 3, W. E. Butler. *Any other variety*.—Cocks,—1, W. Cleave, 2, C. Hopwood, 3, Dr. E. Hicks. *Hens*.—1, F. W. Benham, 2, L. R. Williams, 3, W. Cleave. **RUNTS**.—1 and 2, H. Stephens, 3, H. Yardley. **OWLS**.—*Blue or Powdered Blue*.—Cocks,—Cup, 1, 2, and *vhc*, S. Salter, 3, J. Barnes. *Local*.—1, S. Salter, *Hens*.—1 and 3, S. Salter, 2, J. Barnes. *Any other variety*.—Cocks,—1 and 3, S. Salter, 2, J. Barnes, *vhc*, J. W. Stansfield (2). *Hens*.—1, J. W. Stansfield, 2, S. Salter, 3, J. Barnes. *Young*.—Cup, 1, 2, and 3, S. Salter. *Foreign*.—1, Dr. J. Bowes, 2, J. Baker, 3, S. Salter, *vhc*, M. Leno, jun. **TURBITS**.—*Blue or Silver*.—Cocks,—1 and 2, G. Webster, 3, C. Skinner. *Hens*.—1 and Cup, T. C. Burnell, 2, G. Webster, 3, S. Salter, *vhc*, J. Baker. *Any other variety*.—Cocks,—1 and Cup, J. Baker, 2 and *vhc*, T. C. Burnell, 3, S. Salter. *Hens*.—1, S. Salter, 2, O. E. Cresswell, 3, R. Woods. *Local*.—1, S. Salter, 2, J. Baker, 3, R. Fulton. *Any other variety*.—1, R. Fulton, 2, J. Baker, 3, R. Woods. **FANTAILS**.—*White*.—1 and Cup, O. E. Cresswell, 2, J. Waters, 3, J. F. Loveridge. *Any other variety*.—1, W. J. Warhurst, 2 and 3, H. Yardley. **NUNS**.—1, A. Duthie, 2, Miss E. Beldon, 3, R. Woods. **SWALLOWS**.—1 and 2, F. P. Bulley, 3, T. Wicks. **ARCHANGELS**.—1, S. Salter, 2, J. A. Winslow, 3, R. Woods. **JACOBSINS**.—*Red or Yellow*.—Cocks,—1, Cup, 3, and *vhc*, S. Salter, 2, J. Pyper. *Local*.—1, S. Salter. *Hens*.—1 and *vhc*, S. Salter, 2, R. Fulton, 3, J. Pyper. *Black or White*.—Cocks,—1 and 3, S. Salter, 2, J. Baker. *Hens*.—1, S. Salter, 2, J. Baker, 3, R. Fulton. *Any other variety*.—1, R. Fulton, 2, S. Salter, 3, C. Hopwood. **MAGPIES**.—*Black*.—1 and Cup, F. P. Bulley, 2, S. Salter, 3, H. Williams. *Local*.—1, F. P. Bulley. *Red*.—1, J. A. Winslow, 2 and 3, F. P. Bulley. *Any other variety*.—1 and 3, S. Salter, 2, F. P. Bulley. **ANY OTHER VARIETY**.—1, R. Fulton, 2, R. Gough, 3, J. A. Winslow. **FLYING HOMING**.—1, T. Taylor, 2, E. Newman, 3, Cole & Brown, *vhc*, J. Shillingford. **SELLING CLASSES**.—*Carriers, Pouters, or Short-faced Tumblers*.—1, C. J. Tutt, 2, C. F. Herrieff, 3, R. A. Pratt, *vhc*, H. O. Crane. *Any other variety*.—1, S. Salter, 2, R. Woods, 3, F. P. Bulley. *Pairs*.—Price not to exceed £3.—1, C. E. Chavasse, 2, T. S. Kemp, 3, W. E. Hutt. Price not to exceed £5.—1, R. A. Pratt, 2, J. Baker, 3, J. Chandler.

Mr. Hewitt and Mr. Teebay judged the poultry.

PERTH PIGEON SHOW.

THE first Show of the Perth Columbarian Society was held in the Drill Hall, a place well adapted for the purpose. The small prizes offered—viz., 10s. and 5s., in each class only succeeded in bringing together 132 entries. These amounts are rather too little to induce exhibitors from any distance.

Pouters cocks a good class of fifteen in various colours. First a Red, not good in colour, but with a large, well-shaped, and finely carried crop; a very showy bird in the judging pen. Second a stylish Red, deficient in crop, or would have turned the tables on the winner; third a good and well marked Blue; commended a Black (Semple), good colour and fair marking, but small; highly commended Red (Robb), closely marked, but stylish; Yellow (Webster), stylish, good colour, very deficient in feather. Pouter hens (eleven).—First good Blue, second and third fair Yellow, commended White. **Carriers**.—First a good style, and much superior to the rest. **Barbs**.—First and second fair Blacks, third a good Yellow, but red-eyed and washy in colour. **Jacobins**.—Winners all Reds, first and second being much ahead of the rest. Some good-looking ones were passed for being heavily plucked at the back of the head. **Short-faced Tumblers**.—A very good Agate first, an Almond second, and a fair Kite third, the rest very moderate. **Common Tumblers**.—First a Blue Bald, second a Black Bald, and third a Yellow Bald. The class as a whole lacked quality. **Fantails**.—First a really good, very small, and well-balanced bird with motion and style. *Any other variety*.—First a small well-gulleted African Owl hen of quality, second a good Black Swallow, and third a nice Red Turbit. **Selling Class** contained nothing of much value. Blue Turbits were first, second Red; and Black Magpies third.

PIGEONS.—**Pouters**.—Cock.—1, H. Fairley, 2, P. Wood, 3, A. T. Anderson. *Hens*.—1 and 2, T. Anderson, 3, A. Robb. **Carriers**.—Cock or *Hens*.—1, A. Stewart, 2, Carr & McLean, 3, J. Smart. **Barbs**.—Cock or *Hens*.—1, A. Stewart, jun. 2, G. Brothwick, 3, A. Smith. **JACOBSINS**.—Cock or *Hens*.—1, Carr & McLean, 2, W. & R. Davidson, 3, T. Mullions. **TUMBLERS**.—*Short-faced*.—Cock or *Hens*.—1, 2, and 3, J. Glenday. *Any other variety*.—1, H. White, 2, H. Fairley, 3, Robertson & Walker. **FANTAILS**.—Cock or *Hens*.—1, A. Smith, 2, Carr & McLean, 3, H. Semple. **ANY OTHER VARIETY**.—Cock or *Hens*.—1, W. & R. Davidson, 2, J. Glenday, 3, A. T. Anderson. **SELLING CLASS**.—*Pairs*.—1, J. Smart, 2, J. Glenday, 3, Carr & McLean.

JUDGE.—Mr. J. C. Lyell.

VARIETIES.

WE are requested to state that a Committee Meeting of the Poultry Club will be held at the Crystal Palace Hotel on Monday, the 11th inst., at 5 P.M., and the general meeting of the Club in the Crystal Palace at 3 P.M. on Tuesday, the 12th inst. A notice of this will be sent to every member and associate member, which notice will serve as a ticket of admission to the general meeting. In the case of any member not receiving or losing this notice, his or her visiting card will suffice.

— WE much regret to learn that the transept of the Crystal Palace in which we have been used of late years to see the Pigeons shown to so much advantage is at present taken up with some circus, and that consequently the Pigeons will be relegated to less favourable positions.

— WE hear that several of the best known amateur Pigeon fanciers have not this year entered at Birmingham, on account of the detriment their birds have suffered in past years from the suffocating atmosphere of the Pigeon gallery in Bingley Hall.

— WE have a report of a curious case tried in the Hull County Court. An exhibitor of a Pigeon in the selling class at the Cottingham Show sent a valuable bird, and, as is often the case, after winning with it claimed it himself. Another person also tried to claim it, and being informed that the exhibitor had already done so thereupon sued him. Judgment was given for the plaintiff on the ground that the bird was necessarily entered as for sale, which it could not be *bona fide* if the exhibitor had power to buy it in himself.

— AT the Council Meeting of the Bath and West of England Society and Southern Counties Association, held on the 29th ult. at the Grand Hotel, Bristol, Mr. Clement Bush, as Chairman of the Finance Committee, incidentally remarked that he believed that the loss sustained by the Oxford Meeting would not exceed £900, so that if an outstanding amount of £800 was speedily paid it would be unnecessary to draw upon the funded capital of the Society. The date of the Society's Meeting at Exeter was fixed for Whit week, commencing June 2nd, 1879. Colonel Luttrell, as Chairman of the Stock Prize Sheet Committee, brought up the list of prizes for 1879, which was approved and ordered to be circulated. The list showed an addition of £61 to the prizes offered at Oxford, caused by increasing the value of the prizes for Channel Island cattle, and adding a new horse class by giving prizes of £10 and £5 for yearling cart fillies. In the poultry prize list, brought up by Mr. Edwards, the principal alteration since last year was the addition of cups for the best birds in certain classes, and of another class for chickens hatched in 1879. Mr. Knollys, on bringing up the implement regulations for approval, reported that owing to the difficulty of obtaining land sufficiently near the show yard to be available for trial of steam ploughs, it had been determined to abandon such trials at the Exeter Meeting. Under these circumstances greater space would be devoted to the trial of sheaf binders, corn drills, and manure distributors, improvements in which it was highly desirable to encourage. The Devon County Agricultural Association were invited to join the Bath and West of England Society in the Exeter Meeting of 1879, but the Council were previously pledged to hold the 1879 Exhibition of the Devon Society at Devonport.

— RESPECTING the influence of machinery in agriculture, let us, says the *American Cultivator*, note two interests, wheat and cheese. Wheat is the great money crop of this country. Without the improved machinery now used in getting the 400,000,000 bushels of wheat annually raised in this country it would be impossible to harvest it, and there would not be a bushel for export. Cheese also is one of our large exports at the present time, and it is made almost entirely in factories. About 1851 the factory system of making cheese was first started. About 1855 it grew to a substantial industry. Its great growth was about 1865. In 1855 we exported 5,000,000 lbs.; in 1877 we exported nearly 200,000,000 lbs. It is hardly necessary to add that the growth and progress of the art applied to cheese-making has actually cheapened the product and enable us to export it in immense quantities. There is no doubt that the introduction of machinery into agriculture has cheapened the prices of products, and at the same time enabled us to compete successfully with other nations. In fact, breadstuffs are almost an industrial product, because without the recent agricultural machinery we could not compete in the price of grain with that raised by European labour.

THE STEWARTON SYSTEM.

MR. EDWARD THORP at page 306 tells us, "I have kept bees on a small scale for the last six years in skeps, and have derived much pleasure and some profit in so doing." This every bee-keeper can well understand; but the same gentleman, it would appear, is deterred from deriving enhanced pleasure and more profit by advancing to the Stewarton system through fear of a supposed enhanced outlay for hives and time to manipulate, which last he cannot well afford from his everyday avocations.

First as to cost. From Mr. Samuel Yates's (of Manchester) catalogue before me I find a full-sized Pettigrew skep costs 6s. 6d.; for a pair to hold a couple of prime swarms 13s. is incurred. A recent correspondent, "J. R.," tells us he procured 9-inch-deep body boxes from Stewarton at 5s. each, consequently he had his two prime swarms hived as one colony at an outlay of 10s., or at a saving of 3s. wood over straw, with the additional advantage that while the straw skep requires removal after a few seasons the wooden hive with ordinary care lasts a lifetime, and is consequently much the cheaper of the two. To obtain his income of

£5 2s. from his Stewarton colony "J. R." must have expended 2s. 9d. each, or 8s. 3d. for the three supers employed, but at the enhanced price of 6d. per pound super over run honey he was repaid thrice over, but their price was not deducted, as they would form part of his working plant, coming in serviceable for other hives and seasons.

Next as to time. My experience is most decidedly in favour of the non-swarmer or bar-frame over the swarming skep system. What a pleasant task is the look round the apiary of a morning, to put everything to rights before leaving for town, which is all that is required during the honey season. The business man cannot wait at home the middle or best part of the day to watch for skep swarms; that duty is delegated to some member of the family, who rolls it over on the gardener or some domestic, when neglect too often ensues, and our little favourites are voted all round a shocking bore. Take the case of "J. R." He said, "I hived my first swarm on the 17th of June, and lost much time watching for the other, which did not come off till late (12th of July)." Supposing this stock had been a frame hive instead of a common skep, the half of that cottager's breakfast hour any morning would have been amply sufficient to obtain an artificial swarm by simply placing a frame brood with the queen in an empty Stewarton on old stance, moving the stock close to first swarm, whereas he and his family lost their time and were distracted from other duties during a part of twenty-five days with what on an improved system could easily be accomplished in less than one half hour.—A RENFREWSHIRE BEE-KEEPER.

THE STEWARTON HIVE AND OTHER MATTERS.

WE have read that if two goats going in opposite directions meet on a bridge too narrow to allow them to pass each other, one kneels down to let the other pass over him, and that the goat which thus kneels is a finer gentleman than Lord Chesterfield. When two men ride together on one horse it is understood that one of them must sit behind the other. Though I have no Chesterfield pretensions and accomplishments, it is well known that I have for five years been playing the humble part of allowing others to pass over me. Very recently I tried to get on horseback behind the "RENFREWSHIRE BEE-KEEPER," with a view to do my best in helping him to introduce the Stewarton hive to the notice of the apianians of Great Britain. Strange as it may appear he would not let me. The offer of my services has been rejected without thanking; for my pains and good intentions I am grumbled at and found fault with. Some people are unfortunate and miss their way. A short time ago a lady at the head of a tea table asked me, "How it comes that so many writers on bees find fault with you while you do not find fault or interfere with them?" "Well, madam, answer me this question first: What makes all the sighing maids around pick at the pretty girl of the village?" "Oh, Mr. Pettigrew, you can get over everything and everybody," said the lady. Of course I can, and so can anybody else if he goes rightly to work. I am going to work in earnest to get over the "RENFREWSHIRE BEE-KEEPER." If I succeed in making him take the place of the humble goat on the bridge he will be a finer gentleman than Lord Chesterfield, and if he can humble himself to sit on horseback beside Mr. P. he would be a great boon to the apicultural world, and his fame would spread far and near.

I do not need to tell the readers of the *Journal of Horticulture* that the Renfrewshire gentleman is a faultfinder with almost everybody and everything out of his own school, that his criticisms are often severe and I feel unwarrantable, and that they are mixed up with personal allusions of a character not suitable for the intelligence of the present day. For five years he has been finding fault with me—almost everything I do or say is wrong. Mr. George Fox, the most successful gentleman in supering hives that England has produced, is found fault with. The day has past for large supers; the mode of filling them is wrong; the common bar-frame hive is wrong, its crown hole objectionable, and Pettigrew's lumbering waggon so full of great straw hives must be driven off the high road. Our friend down in Renfrewshire is fit for better work than this. There is a great deal of good stuff in him, and there is before him a wide field and around him a wide sphere of usefulness if he can abstain only from so much faultfinding, which at best is profitless work.

Some twelve months ago I had before me the letter of a lady seeking information about and a description of the Stewarton hive. I was greatly inclined to describe this hive in my own way, but being rather afraid of offending other folk I turned to Mr. Hunter's book, and there found a description of the hive from the pen of the "RENFREWSHIRE BEE-KEEPER," which I quoted. As the Stewarton hive still remains unknown to nine-tenths of British bee-keepers I thought it would be well for me to picture in words as well as I could this hive, and recommend it. Hence I wrote a description of the hive in question; and, sure enough, I could not write a better one now. Well, our Renfrewshire friend finds fault in his own characteristic way with almost everything I said about the hive. He says, "It is rather an unpleasant task to be required so frequently to demonstrate that Mr. Pettigrew is out of his

reckoning." I am fond of demonstrations of facts, and invariably pay far more attention to things proved than to things merely said. I may not know what he means by the word "demonstrate." If he assumes that somebody is wrong and he is right, and tells the world so, has he proved anything? I am not aware that he has succeeded once in proving that I have been wrong or out of my reckoning. I am anxious to avoid making mistakes, and whenever I discover that one has been made I openly withdraw it. The Stewarton was described as consisting of two breeding boxes 6 inches deep and 15 inches wide, with two supers 4 inches wide, all with cross bars. Our friend says "it actually consists of at least three boxes 14 inches wide, with as many honey boxes as are required." This correction is rather too frivolous to dwell upon. A bar-frame hive and a straw hive are what they are called without either supers or nadirs; and a Stewarton hive is what it is called without either nadir or super. If a Stewarton hive be ordered of Mr. Allan he sends two breeding boxes and two supers or honey boxes; if more are required he charges extra for them—I think 7s. for a box, and 3s. for a super. The "RENFREWSHIRE BEE-KEEPER" has, I think, been successful in filling supers on two boxes. As to the width of the hive being only 14 inches I have nothing to say. A friend of mine procured two from Mr. Allan last year—one of which was more than 15 inches wide—made to order. If a greater width be adopted, say 16 or 17 inches, the hive will be improved. The shifting of the slides, too, is a matter of choice. I said all were removed. Our friend says, "The slides are never removed from the tops of the breeding boxes to the tops of the supers, giving the bees free access from both first and second floors to the attics, which on no account is allowed." Again, "Mr. Pettigrew is far astray in stating that the queen can go into the super as often as she pleases. She is strictly debarred by the central slides being kept closed." Our friend knows, or should know, that if only one slide be withdrawn the queen can enter the super whenever she likes. Mr. Briscoe, who uses the Stewarton hive, lately told a correspondent seeking information that if three breeding boxes were not used the queen went into the supers. In determining what combs shall be used for brood the working bees appear to be the prime factors. My crown holes between hives and supers are 4 inches wide, and during thirty years I have found a patch of brood in two supers only. If ever I work on the Stewarton principle all the slides between hives and supers shall be withdrawn. Free access from all parts of the hive to the supers would tend greatly to prevent swarming. The Stewarton hive would not appear to me half so valuable if it could not be supered without the slide. Ample freedom and thoroughfare lessen complication and separation. In search of other demonstrations I shall have to take a retrospect. A few months ago "RENFREWSHIRE BEE-KEEPER" wrote in the *Journal* that a hive of bees was like a sealed book to those that do not use moveable-comb hives. How could he demonstrate this? Some fifty years ago I knew many working men who never saw a moveable-comb hive, and yet they knew a great deal about the internal workings of hives, and had then learned lessons which he has yet to learn. It is very painful for me to tell him this, but it is right that he should be told.

About the same period of time the question of crude and perfect honey was being discussed in the pages of this *Journal*, and it is well known that I hold there is a difference between them—that bees gather crude honey, and at home convert into perfect honey. Our friend pounced upon me like an eagle by declaring that Mr. Pettigrew's notions were "the crudest of all crude theories." I had seen, handled, and tasted both crude and perfect honey a thousand times, and could smile at the demonstration and let it pass; but seeing that he looks to his past doings it is just possible that he may consider that he put me right on the question. I think I can put him right. I intend going to Scotland next spring to remain some weeks. When I am there I shall be happy to visit his garden and let him, and as many bee-keepers as he may please to invite, have a demonstration. If he consents, I will turn up one of his hives and take from it both crude and perfect honey, and hand it to competent judges for examination, and leave them to say who is right and who is wrong. A demonstration of this kind would settle the question for ever; and by making arrangement for it our friend will show that he loves truth more than his own opinions. If the gentleman consents and makes the arrangements, and I live to go down to Renfrewshire, I shall beg leave to show him that he is wrong in stating that bees work in the day, and at night "enjoy a well-earned repose." What a treat it would be to me to see a swarm of bees asleep enjoying a well-earned repose! I think there will be no difficulty in showing him or anybody else that bees are during the night engaged in many offices of activity, one of which is carrying honey from the bottom to the top of the hive—from the breeding combs to the honeycombs, and that supers get great additions of comb and honey during the night.

On another occasion he stated that eggs were never removed from one cell to another. Many bee-keepers beside myself have known eggs removed from cell to cell after the queen was removed from the hive, and others have seen the bees in the act of removing them.

Within the last few weeks our Renfrewshire friend has found fault with me for not noticing publicly the capital results in supering off Stewarton hives belonging to a clergyman in his neighbourhood as I understood him, or living somewhere in Scotland. I am always pleased to notice and hold up to view the best models of success in every school of apiculture, but then I was comparing the results of the bar-frame and the Stewarton hives kept in England. At the time I had heard nothing of bee-keeping or harvests of honey in Scotland this year. Since then I have received three reports—two from Aberdeenshire and one from Lanarkshire, all pretty satisfactory. The Lanarkshire report comes from Mr. George Henshilwood, grocer, Carlisle. The bees there are the common sort, the hives are made of straw, and the swarming system is practised.

The report says that William Smith, station master, had a stock hive which yielded two swarms only. The parent hive weighed 92 lbs. and the swarm 131 lbs.—together 223 lbs. Daniel Reid had a first swarm rather heavier than Mr. Smith's. Mr. James Somerville (thatcher) got two swarms from one stock; weight of parent hive and its swarms being 296 lbs. Somerville had another stock which yielded—the first of which weighed 112, the second 94, third swarm 90 lbs. The old stock was not weighed, but his lightest stock was 56 lbs. and his heaviest was 80 lbs.; but taking the lowest figure for the weight of the stock, you will see that he got hives weighing in all 352 lbs. from one stock. James Rennie's hive produced the following results: stock hives 80 lbs., first swarm 70 lbs., second 35 lbs.; and two virgin swarms from first swarm. First virgin swarm weighed 100 lbs.; second virgin 43 lbs.; altogether 346 lbs. from one stock hive.

If the Renfrewshire gentleman would fairly consider these results I think they might help him to moderate his language in condemning other people, other systems than his own, common bees, and straw hives.—A. PETTIGREW.

P.S.—Since the above was written I have seen his letter on the Stewarton and straw-hive system, and regret much the strong feeling that is manifested by his remarks. As I am of opinion that angry discussion will not advance apiculture or settle any question of importance, it is likely that I shall not again attempt to defend myself from unfriendly attacks, meanwhile I court friendly criticism. I am very sorry that I mistook 1864 for 1868. It was quite unintentional. I trusted to my memory instead of referring to dates. However, the bees at Carlisle did as well if not better in 1868 than they did in 1864; therefore the mistake was in no sense misleading. I have to apologise to Mr. Briscoe for misreading his remarks and misrepresenting his meaning. This, too, was quite unintentional. I had discovered the mistake before his correction appeared.—A. P.

THE FERTILE WORKER.

TAKING a keen interest in entomology for a number of years, and having had a number of opportunities of inspecting live specimens of imperfect queens as well as hermaphrodites of the race *Apis mellifica* I was all the more curious to see what I had often read of but never chanced to meet with—a "fertile worker," which occurs in this species as well as in many of our wild bees, and more particularly after having perused the following startling assertion of your correspondent, Mr. A. Pettigrew—"I fearlessly affirm that there never was and never will be a fertile working bee." I therefore all the more gladly availed myself of the invitation of the "LANARKSHIRE BEE-KEEPER" to visit the apiary at Auchenraith, High Blantyre, and satisfy myself on that head, which I did on the 19th of July last. I was shown a queenless hive of common black bees, to which a piece of brood comb from an Italian hive had been given to raise a queen. This they failed to do. On the twelfth day the bee-master noticed a worker receiving marked attention, and on the following day found her depositing eggs. Three or four days thereafter grubs could be seen at the bottom of the cells, and he therefore made it a study to examine this hive daily. Seventy-one days from the time eggs were first noticed beautifully banded Italian drones emerged from the cells.

I can assure your readers it was with no small interest I watched her examining the cells, depositing eggs, and receiving that attention from the other workers usually given to royalty; her movements being all the more readily followed from her being the only Italian present amongst the black bees.—R. J. BENNETT, *Argyleshire*.

POSITION OF SUPERS.

FROM Mr. A. Cockburn's description of bee-keeping in the north of Scotland it is cheering to hear that the frame hive has found its way amongst northern skeeps. With combined swarms and modern improvements what magnificent harvests of super honey may we dwellers in a highly cultivated district expect to find recorded from that honey El Dorado Aberdeenshire in the second edition of Mr. Cockburn's sensible little treatise "The Scotch Bee-keeper!" with possibly, too, the chapter on Ligurian bees re-written.

Your correspondent's idea of placing the empty super below instead of above the full one is contrary to Stewarton principles, and, as I have already demonstrated, bad practice. He calculates immunity from brood therein by causing the bees to build thick comb. I once thought so too in my novitiate days, and the super safe with bars $1\frac{1}{2}$ inch wide, but afterwards made the mortifying discovery that all full-width combs were first narrow ones, and often brooded before they were elongated, and worse still, even after, our little favourites proved so accommodating as to cut down the lower portions of the wide combs to receive the souvenirs of the visits of royalty; consequently I came to learn to forge the fresh link always at the end of the chain; and, altering the phraseology a little, I would tender to your correspondent the advice once given to a friend of the writer, when doing the lions of the metropolis, by a denizen of the Seven Dials tapping him on the shoulder and, pointing to a little posterior handkerchief protrusion, remarked, "Don't, sir, put temptation in a honest man's way." And so say we, "Don't, sir, put temptation in a prolific queen's way.—A RENFREWSHIRE BEE-KEEPER.

OUR LETTER BOX.

GEESSE ON PASTURE (S. J. B.).—They will not kill the moss, and neither horses nor cows will feed where their manure is.

PAINTING BEE HOUSE (*Jane*).—We do not think it would be injurious to the bees to paint the outside of a house or hive at this season of the year.

METEOROLOGICAL OBSERVATIONS.

REMARKS.

30th.—White frost, few flakes of snow in morning, rain commenced 10 A.M.; fine after 0.30 P.M.; sunshine at intervals, dark and misty latter part of afternoon; fair evening.

31st.—Bright sunny morning, overcast and dull after 0.35 P.M.; fine with sunshine between 1.30 and 2.30 P.M.; dark and dull at 3.15 P.M.; drizzling rain at 4.30 P.M.; heavier rain after 6 P.M.; wet evening.

Nov. 1st.—Clear, fine, bright day; starlight evening.

2nd.—Bright sunny morning; short sharp shower 2.45 P.M., and shower at 3.35 P.M.; cold starlight evening.

3rd.—Fine day throughout; at times bright and sunny; lunar halo 7.30 P.M.

4th.—Misty morning, rain but only slightly from 9 to 10.30 A.M.; fair but dull; cold afternoon; moonlight evening.

5th.—Bright, clear, sunny day, rather warmer; cloudy evening with fine lunar corona.

A cold week; average temperature has fallen nearly 15° in a fortnight.—G. J. SYMONS.

COVENT GARDEN MARKET.—NOVEMBER 6.

EXTREME quietness has ruled our market during the week, common Apples being a complete drop, and high-class goods conspicuous by their absence. A plentiful supply of Pines from St. Michaels and Madeira have reached us, specimens from the latter place being exceptionally fine. Pears remain dear, the supply from the Continent being very short.

From observations taken near London during forty-three years, the average day temperature of the week is 48.8°; and its night temperature 33.8°.

PRUNING SHRUBS.

THE proper time to prune or cut-back trees and shrubs is a question often asked in the Journal. If experience warrants anyone giving an opinion on the matter I do not think that I need be afraid to state mine, as we annually do much of this kind of work.

Our pleasure grounds extend to between thirty and forty acres; nearly the half of this area is covered with trees and shrubs, and many cart-loads of stuff are cut from them every year. We cut them with two objects in view—the first to keep them in shape, the second to keep them within due bounds.

In cutting the shrubs into shape great care should be taken that this is not overdone, as nothing detracts so much from the beauty of a choice tree or shrub as cutting it into a formal cone. Our rule of cutting into shape simply consists of removing one of the leaders when two are forming, or cutting a few more points of one side than the other as the growth demands. In doing this we endeavour to cut without leaving any signs that pruning has been done. This applies particularly to single specimens on lawns, and isolated shrubs which stand apart from or above others in groups.

Cutting to keep shrubs within bounds is generally practised on Yew and other hedges, and on shrubs growing close to walks and flower borders and also in clusters together. Hedges may be clipped smooth like the face of a wall, but Rhododendrons and similar evergreens should be cut with the knife only and that just to remove the intruding points, leaving no stumps in a prominent position where only a surface of leaves or leaf-bearing shoots should be seen. Apart from this, however, the form and style into which trees and shrubs are cut will follow the owner's taste in many instances.

The time of cutting is of very great importance. In situations where the winters are mild and cutting winds do not usually prevail in the spring every kind of tree and shrub that will grow unprotected in the open air may be safely cut, clipped, or pruned from the beginning of November until the end of March. Cutting before November when the shoots may not be matured often causes them to die-back more or less from the wound, and to cut them when growth begins in April or during the growing season injures many of the more tender sorts. In districts where the winters are generally frosty and severe only shrubs of the very hardiest description should be pruned until the latter end of March, and by that time it is, as a rule, always safe to prune any kind of shrub as freely as is required.

The prunings of all kinds of shrubs cannot be more profitably disposed of than burning them; the ashes make an excellent manure for the kitchen garden. They suit all kinds of vegetables, and when mixed with a little soil they are excellent for covering Onion and other seeds.—PRACTICALIST.

ORCHIDS IN COLD FRAMES.

SINCE Mr. Gower found out by accident—the failure of a heating apparatus—that many Orchids would not only endure

a much lower temperature than was at that time supposed, but would thrive with but little artificial heat, the culture of these beautiful plants has considerably increased. A few years ago collections of Orchids were more rare than collections of Pine Apples are now. Orchids, however, are no longer limited to aristocratic gardens, but are now regarded as popular decorative plants, and are grown by hundreds where formerly dozens only were cultivated, and are seen in gardens large and small. They are grown in vineries, cool stoves, pits, and warm greenhouses associated with other plants, and in such mixed collections satisfactory results have been achieved. It is found that during the summer months many of the most free-flowering, useful, and beautiful Orchids in cultivation, such as *Odontoglossums* and *Masdevallias*, flourish admirably in houses having north aspects and where artificial heat is not afforded. This being so, it follows that there is nothing to prevent the plants succeeding equally well in unheated frames for four or five months in the year, or from the end of May until the middle of October. That many Orchids will succeed under this simple mode of culture, at least in the neighbourhood of London, Mr. Fisher, gardener to F. Williams, Esq., The Woodlands, Balham, has clearly demonstrated during the present season. On May 23rd Mr. Fisher placed a considerable number of small plants in 5 and 6-inch pots in a cold frame, and there they remained until the first week in October. I saw the plants shortly after they were placed in the frame, and again took occasion to inspect them just after they had been removed to the house after their summer sojourn in their humble quarters. The growth the plants made in the frame is of the most satisfactory character—fully equal if not superior to that made by plants grown wholly in houses. When removed from the frame the plants were remarkable for their healthy appearance, their sturdy growth, and fine brown pseudo-bulbs and robust spikes of bloom were showing freely on some of the *Odontoglossums*.

The frame was arranged with the lights sloping to the north. A portion of the soil was dug out to afford head room for the plants and to permit of a free circulation of air about them. Common flower-pot saucers were first placed quite level in the frame; in each saucer a flower pot was inverted, and on these pots the plants were placed. The saucers were filled with water, and were constantly kept so, the water answering two important purposes—namely, producing an atmosphere exactly suited to the welfare of the plants, and effectually preserving them against injury by slugs. A light framework was improvised 3 feet or more above the frame, and on this a canvas blind was spread to break the fierce rays of the sun during the height of summer. The canvas of course might have been laid on the glass, a mode of shading adopted by nine out of ten who shade plants in frames, but it would have been far less effectual: the plants require all the light possible, short of direct sunlight, and all the air they can have, and both are afforded by having the canvas supported some distance above the glass, where it acts more as a cloud than a direct cover. It is surprising how much better plants thrive when shaded in the manner above noted than they

do when the shading material rests on the glass. This remark applies to all plants requiring shade, also to Melons and Cucumbers; and those who try the plan will soon perceive its advantages: in the case of Orchids, however, Mr. Fisher considers the elevated shading not only desirable but indispensable.

The plants that have passed the summer in the frame at Woodlands are *Odontoglossums cirrhosum*, *Alexandrae*, *nebulosum*, *pulchellum*, *Insleayi leopardinum*, *membranaceum*, *triumphans*, *hastilabium*, *Phalaenopsis*, and *Roelzii*. All those except the two last named remained, as above mentioned, in the frame until the first week in October, the two specified having been removed a fortnight previously. Not one plant has sustained injury, but, on the contrary, all of them are in robust health, some having made remarkable growths. *Oncidiums Weltoni* and *cucullatum* were subjected to the same treatment and flourished equally well, while *Masdevallia Harryana* and *Epidendrum vitellinum majus* show by their rich green appearance how much they have enjoyed their cool summer quarters. It is Mr. Fisher's intention to subject other Orchids to the same treatment when the proper time arrives for doing so, he being satisfied that they will do as well, if not better, than if left in the houses.

The frame rested on the ground, all the air the plants received reaching them from the top, the lights always being tilted, often at the front as well as the back; they were also permitted to have all the sun they would endure, which, under the circumstances, was found to be considerable, the shading only being employed during mid-day in very bright and hot weather, and to this is to be attributed the ripe, hardy, brown, polished appearance of the pseudobulbs. The experience recorded demonstrates that with a judicious selection of Orchids and good cultural attention many can grow these plants and produce flowers of rare beauty who are as yet afraid of their cultivation, for it is certain that the sorts mentioned, and many more, only really require the convenience of frames in summer, at least in the south of England, and a house for wintering the plants having a mean temperature not exceeding 50°. Mr. Fisher is doubtless a skilful cultivator, for the plants under his care—not Orchids alone—are in excellent condition, clean and healthy, the *Crotons* especially being noteworthy for their fine foliage and bright colours.—J. WRIGHT.

GRAPES NOT COLOURING.

UNDER the above heading Mr. Iggulden has communicated some valuable remarks on an important subject. As a rule, I think when Grapes are deficient in colour the cause is exhaustion of the Vines—temporary it may be, and partial, still exhaustion. When Vines are overcropped the Grapes seldom colour well. They have not the necessary support enabling them to do so, or rather the resources of the Vines are so greatly divided that the several parts of the Vines cannot be perfected. If the same resources were expended on a lesser number of parts—bunches—in the same ratio would those bunches be improved. It is curious that if one portion of a Vine is lightly cropped and another portion heavily cropped, the Grapes in the one case will be black and in the other brown. This I have proved, and it is easy of proof by others.

When Grapes that are apparently moderately cropped refuse to colour, the cause even then, I think, cannot be found on any other principle than that of exhaustion—temporary in this instance and due to local causes, but still, I repeat, exhaustion. If a prolonged term of extremely hot weather occurs in the early part of the season Grapes are much more likely to be deficient in colour than if the heat occurred a month or two later. The cause of this, I apprehend, is that in the former case the feeding roots are less numerous than in the latter, while possibly the evaporation from the foliage may be greater earlier in the season than at a later period. Probably 90 per cent. of a bunch of Grapes is water; this is taken up by the roots and appropriated by the fruit. When the supply of moisture imbibed by the roots is not commensurate with the evaporation from the foliage then the Grapes must suffer, and the effects are seen in imperfectly coloured fruit. To counteract the effects of excessive transpiration a slight sprinkling of lime-wash to the glass is often advisable during brilliant weather in early summer before the roots of the Vines are in vigorous working order. It is not the bunches in that case that require shade so much as the foliage.

A high temperature is not essential for the colouring of Grapes. They will colour as well with a night temperature of

50° as with one of 70°; not so quickly, it is true, but quite as well, and probably better. This is obvious by the dark colour which Grapes assume when they ripen under good management in the open-air. At that time a long period of growth has produced a powerful root-action, and at the same time autumn dews arrest evaporation, and the fruit in consequence appropriate to the fullest extent the abundant nutriment supplied by the roots.

It is not at all uncommon for Vines that have produced imperfectly coloured Grapes in the summer to produce, if permitted, a second crop on the sub-laterals in the autumn with berries as black as jet. In the former case a thirsty atmosphere overpowered the roots; in the latter case, by the greater root-action then existent, the food supply was ample—there was no exhaustion.

A steady growth of Vines in their early stages is always an advantage, because the roots then have a chance to extend and gather strength before the crop is exhaustive. A long and steady growth is better than a short and quick one. This appears to be the opinion of "R. P. B.," whose writings have the true gardener's ring about them equally with those of "A KITCHEN GARDENER," who first directed attention to the significant want of finish of so many Black Hamburg Grapes this year, and of which I believe the true cause was suggested by Mr. Iggulden, whose letter is worthy of careful consideration.—A NORTHERN GARDENER.

RÉSUMÉ OF THE ROSE SHOWS FOR 1878.

My candid opinion is that the Roses exhibited this year have not been up to the mark: I mean that, compared with the exhibits of other years, the Roses shown both by nurserymen and amateurs have not been so good as I have known them. Secondly, I would say that what may be called the metropolitan growers have been at a discount. The honours have gone to the west both in trade and amateur exhibits. John Cranston is the king of rosarians this year, and Mr. Baker of Heavitree, Exeter, the first of amateurs. So three cheers for the west.

Perhaps someone will say Hereford is not in the west. If it is not, how is it that the West of England Rose Show is always held there? I suppose no one doubts that Exeter is the metropolis of the west, so that both with trade and amateur growers the west is this year victorious. Well, that is something. If you cannot claim yourself to be cock of the walk, you can say your big brother is; if you are beaten in Dorset, your neighbour in Devon is the biggest swell of all; if you do not astonish a cold cynical world with your exhibits, your champion in Hereford takes the shine out of all comers. So once more three cheers for the west.

The shows held this year have not been quite so numerous as of late years. Birmingham, which used once a year to welcome the queen of flowers, does so no longer; and Exeter from pecuniary difficulties is compelled to do without a show. On the other hand we have the two great shows of the National Society, but it must be remembered that one takes the place of the Crystal Palace exhibition; so that there is here only a gain of one, which is neutralised by the abandonment of the one held at the Westminster Aquarium. I do not know what reason has caused this, for at the dinner after the Rose and Carnation Show last July the manager assured us that he should always have a Rose show. As he gave this assurance in answer to a direct question from myself, I should be glad to know what has caused him to break his word.

The great Show held by the National Society at the Crystal Palace attracted most attention, and in my opinion it was undoubtedly the show of the year. The date of the fixture was a most happy one. Everyone was north and south, east and west. No one, as the Honorary Secretary wrote, can say that the date was too early, for we had a fortnight of the most forcing weather I ever knew in June, and the blooms opened at a marvellous rate. Many people who, like myself, have a hot light soil found that their Rose season was over in a very short time. A blaze of colour for a few days, a feast of Roses, and then all was over till the autumn. I remember well the Sunday next before the National, what a great quantity of bloom I had even on my wretched plants. I was able to send large baskets of Roses to my principal farmers and to all my friends, and the Sunday after I could not cut forty-eight distinct Roses, and was very hard pressed to stage thirty-six for Hereford. Mr. Baker's experience was much the same, though his blooms lasted longer than mine, but he was unable to show at Manchester on the 6th of July.

The season was one which suited Mr. Cranston to a nicety. His strong rich soil is one which can stand any amount of rain, so that the storms of May and the early part of June were a very godsend to him. "No one could come near him this year." This remark was made to me by one of his great rivals, Mr. Charles Turner of Slough, and I think most people will endorse it. Mr. Paul, it is true, did defeat him at the Royal Botanic Gardens, but this is the only time that I can recall where he was beaten at the great shows for the premier prize, for he did not show at the Alexandra.

The Crystal Palace Show was noted among other things for the advent of several amateurs who had not, so far as my experience goes, shown before at a great show. I had the privilege of judging the twelves and sixes, and I was much pleased with all the stands shown by Mr. Soames. This amateur bids fair to make it very hot for Mr. Baker and Mr. Jowitt if he goes on in the same way as he has begun.

The Teas, too, shown at the Crystal Palace by Messrs. Mitchell of Piltown, also at the Alexandra by the same firm, were the finest specimens I have seen for many years. I should have thought the Sussex soil too heavy for Teas, but Mr. Mitchell always comes to the front with them and rarely does much with Hybrid Perpetuals.

We amateurs this year did not show so well as usual. This is not my own opinion only, but that of such an experienced rosarian as Mr. George Paul. I cannot call to mind any stand exhibited in 1878 nearly so good as Mr. Baker used to show at Exeter and the Crystal Palace three or four years ago. It may be that as one grows older one expects more, but I do not think we have the intensely vivid colour that we once had. In form I think we are as good as ever.

In new Roses we are improving at a great rate. Scarcely a year elapses but each of the great Rose firms sends out one or more good Roses. If we run down the lists of Mr. Turner, Mr. George and Mr. William Paul, we shall find that at least three out of four of their seedlings have proved great acquisitions.

The success of the National Rose Society was very great both at the Crystal Palace and at Manchester; and all true lovers of the Rose must feel that this Society has already done a great work, has been the cause of the revival of Rose shows in the metropolis, and has issued a good set of rules on the important matter of judging. Much, however, remains for it to do, among other things one which has hitherto been neglected, but which formed one of the duties it undertook from the first. I allude to the matter of fixing the dates of the various shows, so that one may not clash with another. This is a very important matter, and one which ought not to be neglected. It must not be forgotten that such work as this is one of the obligations which the Society undertook, and though it may be a matter of difficulty to accomplish it, still we ought to do our best to bring it about. By the 1st of May a list of all the Rose shows should be published, and as far as possible these ought not to clash with one another.—WYLD SAVAGE.

PARSLEY IN OLD GARDENS.

It is quite a common occurrence for Parsley to fail in gardens which have been cropped with vegetables year after year for a quarter or half a century. Everyone who fails in obtaining a crop of any kind gives a cause for such failure in some shape or other, and no doubt I was like my neighbours in this as well as everything else. I tried every way that I could think of, three or four of which I will mention, and then give, in as detailed a form as I can, the plan I adopted at last by which I overcame the difficulty. It may not be anything new, but nevertheless it might by chance prove useful to some. First I trenched up an old Asparagus bed, added leaf soil, sand, and pigeons' dung. The Parsley seed germinated, but after the plants reached the third leaf they turned yellow and went off. Secondly I drew drills as if for Onions, on a fresher part of the garden as I thought. These drills were filled half full of a mixture of sandy loam, leaf soil, and a little soot, on which the seeds were sown, but with the same result as before. Thirdly, I sowed Parsley amongst the Onions, but no plants came up. Fourthly, I sowed on a prepared bed principally of small coal ashes. Abundance of plants came up, and grew pretty well until thinned, then yellowed off. Now for the successful experiment, and one which I have practised for four years without the slightest sign of failure.

My plan is to mark off a few 2-foot beds, and take the soil out of every alternate one to the depth of about 15 inches, the same as for Celery, only I wheel it away to some low part of

the garden, and fill up the trenches with alternate layers of fresh turf from the stock which is set apart for potting purposes and leaf soil—say a layer of turf 2 inches thick, and leaf soil half an inch, until the whole is filled up a little above the surrounding surface to allow for sinking. On this the seeds are sown and covered with a little fine soil about a quarter of an inch deep, then a gentle clap with the spade, and the whole is finished. A good plan is to cover the beds with bast mats in the daytime and remove them at night, particularly if the weather is dry; and this saves watering, and moreover the seeds germinate quicker. When the plants begin to crowd each other we give a good general thin-out; after is given a good soaking of water, in every two gallons of which we mix one wineglassful of paraffin oil. This destroys all insects which might chance to be in the soil, and imparts a beautiful green colour to the leaves. I have two beds of Parsley which were sown in July, and it is now a foot high, dark green, and splendidly curled. The variety is Myatt's Garnishing.—H. E. A.

LILICUM AURATUM.

THIS is undoubtedly a splendid Lily, and considering its great beauty, easy culture, and present cheapness it is marvellous it is not more generally grown. These considerations were suggested by seeing recently some splendid specimens planted and flowering in the open air at Marlfield House, the residence of John Bagwell, Esq., D.L., near this town. They were introduced a few years since by the Hon. Mrs. Bagwell, at all times a floral patroness, and planted out in a hardy Azalea bed, and have not I believe been since interfered with. As this is the season for the purchase of bulbs a few general remarks on culture and treatment will be *appropos*. Large bulbs are by many not so prized as medium-sized and well-shaped sound bulbs. I consider the deep peaty soil and leaf mould of the Azalea and Rhododendron beds tended much to produce the constant moisture around the roots, with that desirable shade of the natural habitat without which those Lilies will not come to perfection, not forgetting that long period of growth which bulbs not removed always enjoy. Some bulbs I have grown in pots and boxes could not compare with those grown in beds. The same remark applies to nearly the whole *Lilium* family, though many of them of more dwarf habit of growth and sweetly fragrant, as *L. lancifolium*, make handsome pot plants, especially when grown without forcing and for window decoration.

When intended for the conservatory or greenhouse procure the bulbs immediately—well shaped and sound; plant them in 6 or 7-inch pots for single bulbs, 8 to 10-inch pots for four bulbs, and so on proportionately. They are not fastidious about soil, but peat, leaf soil, and broken marrow bones form an excellent compost. It is important that 3 inches, or less in a small pot, should be left vacant at the top at first. Many place them away in the dark until the pot fills with roots, the same as Hyacinths or Tulips, but I have seen equally intelligent gardeners fully expose them in a frame to the light and succeed equally well. The object of leaving the space at the top is for earthing-up subsequently when the stems produce surface roots. Lilies during the period of active growth and flowering are gross feeders, and the roots should never be dry; plenty of drainage is indispensable, so as to avoid stagnant moisture. After the pots are filled with roots—not sooner—should it be considered desirable to have those ornamental plants early in bloom, they may be removed to a house where a higher temperature is maintained; if too high the stems become unseemly drawn, and the flowers last a comparatively short time. As a rule when thus grown they only suit for a handsome background, the flowers reaching outwards, and the stems, which are then rather long, being shaded by some other plants in front; yet remembering their great beauty, their time of flowering, and their fragrant perfume, no conservatory or greenhouse should be without them.—W. J. M., *Clonmel*.

PEAS IN NOVEMBER.

I FORWARD some Peas in a box of Hairs' Dwarf Mammoth. We gathered a very good dish this morning (Nov. 6th); indeed we have been gathering almost daily for a month past such as I now enclose. The Peas now producing so well were sown on June 19th in trenches of manure covered with soil. This method I find very advantageous for late Peas, securing them generally of good size and quality. Hairs' Dwarf Mam-

moth and Ne Plus Ultra do best with us. The latter sometimes makes a second growth, which is an advantage. I have sown it in April, gathered all the Peas clean off in August, and then it makes fresh growth and comes in excellent, especially should there be showery weather, which we frequently have in August. Mulchings are required in the absence of rain. I find Peas in November greatly appreciated, and consider them well worthy of the efforts made to produce them.—B. COWAN.

[The Peas received are excellent, the pods containing five and six fine Peas of full flavour.—EDS.]

A DAY AMONGST CHRYSANTHEMUMS.

CHRYSANTHEMUM SHOWS are unquestionably imposing, and are visited by great numbers of cultivators and admirers of this popular autumn flower. Thousands, however, who grow and admire Chrysanthemums are necessarily unable to visit the shows—they have to be content with reading about them, and of those a great number prefer to know something of the flowers at home—in what manner they are grown, and their appearance as arranged in the gardens where some of the prize plants are cultivated and winning blooms produced. The five collections to be briefly referred to are not selected because they are the best in the vicinity of London, but rather because they were convenient for being visited, yet all of them are so good as in all probability to secure a share of the honours that will be awarded during the next fortnight. The first collection visited was that of the Misses Christy at

COOMBE BANK.—Mr. Moorman is known as a successful cultivator of Chrysanthemums. Few gardeners know the varieties better than he does, and still fewer have such a good assortment of the Japanese section; he grows, however, equally well the ordinary Chinese incurved and reflexed varieties. The conservatory at Coombe Bank is wholly occupied with Chrysanthemums, most of them carrying prize blooms. The plants are all grown on the single-stem system, and have not been stopped. They vary in height from 3 to 5 feet, and carry about as many blooms. They are arranged on the floor of the house, the pots being placed close together, and the effect produced is extremely rich. The plants during the summer were placed in a row on the garden walk, the pots not being plunged, and no liquid manure was given before the buds were "set." Hard well-matured stems, stout but not exuberant foliage, and fine blooms are the results of that mode of culture. Amongst the finest of the Chinese section are Empress of India, grand blooms, yet very refined, and the new Golden Empress (clear primrose) is extremely well done. Very fine also are Mrs. Heale, White Queen, Mrs. Haliburton, the Beverleys White and Golden, and an improved Golden Beverley which is very rich; Aurea Multiflora, bronze and yellow Jardin des Plantes, White Globe and Barbara also all merit notice. The most striking of the Anemone-flowered varieties are Miss Ethel Boustead (an improved Lady Margaret), and Mrs. Pethers. Of the Japanese varieties, besides the pure white Elaine and the long-petalled Fair Maid of Guernsey, both fine and very useful, there are excellent examples of Emperor Nicholas, its reddish crimson petals tipped with gold; Gloire de Toulouse, free and fine; Fulton, the most brilliant yellow in its class, and for which Mr. Moorman had last year a first-class certificate; Fulgore one of the finest of the dark rosy purple varieties; Tokio and Mikado both very rich; Mons. Bijou, free, small, and brilliant in colour; Soliel Levant, very large yellow, a promising variety; also the large yellow, but not particularly attractive Peter the Great; the rich and elegant crimson and gold Madame Godillot (not a good grower), and one of the most useful of all, Triomphe de Nord. Those are a few of the more striking flowers of a very large collection, which affords sufficient evidence of Mr. Moorman's skill as a cultivator. The next collection inspected was at

KINGSTON-ON-THAMES.—Messrs. Jackson & Sons have been successful in introducing many new and good Japanese varieties, some of the more recent of which it will be useful to notice. The plants are grown similarly to those above noticed, and produce a fine display in the "show house." Harlequin is salmon pink in colour, distinct and very promising; Criterion, yellowish fawn, very large and very fine. Mons. Crousse, coral red, compact and good; Bouquet Fait, rosy pink, semi-quilled, attractive; Mons. Ardene, satiny rose suffused with lilac, flower 6½ inches in diameter, a fine acquisition; M. de Leaux, crimson red, yellowish centre, very large and deep; Mdle. Mouise, creamy white, distinct and very

good; La Frissure, bright rosy pink pretty crisped petals, free; Gloire de St. Martin, rose centre, changing to white with age, striking; Jane Salter, white petals, suffused and margined with lilac, chaste; Madame Lemoine, chestnut and gold, bright and promising; Madame Rendatler, salmon, broad petals; La Nympe, rose, small, free, and chaste; Jean de Leaux, after the style of Triomphe de Nord, yet distinct; Nuit d'Hiver, bright chestnut, gold tips, very large and fine; Fulton, Fulgore, and Red Gauntlet are all excellent; and Peter the Great has blooms perfectly incurved, which is remarkable for a Japanese variety; when not incurved the flowers are not attractive. Messrs. Jacksons' collection is both attractive and instructive.

CANNIZARO HOUSE.—This is the residence of J. Boustead, Esq., Wimbledon Common. Mr. Jordan, the gardener, is a skilful cultivator, and this year he has produced a display of Chrysanthemums of rare excellence. The plants are grown after the same manner as Mr. Moorman's—that is, they have never been stopped. It is evident they have had generous treatment, for they are remarkable for stout growth, rich green foliage, and grand blooms. Incurved and Japanese varieties are alike fine, and, if Mr. Jordan exhibits, those who defeat him will well deserve their honours. Although the plants have never been stopped they do not convey the slightest suspicion of "lankiness," many of them not exceeding 3 feet high; some are of course taller, but their general robustness obscures their height. Amongst the incurved varieties the following are remarkable for their size and high finish:—Leon Leguay, splendid; bronze and yellow Jardin des Plantes, Prince Alfred, White Beverley, all excellent; Dr. Sharpe, remarkably fine; Empress of India, Mr. Gladstone, rich; Mrs. Cunningham, a grand white; Mrs. G. Rundle, G. Glenny, and Mrs. Dixon. The finest Anemone is Miss Ethel Boustead, raised from seed from Lady Margaret, and considered superior to that variety. It is certainly fine, but whether really distinct can only be determined by actual comparison of the two when equally well grown. Of Japanese the old Triomphe de Nord is in grand condition, the blooms exceeding 6 inches in diameter. This Mr. Moorman states is the first Japanese Chrysanthemum that was introduced, and was originally classed by Mr. Salter as a reflexed Chinese variety; but if Elaine is a Japanese Triomphe de Nord cannot be excluded from the same section. It is a variety that all should grow. Equally fine in its way is Garnet, large, rich, full, yet elegant. Chang is remarkable for its singularly curled broad petals, exactly resembling mahogany shavings. Elaine, Fair Maid of Guernsey, Fulton, Fulgore, and Gloire de Toulouse all command attention, and some of the newer varieties are in admirable condition. Last year Mr. Jordan had to send plants to Wales to give an "object lesson" to some gardeners in the principality; this year the plants are equally good—are, in fact, splendidly cultivated.

BELVIDERE.—The large and good garden of L. Schlusser, Esq., is also at Wimbledon, and the gardener, Mr. Lyne, is admittedly one of the best gardeners in the district. He, like Mr. Jordan, has a splendid display of Chrysanthemums. Both in regard to excellence of culture and varieties they so closely resemble those above referred to as not to need a detailed notice. Mr. Lyne, however, stops his plants once, but they are not dwarfer than Mr. Jordan's, nor are the blooms finer, nor can it be said they are inferior, but are remarkable for their size and excellent finish. Mr. Lyne also grows Pompons well both as standards, pyramids, and bushes, and can, if disposed, arrange a group that his competitors would rather see "at home." It is an admirable collection.

TULSE HILL.—Of a different style of culture are the plants belonging to W. Stevens, Esq., at Springfield, and produced by the accomplished specimen grower, Mr. Hall. When these remarks are being read by the public on Thursday the 14th, the plants will be staged at the Brixton Show, and on their account alone, whether they win a prize or not, the Show will be worth seeing. They will also in all probability be staged at the Westminster Aquarium on the 19th inst., so that those who cannot see them at Brixton may see them in London. In growing Chrysanthemums Mr. Hall adopts the wise plan of growing a few plants well rather than a great number indifferently. For instance, he started with twenty-five plants, and twenty-one of them were worthy of a place in any exhibition. Perhaps the specimens of the large-flowering varieties are the more striking. They are in 11-inch pots. Larger plants have been grown, but rarely have specimens of higher quality been exhibited. Mr. Brunlee, Mrs. Haliburton, and

Faust are magnificent. The plants average about fifty blooms of high exhibition quality disposed with mathematical precision over the rich masses of foliage, which show them to such great advantage. The blooms are not more than 18 inches from the surface of the pots, and in form the plants resemble well-grown Pelargoniums. Mrs. G. Rundle, Mr. G. Glenny, Mrs. Dixon, and Lady Talfourd are also very fine. No other than the varieties named are grown in this section; but they are finished in a manner that places Mr. Hall high on the list of the best cultivators of the day. Like other really competent men the grower is "no churl," and in the *Journal* of December 7th, 1876, will be found a detailed account of how such plants are produced; the plant there figured, however, good as it is, is quite eclipsed by the specimens of the present year. The Pompons—standards, pyramids, and "flats"—are also remarkably well grown and trained. The former, Antonius, Calliope, and Mdlle. Marthé are on stems nearly 3 feet in height, and have well-formed heads about the same in diameter. Pyramids are also remarkably well formed and flowered, and the "flats" are not monstrosities trained pancake fashion, but are flattened half globes, good in foliage and blooms, excellently grown and admirably trained.

STORING POTATOES.

MR. TAYLOR'S notes on page 343 are seasonal. As a practical man he recognises the importance of selecting and carefully storing the seed tubers. That, I am of opinion, is of much greater importance than the change of seed so often recommended. This is just the time of year when seed Potatoes require special attention. The early sorts, especially if they have been stored in tolerably thick heaps, will now have commenced growing; and when once that is the case it is surprising how rapidly the sprouts elongate in their too often vain efforts to obtain light and air. If immediately the eyes are observed swelling the tubers are piled singly, as suggested by Mr. Taylor, in a light and cool place, where they are safe from frost, the eyes will move very slowly, and will attain great strength during the winter months. For more than twenty years I have adopted that plan with early Potatoes, and I have not in that time had a change of seed of what I deem the best variety; neither do I think I shall require a change if I grow it for twenty years longer, for it is certain that it crops fully as well as ever it did.

I have just been placing the tubers in their winter quarters. They have hitherto been in a dry shed, but are no longer safe there, and the swelling eyes too now require light—not the full clear light required by plants, but a subdued and moderate light, such as the light of a room. In a room lighted by side windows many tubers are placed in trays and on shelves, and others are placed in a pit where Geraniums are wintered, the tubers being placed (not spread anyhow) with their growing ends uppermost on the stage between the pots of Geraniums. By no other means known to me could that space be so well utilised. The tubers do no harm whatever to the Geraniums, nor the Geraniums to the tubers. A valuable variety of early Potatoes is well worthy of this care, and the tubers occupy their space quite as profitably as the Geraniums do theirs. The pit is not intended for ornament but for use, and is seldom entered by the family; yet I observe, if they do enter it, it is quite as much for the purpose of seeing the Potatoes looking, as they say, "so comfortable," as for inspecting the plants. My advice to all is, Look now to the early Potatoes, and store where they will improve, not deteriorate; for no more valuable crop than this is grown in any garden.—OLD ASHLEAF.

ROSE SHOWING.

Now that the National Rose Society have held their preliminary meeting and have settled the dates of the next year's shows, and we may suppose the various committees are thinking about the forthcoming schedules, will you kindly again allow me a little space to speak about classes for residents within a short distance of London and our other large cities?

Last season the plan was partly carried out by the National Society providing a class of this description for amateurs, but still the suburban nurserymen were left out in the cold. I do not remember any remark as to the corresponding class at Manchester, but it was said that the class for suburban-grown Roses at the Crystal Palace was almost a failure, the competition being very limited. The reason of this was, I believe, that the idea was a novelty, and scarcely anyone knew of it.

Several of my own friends were kept from exhibiting in this way, and as I did not obtain a schedule until two days before the entries closed I did not know myself if there was to be such a class or not. I know of plenty of amateurs in the suburbs of London who will be glad to compete next year if it is known beforehand that there is to be a class expressly for them, and so I want to ask that there may be a word about it in the advertisement that appears in the *Journal of Horticulture* some months before, so that we may prepare for it. And cannot we have a class of twelve blooms as well as six, and a small one, say of twenty-four singles, for the hard-working suburban nurserymen? If so, I believe such firms as Cutbush, Chamberlain, Ware, and others would gladly compete; but now if spoken to about it they say, "Oh! it's no use our competing with the great guns who generally show; they have ten times the number to select from, and far more favourable circumstances." If this plan were adopted I think the Rose would be in an exhibition, as well as other senses, the national flower indeed, but now it is merely a question of first, second, or third between about half a dozen nurserymen and the same number of amateurs, at least so it appears to the non-exhibiting but Rose-growing, Rose-loving public, and to—A LOVER OF ROSE SHOWS.

DRESSING CARNATIONS.

MR. DOUGLAS on page 347 attributes to me an unworthy motive, stating that my only object in raising a discussion is to "wound the feelings of a successful exhibitor." Why should I attempt to "wound" one with whom I have never competed and against whom I have not the slightest cause for enmity, or why should I write recklessly against those whom I have never seen? I did not assail the honour of Mr. Douglas in any way: on the contrary, I said that I did not for a moment suppose that he would do anything he thought was not right. But what he considers right others may deem wrong: hence the necessity for discussion. Mr. Douglas may not consider it wrong to have an expert to dress his flowers for him, and in that case he need not have been ashamed of answering the questions asked; but equivocation gives rise to unpleasant thoughts. I am told it is best to write to the secretary on the point at issue. Mr. Douglas must permit to say that he is hardly in a position to give me advice on the subject. What may be "best" for him may not be "best" for me; I therefore adopt my own course. As to the gentlemen named by Mr. Douglas not complaining, I have simply to say that it was not on their behalf that I wrote. There is yet a question I am requested to answer—namely, why Mr. Douglas defeated Mr. B. Simonite? I presume it was because the loam and air of Loxford are better for the flowers than those of Sheffield. I have had bitter experience of growing flowers on the skirts of a town only a little less black than Sheffield, and I am far more surprised at the cutler florist's success than I am at that of Mr. Douglas.

But the real point at issue must not be lost—scent must not be diverted by Mr. Douglas drawing a red herring across the track. The question is, Has not Mr. Simonite visited Loxford and dressed Mr. Douglas's flowers and thus aided him in winning prizes? If it is legitimate for great growers and dressers to unite their efforts to secure prizes it is only right and fair that the world should know it. It cannot be fair for such practices to be conducted clandestinely, and no exhibitor of repute can permit such a suspicion to attach to his name.

Some years ago when Mr. Douglas was defeated by an exhibitor of Hyacinths who had been aided by another in producing the prize plants your correspondent had justice on his side when he exclaimed, "The hand of Douglas is his own," &c.; but when he aids another to obtain a prize for Hyacinths, as he admits having done—for he has stated plainly that if "he had not dressed them they would have had no place in the prize list"—then even he must see that his words and acts contradict each other, and the public naturally ask for an explanation. I submit, and I know I am not alone, that the practice of one man aiding another to obtain a prize in whatsoever way it is done, whether by dressing Hyacinths or Carnations, is reprehensible. Overwhelming evidence has been afforded of the effect of dressing flowers in obtaining prizes; therefore at the least every exhibitor ought in common fairness to dress all his own flowers.

It appears to be convenient to Mr. Douglas to take no notice of anonymous writings. So be it, that does not affect me. So long as "WYLD SAVAGE'S" suggestion and my direct

question remain as they are, readers will form their own conclusion.—A STAFFORDSHIRE GROWER.

"C." SAYS (see page 352) it is "utterly incorrect" that I dressed certain Hyacinth spikes, but he says he "saw me lifting up the bells." Well, then, lifting up the bells is dressing Hyacinths. They must not only be lifted up but they must be evenly distributed over the spike, and they must be placed in such a position that they cannot fall down again. It takes longer to dress a spike of Hyacinths in that way than it does to dress two or three Carnation flowers, including placing them on the cards. As to whether the dressing improved the flowers in question, that is another thing. "C." says it did not—that it rather spoiled their appearance. With the other exhibitors I believe that dressing Hyacinths improves them for exhibition, just as it improves Carnations for the same purpose. It is five or six years since this case occurred, and I had nearly forgotten this fact until "D., Deal," asked the question, Whether, if one man dressed a stand of flowers and another grew them, who should be awarded the prize? Now I submit "D., Deal," should be able to answer that question, as they were his flowers that I dressed in the same way that I had previously dressed my own, and which also gained the first prize in a higher class on the same day. As to the question whether it is right for one exhibitor to help another there will always be difference of opinion. I have seen an exhibitor so hard pressed for time that, if he had not had some extraneous aid, his plants and flowers would have been left in confusion on the stage; and this, not because the exhibitor tried to do too much, but because you can seldom stage your plants or flowers when you are ready to do it. For my own part I do not care whom my opponents have to help them to stage their flowers, because the better they are staged so much more will the credit of this redound to the exhibitors as a body. It is also a fact that the system of florists aiding one another serves to promote that "utter abandon of good fellowship" alluded to by "A. G. S." last week, and that letters such as have recently been written serve only to engender discord. I number amongst my most intimate friends all the principal growers of florists' flowers north and south. They are at one with me as a grower and an exhibitor. I value the approbation of those men, and care not for critics who write for no useful purpose under anonymous signatures.—J. DOUGLAS.

[The question of one grower dressing the flowers of another opens a new phase in exhibiting and affords a fair subject for discussion. Such discussion can and ought to be conducted without acerbity. We have eliminated some remarks from the communications of both of our correspondents that did not bear immediately on the subject at issue, and which (we believe unintentionally) were calculated to cause pain and to provoke unpleasant replies.—EDS. J. OF H.]

CHRYSANTHEMUM SHOWS.

LAMBETH, PUTNEY, AND STOKE NEWINGTON.

LAMBETH.—Our notes on Chrysanthemum meetings commence with the Borough of Lambeth Chrysanthemum Society's Show, which was held on the 11th inst. This Society has not a long list of vice-presidents, patrons, &c., but is governed by men who, while following their daily avocations in the mill, factory, or workshop, possess that enthusiasm to grow their flowers in their spare hours in the midst of dingy courts and small backyards, hemmed-in on every side by bricks and mortar, and where the atmosphere is as thick and gloomy as in any part of our great metropolis. The plants and flowers are exhibited in a manner that is almost incredible, considering that the conditions are that "all plants and blooms shown for competition must be grown within a radius of one mile from the Elephant and Castle, Newington"—"That all blooms shown at this Society's exhibitions be shown as grown, and any exhibitor staging blooms with the flowers dressed artificially shall be disqualified from competition in all classes he may be exhibiting in." Such, then, are the conditions which this little band of workers have framed to guide them. The schedule of thirty-seven classes is so admirably arranged that we commend it to societies as a pattern; in fact, the whole working and management of this Society may be held out as a model worthy of imitation by societies of much larger pretensions. Every section of the Chrysanthemum is here encouraged by prizes similar to the following example: Twenty-four incurved blooms, distinct varieties, twelve ditto, six ditto; twelve of one variety, and six of one variety; also specimens, standards, pyramids, dwarfs, incurved, Anemone, reflexed, Japanese, and Anemone Pompons, are all encouraged in a similar manner. Uniformity and neatness exist throughout the Show—

the boxes are of one pattern and size, the labels are neat and written in one handwriting, and the cards indicating the prize-winners are neatly arranged at the back of the boxes with little clips to keep the cards erect. If the description of the class to which the prize is awarded was written under the prize ticket it would give additional interest to those exhibitors who are not familiar with the classes, otherwise the arrangements are almost faultless.

Mr. Summers has not only proved himself a gentleman of admirable organisation, but is a capital grower of both Japanese and incurved flowers; and in his collections there were many grand blooms, particularly among the Japanese. A bloom of Madame Godillot was the finest bloom in the whole Show, and acknowledged by many practical growers to be as fine a bloom as has ever been shown of that fine variety. Other good blooms in his collection were Gloire de Toulouse, Peter the Great, The Cossack, Fair Maid of Guernsey, Hero of Magdala, and Blanche of Castile. Although this collection was awarded the first prize Mr. Summers waived his claim in favour of Mr. Crisp, as his new residence is just outside the stipulated radius. In Mr. Crisp's collection Dr. Masters, Red Dragon, and Fair Maid of Guernsey were very good. Mr. Clark was second, and Mr. Addison third, all showing well. For six blooms Mr. Addison and Mr. Best shared the honours between them. The first prize for the best stand of six blooms of one variety was awarded to Mr. Best for Elaine, the second prize to Mr. Clarke for Fair Maid of Guernsey, and the third to Mr. Addison for James Salter. For twenty-four incurved varieties Mr. Wilsher secured the first prize and Mr. Best the second; and for twelve blooms, distinct, there were nine collections staged, Mr. Addison being placed first, Mr. Wilsher second, and Mr. Ball third. For six blooms, distinct, there were fifteen collections; Mr. Ball was placed first, Mr. Addison second, and Mr. Fill third. Mr. Ball was placed first for six blooms of one variety—Mrs. Dixon, Mr. Addison second with an old variety named Bella Donna, and Mr. Wilsher third with Gloria Mundi. Messrs. Fill and Crisp exhibited large-flowering Anemones, and the prizes were awarded in the order named.

Standards and pyramids were very neatly grown and trained by Messrs. Wilsher, Fill, and Clark, who obtained the lion's share of the prizes, and to whom great praise is due for the masterly manner in which the plants were grown, especially the ten plants trained by Mr. Fill, who was awarded three first prizes for them, and also obtained three other first prizes for cut blooms of Anemone Pompons.

Bouquets of Chrysanthemums were admirably arranged, especially the one to which the first prize was awarded, small buds being tastefully introduced between the flowers.

This was altogether a most attractive Show, and we congratulate the Hon. Secretary and his Committee on their well-won success.

PUTNEY.—During the spring of the present year a meeting was convened under the presidency of Baron Pollock, when the Putney, Fulham, and Wandsworth Chrysanthemum Society was formed, with the object of "stimulating the culture of fruits and flowers, and especially Chrysanthemums." An influential list of patrons was secured, a practical committee formed, and subscriptions collected, the latter being sufficient to cover the expenses of a show without depending on door money (a wise provision). The first Show was fixed for and duly held on the 12th inst. in the new Assembly Rooms, Putney. The schedule contained fourteen classes for Chrysanthemums, five for stove and greenhouse plants, and seven for fruit. The room was quite filled with the competing collections, which were generally of excellent quality so far as regards plants and flowers, but the fruit department was somewhat weak.

In the class for a collection of Chrysanthemums arranged for effect Mr. Harding, gardener to T. D. Galpin, Esq., Bristol House, Putney Heath, easily won the premier prize with vigorous plants carrying fine blooms. Mr. Andsell, gardener to G. Reid, Esq., Coombe Villa, was a good second; and Mr. Kendall, gardener to D. B. Chapman, Esq., Devonshire House, Roehampton, third for plants in which white stakes were fully too prominent. Mr. Pithers, gardener to C. F. Williams, Esq., Munster House, Fulham, was first in the large-flowered single specimen class with Mrs. G. Rundle—a half globe $4\frac{1}{2}$ feet across, and having about 150 blooms. Mr. Whittaker, gardener to S. Williams, Esq., was second with a smaller but admirably grown plant of Mrs. Dixon. Mr. Whittaker was first for six and four Pompons, and for a single specimen, with plants 2 to 3 feet across and excellently grown, also for four large-flowering plants in this class, Mr. Harding being second. Mr. Pithers was a good second for six Pompons.

Cut blooms were remarkably good—large and well finished, and had received little or no dressing. Mr. Harding was placed first for twenty-four incurved with a smart and excellent collection. Mr. Holmes, gardener to G. M. Story, Esq., who was second, was only a few points behind. Mr. Handley was third, his blooms being a little irregular in size, and an extra prize was awarded to Mr. Whittaker. The class for twelve blooms gave the Judges much trouble, and it was only by careful point-judging that the relative

positions of the collections could be determined. Mr. Harding and Mr. Bentley, gardener to Sir Thomas Gabriel, were equal firsts, Mr. Handley second, and Mr. Holmes third. All the blooms were good, those in the premier stands being of great excellence. For sixes the prizes went respectively to Messrs. Harding, Handley, and Kendall, and the Japanese to Messrs. Bentley and Kendall, all exhibiting well.

Mr. Pithers received the first prize for four stove or greenhouse plants with an excellent Eupatorium, a capital *Latania*, a good *Croton*, and a large and well-flowered *Salvia splendens*. Mr. Kendall was second, his noteworthy plant being *Vesuvius Geranium*, 5 feet across, dwarf, and well flowered. Messrs. Kendall, Milner, Distillery House, Wandsworth, and Pithers had the prizes for table plants, all being good, the first-prize collection especially so. The groups of plants (the prizes given by Mr. Stevens, St. John's Nursery, Putney), were remarkably good, the prizes going to Messrs. Kendall & Pithers, Mr. Whittaker's collection being highly commended. The plants were extremely clean, fresh, and well cultivated. Mr. Pithers had the first prize in the Miscellaneous class for a splendid collection of *Solanums* and good *Lycopods*, and Mr. Kendall the second for excellent stands of *Anemone Chrysanthemums*. Ferns were exhibited well, the prizes going to Messrs. Handley, Green, and Kendall, and Mr. Whittaker was first for small but well grown and flowered *Geraniums*, Messrs. Kendall & Handley won the prizes given by Mr. Moore, Richmond Nursery, Putney, for bouquets, which were very good, and a large group of *Chrysanthemums* and other plants arranged by Mr. Stevens were highly commended.

Mr. Martin, gardener to J. L. Ridpath, Esq., Devon Lawn, Wimbledon Park, secured the first prize for black Grapes with excellent Black Hamburgs, Mr. Milner being second with good *Alcantas*. Mr. Milner was first for *Muscats*, and Mr. Andsell second. Kitchen Apples were good, Messrs. Kendall, Milner, and Andsell being awarded the prizes. Mr. Maskell was first in the dessert class, and Messrs. Andsell and Milner had the remaining prizes. One very good collection was passed owing to the fruit having been polished, and was too greasy to be placed on any gentleman's table.

The Show was well managed by Mr. Moore, the Secretary, and was highly creditable to both officers and exhibitors. G. H. Pitt, Esq., an excellent supporter of the Society, presided at the luncheon, and the Society's first Show was as pleasant as it was successful.

STOKE NEWINGTON.—This old-established Society well sustained its renown by the great excellence of both plants and blooms staged in the Assembly Rooms on the 12th and 13th inst. We are only able to give a brief notice of the Exhibition. For the best collection of ten *Chrysanthemums* Mr. Monk, gardener to H. Head, Esq., Stamford Hill, secured the first prize and silver cup with exceedingly well bloomed plants of *White Venus*, Lord Derby, *Venus*, Mrs. Dixon, *Rifeman*, Prince of Wales, Mrs. G. Rundle, and *Pompons* Mdlle. Marthé, St. Michael, and a very beautiful plant of *White Cedo Nulli*. Messrs. Levesley & Co., Isleworth, were placed second with plants somewhat larger, but not so evenly trained and bloomed as the first-prize collection. Messrs. Dixon and Co. exhibited some immense plants in this class, but were disqualified on account of size of pots.

Pyramids of both the large-flowering varieties and *Pompons* were contributed by Mr. Prickett, gardener to Mrs. Bowerbank, Stoke Newington Green; Mr. Langdon, gardener to Dr. Munro, Brook House, Clapton; and Mr. Holmes, gardener to J. Hicks, Esq., Manor Lodge, Clapton, who share the prizes between them. Flat-trained *Pompons* were numerous exhibited. The first prize was worthily awarded to Mr. Monk for plants exquisitely bloomed and trained; Messrs. Levesley & Co. were placed second for larger plants, but wanting in finish; and Messrs. Dixon & Co. third with a remarkably even lot. Mr. Monk also obtained other first prizes for smaller-grown specimens.

The competition in the cut-bloom classes was very keen, and with very few exceptions the blooms were excellent. Mr. Langdon exhibited the best twenty-four in the Show, having beautifully grown and neat blooms of Mr. Brunlees, Empress of India, John Salter, *Jardim des Plantes*, *White Venus*, *Barbara*, Mrs. Heales, Mrs. Dixon, *Eve*, *Golden Eagle*, Rev. J. Dix, *Princess of Wales*, Prince Alfred, *Nil Desperandum*, *Aurea Multiflora*, Baron Beust, *Enamel*, *Lady Hardinge*, Mrs. Haliburton, Antonelli, Mrs. G. Rundle, *White Beverly*, and *Golden Eagle*. This collection secured the much-coveted silver cup. Messrs. Dixon & Co. were awarded the second prize, and Mr. E. South third. The best stand of twelve blooms came from Mr. Butcher, gardener to F. D. Lambert, Esq., Holly Lodge, Stamford Hill; Mr. Holmes being second, and Mr. Pricknell third. Mr. Butcher won first prize also for six blooms. F. J. Godwin, Esq., Downs Park Road, secured the first prize for twenty-four blooms among the amateurs; and Mr. Clark, Roehampton, was first for twenty-four in the open class, Messrs. Garraway & Son, florists, Bristol, running him very close for second honours. Messrs. Garraway were a long way ahead in the class for Japanese varieties, and in their collection they exhibited two of the finest blooms we have yet seen of a variety recently sent out by Lemoine named *Madame*

Berthier Rendatler. The pressure of visitors round the stands prevented us obtaining the names of the varieties. Messrs. Garraway also secured first honours in the open class for twelve and six blooms, which were both large and of good quality. Many other successful exhibitors deserve mention as having contributed well to this very meritorious Show.

NOTES AND GLEANINGS.

At the Royal Horticultural Society's Meeting next Tuesday there will be a fine display of *CHRYSANTHEMUMS* from the most noted growers, and a grand exhibition of vegetables is expected in competition for the prizes offered by Messrs. Carter, Sutton, and Hooper. Messrs. J. Veitch & Sons will by special request again exhibit an extensive collection of winter bedding plants similar to that which excited so much interest at the last meeting.

COMPLAINTS are frequent of the FAILURE OF CARROTS, especially when grown in the rich light soil of gardens which have been long under cultivation. Various modes of preventing the grub have been from time to time recommended, but still it remains almost as destructive as ever. Last week, however, we saw an instance of a splendid bed of Carrots produced in the simplest possible manner in a garden where it is utterly impossible to produce useable roots according to the ordinary mode of sowing the seed in April or May. The crop referred to is in the gardens at Belvidere, Wimbledon, and occupies the south border on the site where early Peas were grown. The Carrot seed was sown in July, and a finer crop of Early Horn (the roots being clean, handsome, and of the correct size for cooking) we have never seen. Previously to adopting the present practice Mr. Lyne was quite unable to produce clear roots, dress the land as he might; but by sowing in July he finds no crop more certain than that of Carrots. The same mode is adopted by other gardeners in the district with the same good results. The plan is worthy of trial by all who experience difficulty in growing this important crop. When sowing thus late it is necessary to grow early varieties, which are the best for table use.

At the ONION SHOW held at Limefield, near Bury, Lancashire, on the 5th October, Mr. Robert Houseman exhibited five Onions weighing 143½ ozs. There were two white and three red Onions, the heaviest being a red one weighing 34 ozs. It was 5½ inches across, 18 inches round, and 6 inches deep. The other reds weighed respectively 28½ and 27½ ozs. The two whites were respectively 27 ozs. and 26½ ozs. These Onions were all shown without their blades. The seed, which was of his own saving, was sown in February last, and the plants planted out in May.

We last year referred to some fine trusses of flowers of the brilliant scarlet *CLERODENDRON SPLENDENS* grown by Mr. Jordan at Cannizaro House, Wimbledon. We have recently seen the plant that produces a large and valuable supply of such trusses throughout the winter, and it is eminently deserving of notice, suggesting, as it does, how well the back wall of a stove may be occupied. The plant is planted out, and is trained on the wall of a lean-to plant stove about 20 feet long and half as much high. Every portion of the wall is covered with glossy foliage, and hundreds of rich trusses of flowers are just expanding. The plant continues producing trusses throughout the winter, and affords an abundant supply of cut flowers, which are justly esteemed for the decoration of vases. It is a long time since we saw the back wall of a stove utilised more profitably and attractively.

A NOTE from Northumberland informs us that *Ageratums*, *Calceolarias*, and *Vesuvius Geraniums* are still very fine there, especially *Ageratums*. *Dahlias* at the beginning of the present week retained their freshness. Snow had not then fallen, nor had the thermometer gone down to freezing point.

MR. WILLS has had printed a letter to Her Majesty's Commissioners for the International Exhibition, suggesting that a building for a COLONIAL MUSEUM for London should be erected at the south end of the Royal Horticultural Society's garden at South Kensington.

"M. M. S." recommends the following plan of PRESERVING SOFT FRUITS FOR WINTER USE which she has adopted for some years, and if the directions are properly carried out the fruit when used has quite the flavour of fresh fruit. The plan is this:—For Gooseberries, Currants, Damsons, &c., to each 3 lbs. of fruit add 1 lb. of loaf sugar, and one teacup of water to each pound of fruit. Put all in a preserving pan, and

let the ingredients come to boiling point. Have ready jars or bottles in which sulphur has been burnt for fifteen minutes. When the fruit is cold, pour on the top some hot mutton fat; then tie down with bladders, and keep the jars in a dry cupboard. Raspberries and Currants do not require so much water as stone fruit.

— THE new Orchid *DENDROBIUM SUPERBIENS* proves to be a valuable addition, for besides its handsome spikes of richly coloured blossoms, lasting as they do individually nearly three months in perfection, it appears to flower very freely. At Mr. William Bull's establishment a dozen fine spikes will be in bloom shortly, some of them with as many as twenty flowers on a spike.

— WEST OF SCOTLAND ROSARIANS' SOCIETY. — The annual meeting of the West of Scotland Rosarians' Society was held recently in the Oddfellows' Hall, Colquhoun Square, Helensburgh. There was a good attendance of members, including many of the most enthusiastic rosarians in the district. Mr. Galloway (of Messrs. Galloway & Graham) was called upon to preside. The annual report of the Society was read by Mr. John Mitchell, and the Treasurer's report by Mr. Barron, both of which were of a highly satisfactory nature, and, as usual, the reports were ordered to be printed and circulated among the members. Owing to the unprecedented success which has hitherto attended the exhibitions of the Society, and taking into account the liberal and hearty support which has uniformly been given to it by the inhabitants of Helensburgh and Gareloch, as well as by many patrons in other parts of Scotland and England who interest themselves in the cultivation of the Rose, the meeting unanimously resolved that the next Show should be held at Helensburgh in July, 1879. The schedule of prizes to be competed for on that occasion will be published with the annual reports probably about the end of December. The following are office-bearers elected at the annual meeting of the Society:—President, John Stuart, Esq., Provost of Helensburgh; Vice-Presidents, Alex. Barrow, Esq., Gowanlea, and John Few, Esq., Elmwood; Secretary, Mr. James Spalding, Princes Street; Treasurer, Mr. John Mitchell, Charing Cross, Helensburgh. Four Directors retire annually by rotation, of these three were re-elected—viz., Messrs. George Galloway, Irid Holm, Helensburgh; Daniel McLean, West Shandon; and Harry Lister, Inshalloch, Row; the only new Director being Mr. David Roberson, Helensburgh. The usual votes of thanks were cordially awarded to the Secretary and Treasurer for their services during the past year, and also to the Chairman.

— "C. T." writes from the neighbourhood of Petworth, Sussex: "Can any correspondent of the Journal say what is the largest *EUCALYPTUS GLOBULUS* growing in England out of doors? There is one here in West Sussex growing on the north-east side of a high wall; this winter will be the fourth it has been out in the open ground without any protection. It was 3 feet high when planted and is now 17 feet high, and at $1\frac{1}{2}$ foot from the ground the stem is 9 inches in circumference. As yet it has not flowered."

— HOUSE-TOP GARDENING.—We learn from the *City Press* that "some Maize (or Indian Corn) has recently been successfully cultivated by Mr. R. Oastler on the top of the house of Messrs. Jackson & Sons, 17, Sun Street. We have seen a couple of the spikes or ears, and one of them is remarkably well formed and full. This is the second attempt made by Mr. Oastler to raise Indian Corn on the top of a house, the first not having been successful; but the holder of several prizes from the City of London Flower Show was not to be deterred by a first failure, and he tried again and succeeded. During the past season we have seen some fine specimens of Figs, Strawberries (from the top of a warehouse near Cheap-side), and Grapes all grown in the City; and we believe Cherries have also grown and ripened 'within the walls.'"

GRAPES DECAYING.

NOVEMBER is generally admitted to be about the worst month in the year for keeping Grapes. With heavy autumn rains outside, and leaves decaying and falling inside, it is no easy matter to keep the atmosphere of a vinery dry, especially where the roof is not good and the heating power or drying agent deficient.

Few Grapes will decay if the air about them can be kept dry, except when the fruit is not well ripened.

As a first prevention of decay let every bunch be looked

over every day, and any berry showing the slightest sign of mould be promptly cut out. One decaying berry will often cause half a dozen others to decay in a single night; and if the weather be damp this half dozen will spoil the entire bunch in a couple of days. Another good plan is never to allow any decayed leaves to touch the berries or to lie long in the house. We are so particular about this that we pull off nearly all the leaves at the present time just before they fall.

When plants have to be watered in vineries it should be done in the morning, and, if possible, on fine days, when the ventilators at back and front can be left wide open for some hours afterwards. Ventilating to any extent should only be done on fine days, but unless the atmosphere is very dry the top ventilators should never be quite closed. When this is done, even during the night a dampness rises in the house and settles on the Grapes, causing them to decay rapidly. A little dry fresh air keeps the atmosphere clear and in motion.

When fires are employed to dry the house the temperature should only be raised to any extent on fine days, when the ventilators can be fully opened. A fire twice a week should keep a well-glazed house dry. To keep the pipes hot continually about this time is only a waste of firing. Those who have not thinned their bunches sufficiently will observe that where the berries are closest damping is worst. This should be a lesson to be remembered next year at thinning time.—M. M.

SCOTTISH HORTICULTURAL ASSOCIATION.

THE monthly meeting of this Association was held on the 5th inst. at 5, St. Andrew Square, Edinburgh. There was a large attendance, over a hundred members being present. It being the annual meeting of the Scottish Arboricultural Society many foresters attended. The President occupied the chair.

Mr. C. S. France read a paper on "Ornamental Planting." He said that the planting of trees was a science, and had been so from an early date, it having engaged the attention of the Greek philosophers. For embellishing rural scenery with the best objects of Nature they were indebted to Kent in the beginning of last century for having been among the first to lay down principles for guidance of the planter for landscape effect. He also touched upon the part which Bacon performed in realising the true beauties of the garden, spoke of the proper distribution of trees, and referred to the particular schools of landscape planting and their various peculiarities. The principle underlying the styles of the different nations was found in the outward features of each country. The primary rule to follow by all planters for effect was to imitate Nature. To have unbroken plantations and at other points vistas, so as to make the ground appear as large as possible, was an important principle to be borne in mind by all who plant to improve the beauties of the landscape.

Mr. Alexander Mackenzie read a paper on "Early-flowering Pelargoniums." He described the mode of propagation from cuttings and from roots which he adopts in the Warriston Nursery, and explained the treatment followed by him in every particular, from the cutting pot to the flowering specimen plant. The result of Mr. Mackenzie's culture of this valuable plant was that he had a house of them in excellent health bearing a profusion of bloom for twelve or thirteen months, a result which he could not produce with any other plant. The principal sorts of his collection were the following:—Madame Toulepeon, Digby Grand, Madame Lemoine, Triomphe de St. Maud, Bridal Bouquet, Annie, Fire King, Mrs. Bradshaw, Magnet or Marchioness of Lothian, Grandis, Floribunda, and Red Gauntlet.

Mr. James Gordon also read a paper on the "*Osmunda regalis*" in its native habitat at Camstraddan, where many acres of this much-prized Fern were to be found. He stated the different conditions under which it luxuriated on the banks of Loch Lomond, the fronds attaining the length of 6 feet.

Messrs. Dickson & Co. exhibited flowers of the *Schizostylus coccinea* fully expanded, growing in the open air, and blooms of *Veronica speciosa* and *Violas Golden Gem* and *Lilacina*. Messrs. Todd & Co. showed flowers of the crimson East Lothian Stock. Mr. Henry Kintoul sent blooms of *Vallota purpurea* in great beauty at this season, and Mr. Chisholm sent some Gooseberry roots infested with a parasite. Mr. George Donaldson sent a new seedling late kidney Potato, which was highly commended by the New Vegetables Committee.

TOMATOES.

I QUITE concur with Mr. Harding respecting the advantage of growing Tomatoes against walls. For the past five years I have grown Tomatoes under glass and in the open for market. Last year I planted about two hundred plants against a south wall, and I had not a dozen diseased fruits to the hundred. The variety was an old one, name unknown. Up to the last two years I have been very successful, but this year and last

the crops have been nearly a failure. Last year I lost all except those I planted against a wall. This year on June 1st I planted two hundred plants, half of them in the open and the others in frames. For the first four or five weeks the plants in the open and tied to stakes grew remarkably strong, having every attention they required. On August 12th I noticed just as they began to colour the disease also appeared on some of the finest fruit. All the plants were strong and healthy. Out of fifteen bushels gathered there was not more than one bushel saleable. Those planted in the frames fared but little better, although every care was taken to keep them as dry as possible. Several other growers in the neighbourhood were in a similar position; one in particular planted about four thousand plants in the open field, and the lot was quite a failure. Can anyone of your readers inform me if plants plunged in pots will prevent disease, the growths being trained on a trellis either in a house or frames?—**AMATEUR.**

THE EUCALYPTUS IN ALGERIA.

I HAVE seen an interesting notice of the growth of the *Eucalyptus globulus* at Muckross Abbey in the *Journal of Horticulture*. It is but right that some effort should be made to popularise this tree in Great Britain; and at a time when we have become possessed of the Isle of Cyprus, renowned in antiquity for its fertility, and that fertility has been seriously interfered with by the ruthless destruction of its forests, it may not be amiss to bring before your readers some information gathered specially for their benefit within the last few days, so that they may know somewhat of the plant which is being so extensively cultivated in Algeria at public and private expense. The reason that guides its cultivation here is that which will guide the English to plant it in Cyprus.

Algeria at the time of the Roman occupation abounded in forests (springs of water were not so rare then as now), but the Arab came, and with his race gradually fell the timber, never to rise again, for the Arabs thought not of the morrow, and planted nought. The French in 1830 found Algeria a wasted treeless desert country, but guided by the fact that to plant trees is to make a country healthy and fit for colonisation they planted the Mulberry, the Plane, and the Cypress. A tree of quicker growth, however, than these was needed, and was found in the *Eucalyptus*.

To the discovery of the *Eucalyptus* the French lay claim in the person of an officer of the French naval service, himself a distinguished naturalist, who was attached to an expedition which anchored off Tasmania in 1792, by name Labillardiere. The French do not seem to have in any way utilised the discovery of the tree, which has been brought to the front more by the growth of our own Australian colonies than aught else.

In 1854, through the exertions of a Mr. Ramel (a Frenchman), seed was sent over, and the tree propagated in France, and it would appear that through his constant writings respecting its hygienic and medicinal properties it began to be looked upon as likely to play an important part in creating forests in Algeria.

In 1863 Mr. André, gardener in chief to the city of Paris, wrote pointing out how, notwithstanding its rapid growth, *Eucalyptus globulus* is denser than any other wood, its specific gravity exceeding even Teak; and recently we find India, the country of the Teak, drawing immense supplies of *Eucalyptus* timber from Tasmania, principally for railway sleepers. Public attention having been thus drawn to the tree, a Mr. Trottier in 1862 first caused some plantations to be made of it on his property near Algiers, and very soon the valuable properties it possesses showed themselves.

Rapid growth in a country denuded of trees has hastened its general introduction. An *Eucalyptus* (Blue Gum) grows some 19 inches per month in its first year, provided the soil be rich and suitable. At ten years of age the trees will be 55 to 60 feet high, and at the ripe age of one hundred years may even reach 300 feet, which is the height of some actually measured in Australia, while the diameter close to the soil was found to be 30 feet. Add to this wonderful growth the persistency of its leaves, and in this country—where the hot wind of the desert blows with terrific force, often at 107°, as I have felt and tested myself—it can be readily seen how the thoughtful farmer by planting to the south and west of his crops creates a wind break of immense value, while at the same time he is growing the materials for future use in erecting his farm buildings, for sale as telegraph poles or railway sleepers, &c.

The principal planters of the *Eucalyptus* outside the govern-

ment are Mr. Trottier, Mr. Cordier, Mr. Arlés Dufour, La Société Algérienne, Mr. Playfair, and the Railway Company.

Mr. Trottier has some 93 acres of flourishing plantations, a great part of which are close to Algiers, and worthy a visit.

Mr. Cordier planted his first two trees of *E. globulus* in 1863. Since 1864 his faith in the future of this tree is so great that he has annually planted some two thousand, either in blocks or in lines, so that at the present time he is owner of some twenty-five thousand thriving trees. In April, 1876, Mr. Cordier made out a list showing that he had growing on his plantations 119 different species, and I believe he is engaged noting carefully and experimentally the different soil each requires, which are suitable for growth in the plain or on the mountain slope, which species will bear drought, and which requires humidity.

Supposing the English Government required to plant *Eucalyptus* in Cyprus, there is no man here except our indefatigable and learned Consul, Lieut.-Col. Playfair, so well fitted to advise upon the proper species to plant, &c., as Mr. Cordier.

The plantations of Mr. Arlés Dufour are situated about the centre of the plain of the Mitidja, in what was formerly a marshy district, and it was more particularly with the object of modifying the force of the south-west winds as they passed over his lands that this gentleman has bestowed such a large amount of care and attention to the culture of the *Eucalyptus*.

A few days ago I drove from the seashore across the Sahel, or low mountain range separating the plain from the Mediterranean Sea. As the summit is reached, the road making a sudden bend discloses to view the magnificent panorama of the Mitidja plain. From the vast expanse of burnt-up earth and waste land as it appears after an Algerian summer the eye instinctively sought relief by resting upon a great mass of dark green vegetation, the oasis of this apparent desert.

This mass of foliage marked the *Eucalyptus* plantations of Mr. Arlés Dufour, arranged as vast curtains formed of twenty thousand trees to form the wind breaks I have already spoken of. Away in the distance could be distinguished the site of the Arab village Benit Amoo, marked by its proximity to Orange groves and an *Eucalyptus* plantation, the property of the son of our Consul Lieut.-Col. Playfair, who is about to devote his energies and agricultural education more particularly to the farming of the *Eucalyptus*, which is expected to yield handsome returns on the investment.

Further away still is the town of Bonjurik, marked by its groves of magnificent Plane trees and the *Eucalyptus* plantations of Mr. Gros and others. La Société Algérienne have three plantations, one of ten thousand trees on the borders of a lake, two others of respectively ten thousand and twenty thousand trees. Of these a third average seven years of age, and are now being cut down, and find a ready sale as telegraph posts, supports for mines, &c.; *globulus* and *resinifera* are the two species cultivated by them. Acting for a second party the same Company have elsewhere plantations of one hundred thousand trees each. The Railway Company count on the borders of its line some four millions of trees, the majority now being *Eucalypti*. A few parts of the line remind one of the grateful shade afforded those who travel in America by the forest trees through which the iron horse ploughs his way.

Considering that it is only some fifteen years since the planting of the *Eucalyptus* tree commenced in earnest, it may be considered an evidence of successful introduction when I inform your readers that the total number of trees at present in growth is estimated at not less than 1,500,000.—**ARTHUR TODD, Algeria.**

ANNUALS AS CUT FLOWERS.

ESCHSCHOLTZIA CROCEA FLORE-PLENO.

I GROW a good quantity of the branching *Larkspur* mainly for supplying cut flowers during the autumn months, not that it is unavailable for this purpose earlier in the year, as, in fact, it comes into bloom in July; but it is at this season that a call for an increased quantity of cut flowers is made on us, and some of the varieties of this *Larkspur* are in many respects fitted for this purpose. The whole of the varieties are equally free-blooming and hardy, but the white and crimson shades of the flowers are the most useful. In a cut state they last a long time. I sow in the beginning of April and give the plants plenty of room for development.

Eschscholtzia crocea is another excellent annual for producing material for cutting from. Cut at the proper stage of development the buds have all the appearance of a deep-coloured Tea

Rose. In the bud state they last a long time cut. It is a continuous and free bloomer, and in our case sows itself. Now and again plants stand over the winter. The new variety Messrs. Carter & Co. distributed is a good companion to the

normal species. Either the seed had not been carefully selected or the "Mandarin" is not yet fixed in a variety, for in our case quite 50 per cent. of the produce of the seed packet proved the old crocea. Whether *Eschscholtzia* Mandarin

Fig. 57.—*ESCHSCHOLTZIA CROCEA FLORE-PLENO*.

will prove as useful to gardeners as its parent is somewhat problematical.—R. P. BROTHERSTON.

[For affording cut flowers especially, and for garden decoration generally, the new double *Eschscholtzia crocea flore-pleno* raised by Messrs. James Carter & Co. merits notice. It is very distinct, the flowers being of good substance and reddish orange in colour. The accompanying engraving is a truthful representation of the flowers as exhibited before the Floral

Committee of the Royal Horticultural Society, who granted a first-class certificate to this variety last year.—EDS.]

GENOTHERAS

THE Evening Primroses are a showy if not very refined class of plants, and they enjoy much popularity on account of the great size of their flowers and from these appearing in their

greatest perfection only after sunset. Why they are so constituted as to prefer blooming during the night, is a curious speculation. We have many examples of flowers which open only in sunshine, and also of others, as *Anagallis*, *Oxalis*, &c.,

which are so sensitive to barometric changes that they will close their petals hours before rain, but the *Enotheras* stand almost unique among hardy plants by their opening fully only during the night. One explanation appears to be, that from

Fig. 58.—*ENOThERA MACROCARPA*.

the construction of the pistil they do not require insect aid to fertilisation, the four arms of the cruciform stigma each touching one or more of the anthers. An exception in the case of the annual species *Æ. bistorta* seems to confirm this view. In

it the stigma is simple and not four-armed as in the most of the other species, and the style is much longer than the stamens; hence insect agency is required for fertilisation. Accordingly we find the flowers of this species remain open during the day,

the petals have more substance to enable them to withstand the sun, and bees call regularly there, while they pass unheeded the half-closed flowers of the night-blooming sorts.

(*Oenothera macrocarpa* is one of the best decumbent species. The flowers are a light yellow, very large, often 4 to 6 inches in diameter, and are produced in greater or less profusion from June to the end of September. It prefers a light rich loam, and if a little peaty so much the better. On heavy clay soils the plants are not long-lived, becoming annually weaker and often going off during the winter altogether. In such places it is best treated as an annual or biennial, sowing a pinch of seed on a slight hotbed in March and planting out in May. Many of the plants so raised will bloom moderately the same season and well the next. In light soil, where there is no need for this, we find that layering is the handiest mode of propagation. This should be done about midsummer, and the plants when rooted taken off early in autumn and wintered in a nursery bed. It is an admirable plant for rockwork, and when planted there should be allowed ample room so that it may not overgrow its less robust neighbours. It is a native of North America, and is sometimes known as *O. missouriensis*.—R. D. TAYLOR.

GROWING GRAPES IN COOL HOUSES.

WHEN I referred to this matter in your pages some weeks ago several of your correspondents, including Mr. D. Thomson, Drumlanrig, advanced some remarks on the subject mostly against what I said: yet I cannot help again saying that good Grapes may be very generally cultivated in unheated houses. I could send creditable Grapes if needed for the Editors' inspection cut from Vines that have never had the slightest fire heat applied to them since they were propagated. From my success here I should have no hesitation in planting an unheated house with Vines in the coldest district in the country, and I am anxious that any with a house of the kind will give the plan which I advocate a trial. The Black Hamburg is the best of all black Grapes for the purpose, and now is a good time for the preparation of a border and to have all in readiness for planting in spring.

Where plenty of good loam can be had add little manure; but where the soil is bad add plenty of the best manure obtainable. Start the Vines into growth from the very first in the house in which they are to grow, and as early in the season as circumstances permit. Most Vines will start naturally into growth by the end of March, and the following six months give ample time to thoroughly mature the crop, provided the Vines are treated like Vines under fire heat—that is, in closing the house with sun heat, keeping it shut altogether in dull days, and taking every advantage of sunshine and mild weather to promote development. Those who pay attention to these simple details may have Grapes as fine as if they employed fire heat, and of course with a very great difference in the cost of production.—A KITCHEN GARDENER.

ROSES AND ROSES.

To a certain extent I agree with Mr. Beachey in his pleasant and suggestive paper of October 31st that our election lists are not altogether guides for the general public, but I am hardly prepared to admit that for one exhibitor there are ten thousand who grow Roses. Our National Rose Society would be glad to be able to rely on ten hundred. I incline to think that as soon as people begin to grow Roses will these get to be like some of our great armies, spoiling for a fight. The owner begins to think he will make others own their excellence. A more general election we certainly need. As Mr. Beachey remarks, it is marvellous that Princess Mary of Cambridge is not named in the present one. I blush to find she is not in my own forty-eight, but her kinswoman Marguerite de St. Amand achieved twenty-three.

I rejoice to see what Mr. Peach says so truly of old "Glory," though I must confess I should couple with them for general excellence Cheshunt Hybrid. A really climbing red Rose still remains a desideratum. I only know of one with any substance, of course a Tea, which is Gloire de Bordeaux; next to it, perhaps, but at a long interval, comes Glory of Waltham, but you can hardly call it rampant, which Cheshunt Hybrid can easily be made. I do not understand its being left out altogether. No doubt it can hardly hope for a place in a forty-eight, but I have certainly seen it looking well in a seventy-two. And in a box of twelve Teas? Why, the help is enormous if only it can be persuaded not to develop too maternally.

What is more maidenly than its beautiful blushing bud? I heard two rosarians the other day talking of a close contest between two almost equally excellent boxes of twelve Teas. What was it decided it? Why, they said, colour. The box won, and deservedly, which possessed a Cheshunt Hybrid. It is also a good garden Rose from its fulness of bloom, in this respect an excellent contrast to some which Mr. Beachey mentions. Really some of our fat Roses seem to act as if they have done wonders in vouchsafing two or three blooms in a season. They are so slow in opening, and when at last they do it so alone in their glory, that I am always reminded of the "One, but a lion!"—the dignified reply of a lioness when a rabbit dared to chaff her on her very limited progeny. But I would plead for Mons. Boncenne in Mr. Beachey's list as a bad opener, that in my experience on a light soil it is always sure and fine. Duc de Wellington, also, though not robust, I should not speak of as a bad grower. Madame Berard I consider the best of all the seedlings of Gloire de Dijon. It is almost time the Hybrid Teas, as Mr. Peach says, had a class to themselves, and they might well do so under the patronage of that excellent patriarch old "Glory."—A. C.

CHAPTERS ON INSECTS FOR GARDENERS.

No. 23.

A REVEREND naturalist, referring to the difficulty there is in distinguishing from each other many of the species amongst the smaller moths, remarks that the practised entomologist is in the same position as is the shepherd who, running his eye over scores of individuals in his flock, notices something peculiar about each, although to a stranger the sheep may look exactly alike. That may be, and it is wonderful how the eye may be trained to notice minute differences; the cases, however, are not exactly parallel, for in the instance of the sheep they get to know their shepherd, but the moths don't recognise the entomologist! Then again, there is something "awfully" puzzling in finding that certain species (in the group of the Tortrices or "Button" moths especially) are so apt to vary that there may be as many as twenty or even thirty forms belonging to the same species, the variations being in the marking or colouring of the perfect insect. Extensive breeding of the species in question, carried on in different localities, is doing a good deal towards the clearing-up of sundry points that perplex the entomologist. Were our horticulturists as a body to take careful note of the times of appearance and the habits of the numerous species that in this and other orders are frequently brought under their observation, they would not only facilitate the adoption of measures for the checking of noxious insects, but help on the progress of natural science. The group of the Pyralidina, which in the Lepidopterous order follows the fat-bodied species known as Noctuidina that were last noticed in this series, includes species that are all of small size, yet of very different appearance. In this respect they agree, that the fore wings are longer than the hind wings and triangular; the larvæ are usually sixteen-footed, slightly hairy, slender, and very agile. Several of the species feed on plants under cultivation, but one or two only can be said to be injurious. Some species are, indeed, very common, such as the Small Magpie (*Botys urticalis*): these, however, chiefly feed on various wild plants, and the moths enter gardens either for shelter or from their partiality to sweets. The Deltoids or Smuts (*Hypenæ*) are placed first, the family not containing many species; but in some seasons the insects swarm in grassy places. Their appellations have arisen from the fact that when the moths are reposing the wings are folded into the form of the delta or triangle; the head is also furnished with remarkably long palpi. In the family of the Pyrales we find some handsome species, and some that have a remarkable history. Here are classed two species whose destructive habits are undeniable, though not affecting gardeners, at least not in their particular calling. The three species called "Meal Moths," the most abundant of which is *Pyralis farinalis*, have glossy and elegantly marked wings, but this will be admitted by few as any extenuation of the injury the larvæ cause to meal or flour. Mr. Wood asks pertinently, "What could they have fed upon before men took to grinding corn?" Then *Aglossa pinguinalis*, known also by the odd name of "Tabby" and a pretty species, is on the watch during its season to deposit its eggs on greasy clothing, having a partiality for horse rugs that renders it an object of dislike to grooms. The caterpillar is almost as wiry as the wireworm, making for itself with ease comfortable grooves, in which it revels on the material.

Few of the larvæ of the Pyrales totally hide themselves from view, though some feed in leaves slightly drawn together. Often they have a transparent or glassy appearance, as has that excessively common larva of *B. sambucalis*, which strips the Nettles in company with *B. urticae*. The moths generally sit by day on palings or trunks of trees, escaping detection by their attitude or colour; some, however, fly during the day in an undulating manner. A notable insect—referred to by sundry authors, some of whom put it in this group, while others think that it belongs to the Tortricina—is that enemy of the Vine designated the Vine Pyralis, or more correctly *Enectra pilleriana*. Fortunately for us it is a species of extreme rarity in most parts of Britain, and, according to Mr. Stainton, its sole food as yet observed is the seeds of *Iris foetidissima*; but in France it has a history attaching to that of the Vine which reaches back to the sixteenth century, when in 1562 “prayers, processions, and exorcisms” were tried to check the ravages of the creature. If we are to believe the old chroniclers it first showed itself in the vicinity of Paris; even as recently as the years 1836–38 the pest was terribly abundant in many departments; now probably for some time the Phylloxera is destined to supplant it, such revolutions amongst insects being not unusual. On the whole I suppose the Phylloxera from its sly habits might be adjudged to be the worse foe, but modern science suggests methods of dealing with these enemies concerning which our ancestors were quite in the dark. The French have, however, long been alive to the fact that the Vine Pyralis is best nipped in the bud—that is, destroyed in the egg state, the leaves laden with these being hunted up and burned or buried deeply. According to Figuier the loss through this insect (mainly) in the two departments of the Saône-et-Loire and the Rhone during 1837 alone amounted to three millions and a half of francs.

The habits of this foe of the Vine are somewhat peculiar. Some time in July the moths—the wings of which expand about three-quarters of an inch, and which have palpi thrice the length of the head—are noticed flying over the Vines, laying eggs in little clusters that are fortunately rather conspicuous. Hatching in August the young caterpillars are little inclined to revel in the foliage that is then abundant, but in the course of a few weeks they hibernate in cracks and crannies in or near the Vines; re-appearing in spring they attack the young leaves and the just-expanding flowers at a most critical time, binding these in masses, within which they are themselves concealed. “Desperate diseases require desperate remedies” says the proverb, and very probably the comparative immunity that the vineyards now enjoy is due to a proceeding advised by M. Andorim about thirty years ago. On his recommendation the proprietors carried out an extensive destruction of the Vine props and the shoots in which the caterpillars had harboured.

The “China-Marks” are a singular family amongst the Pyrales, taking their name from a fanciful resemblance between the markings upon their wings and those upon choice porcelain. Each of the caterpillars of the four British species leads an aquatic or semi-aquatic life; the typical species, *Hydrocampa stagnalis*, subsists upon the common Duckweed, constructing therefrom a kind of case, or from the leaves of a *Potamogeton*. These caterpillars can live entirely under water, or partly within it, when plunging beneath its surface they carry down with them a bubble of air. Most of the *Hydrocampa* have gills like filaments by which they breathe. One species actually passes its chrysalis stage amongst submerged leaves, and how the delicately winged moth in coming out escapes drowning remains somewhat a mystery. Passing by the group of the Pearls—to one example of which allusion has been made, the moths of which have lustrous wings, in some instances dark, in others pale—we arrive at the large family of the Veneers (*Crambina*). Stray specimens belonging to the *Crambina* enter gardens, but the majority are to be found in fields, on grassy banks, and amongst Reeds or Sedges. Individuals of the Gigantic Veneer (*Schoenobius gigantellus*) are occasionally taken measuring 2 inches across the wings; ordinarily they would be half an inch less, but most of the Veneers do not exceed the inch. From the manner in which the wings fold over the thorax the pinning-out of specimens gives the collector some trouble, as well as the subsequent naming. Some species, indeed, are easily recognised, like the Wainscot Veneer (*Chilo pragmatellus*), after which the enthusiast has often rushed deep into the mire of sedgy islets, but the majority are puzzling to make out, nor are they, from the habits of the larvæ, frequently detected in their earlier stages.

The Honeycomb Moth (*Galleria cerella*) is a *Crambus* with

propensities that make it much disliked by bee-keepers. It appears to attack both bee hives and the nests of wild bees, and in hives the larvæ not only damage the comb, but by pressure they cause the death of a number of young bees. The food sought by this insect is the wax, not the honey, and in order to protect themselves from the possible attacks of the bees, the larvæ form long silken galleries within which they reside, only thrusting out the horny head and the front segments when they feed. In some cases it is evident the moth cannot escape but must die in the hive, and this probably assists in keeping down their numbers. The less common moths (*Melia sociella* and *Achroia grisella*) are also wax-eaters with similar habits.—J. R. S. C.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Laying Down Broccoli.—Spring Broccoli in some soils is apt to become very luxuriant, and from the succulent character of the growth to be more susceptible of injury by frost than that grown thinly in comparatively poor soil. It is a capital practice, when the growths are luxuriant and the plants long in the stem, to lay them with the heads towards the north. The soil is taken out with a spade on the north side of the plant, deepest near the stem and shallowing outward, so as to admit the stem of the plant being covered-up to the head. The spade is then inserted to the south of the plant and 9 inches or so from it, and the plant is laid in the trench and covered with soil obtained by making the opening for the next plant. In covering the stems the soil should be trodden rather firmly. The operation of laying the plants checks their growth, and the stems being buried the plants are in a condition to withstand the rigour of a severe winter; indeed we have often known those so treated escape injury, whilst those having the stems exposed have been seriously damaged. That very desirable autumn Broccoli, Veitch's Self-protecting, is now turning-in, and though it is harder than Snow's and any of the Cauliflowers, it yet is desirable to break a few leaves over the heads so as to make all safe. When the heads are about the size of a breakfast cup the plants may be lifted and placed in frames or pits in moist soil, where the heads will keep in good condition for a long time.

Autumn-sown Onions, Lettuces, &c., and that valuable crop Winter Spinach, are often allowed to stand so thick upon the ground, and also to be encumbered with weeds, as by depriving the plants of light and air to induce a tender weakened growth succumbing to frosts, which plants properly thinned and kept free of weeds withstand with comparatively little or no injury. When the plants are kept thin their growth is solidified and in the best condition for resisting wet and cold. See that the plants are not too thick and their growth not retarded by weeds and fallen leaves, but keep them clean, and healthy crops will follow.

FLOWER GARDEN.

Falling leaves will keep the broom in constant use for some time yet; although it is hardly to be expected that grounds in the immediate vicinity of deciduous trees can be kept in good order, yet those in charge will need to be ever on the alert to detect anything that detracts in any way from the neatness that should prevail in all gardens. Lawns can scarcely have the roller passed over them too often, which, besides improving the texture of the grass, is a quicker and better way of removing wormcasts than sweeping. Some lawns may yet require to have the machine passed over them, as the grass by growing irregularly presents an untidy appearance. Weeds, such as Plantains, Daisies, &c., should be removed, detracting as they do from the rich velvety appearance of the lawn, the pride of English pleasure grounds. Walks, too, must be well swept and rolled, as by such means only can they be made comfortable; those having the surface loose admitting wet are more readily acted upon by frost, rendering them unsightly and disagreeable.

Where it is intended to make new beds or borders of Roses those about to plant should, with a view to securing good plants, give their orders at once, as the earliest planters generally have the pick. Nurserymen, like other traders, wishful to supply a good article, do so upon the principle of supplying the best first, best last, and consequently best always. The soil should be trenched, a liberal dressing of manure being given and mixed with the soil beneath with a fork, and another good dressing given at the surface, which should be forked-in. This is [all that good] loams require. Soils naturally stiff suit Roses on the Briar, light soils inducing suckers, which enfeeble the plants; on such soils the Manetti stock should be employed, and if the cuttings have been properly made there will be no growth from the stocks. Manetti roots do not produce true suckers, but if eyes are left in the stocks these will grow much too freely. If small lumps of clay can be mixed with light soil the application will be highly beneficial. Soils not only light but shallow will be improved by being liberally mulched with manure. Some Roses do well on their own roots, especially in light soil, but they are best worked. In planting those on the Manetti they should be planted so that the jun-

tion of stock and scion is buried beneath the soil about 3 inches. After planting mulch with litter, but defer pruning until spring.

FRUIT HOUSES.

Figs.—The trees in pots for affording fruit at the close of April or early in May will now need to have the wood dressed over with a brush, using soft soap (1 lb. to a gallon of water, brought to the consistency of cream by adding flowers of sulphur), being careful when using the mixture not to rub off the young fruit, the shoots of the current year requiring to be carefully handled. Very little pruning will be required, the trees having been regularly pinched or stopped during the growing season, but if the growths are too crowded or irregular they may be thinned or cut-in so as to render the trees symmetrical in shape. The woodwork and the walls of the house should be washed with scalding water and then done over with quicklime and sulphur. As a mild bottom heat is essential to a successful swelling and perfecting of the earliest crop, the pots should be raised upon loose bricks in the position they are to occupy, and the pits be filled with Oak or Beech leaves and pressed firmly. If the pit be no more than about 2 feet to 2½ feet in depth a third of stable litter may be added. Care must be taken in that case to avoid overheating, not allowing the heat about the pots to exceed 65° until growth takes place. The house may be kept close and moist by sprinkling twice or thrice a day in bright weather, employing fire heat to maintain a temperature of 50° at night, 55° by day, and with sun heat 60° to 65°. If the soil in the pots be at all dry a thorough soaking of water must be given.

Trees permanently planted out in borders intended for early forcing should now be untied from the trellis and pruned. Those with the roots restricted to small borders will require little more than thinning out the shoots where too crowded, but those not having the roots restricted will require a hard pruning at the upper part of the trellis, cutting back those shoots that have attained to the limit of the trellis to where the succeeding shoots start, in order that they may occupy their place in the ensuing season. Thin-out, removing entirely any elongated spurs, reserving such as are short-jointed and fruitful. The house should then be thoroughly cleaned as before advised, and the trees also dressed. The trees should then be secured to the trellis, allowing room for the growth of the branches, forking over the surface of the border slightly, removing the loose material, and apply a top-dressing of short partially decayed manure about 3 inches thick, giving a good watering. Ventilate fully at all times, except when frost prevails, which it is well to exclude. Succession houses should be pruned and cleaned without delay, especially where insects have obtained a footing. Complete any root-pruning, lifting, &c., remembering that Figs with the roots restricted or confined to limited space are more manageable and fruitful than those with an unlimited root area. Any unfruitful trees should be severely root-pruned, and the roots restricted to moderate-sized borders, depending more upon active feeders near the surface encouraged by mulching than a large extension of roots.

Peaches and Nectarines.—If ripe fruit is required in late April or early in May forcing may now be commenced. If the crop is taken from trees in pots they should be placed in a light airy house, and a good watering should be given unless the soil is in a thoroughly moist condition. If the earliest crop is taken from trees planted out a thorough watering should be given the inside borders, and if the trees are weakly a soaking of liquid manure not too strong will tend to a more vigorous break. The house may be kept close and the trees sprinkled overhead in the morning and afternoon of bright days, admitting air abundantly whenever the weather is bright, and employing no fire heat only to exclude frost, for the slower the trees are excited the stronger will be the blossom. The outside border must be well protected with litter, and if tarpauling is put on the top it will be useful in preventing the soil from becoming chilled by snow and excessive rains.

All the trees in the succession houses will now be bare of leaves except in the case of a few late varieties, which should not be removed until they part readily from the shoots; but when they are all off, or brush off easily with the hand or a broom, undo the trees from the trellis, prune them, thoroughly clean the house, and if need be paint the woodwork and trellis, dressing the trees, and tie them to the trellis, leaving room for the branches to swell, tight tying being prolific of gum. Remove the surface soil and replace with fresh, and give a good watering to the inside borders, thereby having all in readiness for a start when required. Any lifting, root-pruning, or the introducing of fresh trees should be performed forthwith, the planting of houses now proceeded with or so soon as the leaves are nearly off the trees to be removed. Trees for planting in houses are best three to five years trained and prepared for lifting by digging round them a year previously. Such trees lift with an abundance of fibres; and being carefully planted they force very well indeed the first season, not being brought on too rapidly, and a moderate crop taken. It is always best to select such trees in preference to planting young ones, which do not fruit much the first three or four years; hence the advantage of planting trees in an already bearing state.

Orchard House.—Complete the top-dressing of all fruit trees in pots. A good watering should be given where the soil has be-

come at all dry, after which the pots should be well covered up with litter in a dry state. It is a mistake not to dress the trees so soon as the leaves have fallen; at least give them a good syringing with quassia water, 4 ozs. to a gallon of water, boiled for fifteen minutes, then straining and adding 4 ozs. of soft soap; but it is preferable to dress the branches with 1 lb. of soft soap dissolved in a gallon of water, adding tobacco powder to bring it to the consistency of thin paint, or tobacco juice may be added in the proportion of half the soapy solution, applying it to the trees with a brush, taking care not to dislocate the buds. The soil of borders in which trees are growing must not be allowed to become too dry. The top-dressing or root-pruning being completed a good watering should be given and the surface mulched with partially decayed manure. Unless the weather be frosty the ventilators may yet remain open day and night, closing, however, in severe weather. Fig trees in pots placed in some other structure to finish ripening the second crop of fruit should, so soon as that is completed, be surface-dressed and returned to this structure.

PLANT HOUSES.

Orchids.—With the gradual lowering of the temperature such plants as *Aërides*, *Vandas*, *Phalænopsis*, *Saccolabiums*, and similar kinds, will have been brought into a partial state of rest, consequently only sufficient water should be given at the roots to keep the moss damp, for if allowed to become too dry the bottom leaves will suffer and fall off. Premature growth should be prevented by keeping the house comparatively dry and cool. A little water should be poured over the paths on fine mornings to create a moist atmosphere. Very little air will be required, except to keep down the temperature. Dendrobiums for the most part will now be at rest, and must be kept cool and dry. Cattleyas require to be kept rather dry, but the growths must not be allowed to shrivel. Very little water will be necessary to keep them plump. *Lælia purpurata* not having completed its growth should be placed at the warmest end of the house in plenty of light. *Cypripediums* require liberal supplies of water at all seasons, requiring no rest. *Lycaste Skinneri*, though a water-loving plant, requires less at this season, but the roots must not be allowed to become too dry, or the pseudo-bulbs will shrivel. The plants should be well elevated in the pots so as to allow the water to pass away freely, or the flower buds decay when only an inch or so long. *Calanthe vestita* will not require much water after the plants commence flowering. They should have plenty of light and a dry atmosphere, too much atmospheric moisture and insufficient light causing the buds to drop and the flowers to spot. Many *Odontoglossums* and *Masdevallias* will be growing freely, and must be kept moist at the roots. Care must be taken at this season not to produce a very moist atmosphere. *Odontoglossums Alexandræ* and *Pescatorei*, with others of the same type, are growing vigorously, and require a good supply of water, damping overhead on fine mornings with a syringe or fine-rose watering pot, using tepid water for the purpose. Plants in flower may be removed to a drier atmosphere. *Anæctochilus* will now require great care. A little air must be left on the frames or bell-glasses, and the glasses be cleared every morning. Very little water will be required for two or three months, only sufficient to keep the sphagnum moist. A strict look-out must be kept for slugs at night.

TRADE CATALOGUES RECEIVED.

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

PLAN OF ROSE GARDEN (Subscriber).—We do not furnish plans, but are always ready to advise on those submitted to us and also on the planting of the beds. We shall, however, shortly publish a plan of a Rose garden that may be of use to you in common with other readers.

BIRDS PECKING FRUIT (M. A.).—Various birds are addicted to this practice, and the common tom tit is a frequent offender, pecking, as if for mischief rather than food, many fruits near the stalk. You can only determine what particular bird is the delinquent in your garden by close observation. Possibly we have named the culprit—watch him.

FRUIT TREES FOR WALLS (Smetheick).—The selection of varieties to which you refer is a good one for your district. You will find reliable in-

formation on selections of fruit for various aspects on page 283 of the Journal of October 10th, which also contains a more complete selection than the one you have named. The same number gives information on the right distances for planting various wall trees.

GATHERING MEDLARS (*An Old Subscriber*).—They ought to be gathered in November when the leaves commence falling from the trees. They should then be spread singly in a dry room, stalk side upwards, until incipient decay commences, or until they are what is termed "blotted," when they are ready for use.

GROWING ANEMONES AND RANUNCULUSES IN POTS (*F. G. O.*).—They do not succeed well in pots, but are sometimes so grown, using rich loam, inserting the tubers 2 inches deep, five of Ranunculuses in a 6-inch pot and three or four of Anemones in the same size of pot. They should then be plunged in ashes in a cold frame, not watering them until growth takes place, then give supplies proportionate to the growth of the plants. They will require air freely in mild weather, removing them to a greenhouse or sunny window when showing for bloom, then watering them copiously.

GREENHOUSE (*Idem*).—Nothing whatever will thrive in a house as high at times as 100° to 120° by fire heat. The furnace must be altered—that is, made larger, so as to admit of a larger fire and to secure a more moderate heat, regulated by a damper. With a temperature of 45° to 50° by artificial means you may hope to succeed with all the plants you name, the Carnations being of the tree kinds. The Roses would have been better had they been established in pots a year before forcing, though they will succeed if carefully lifted and not brought forward too rapidly.

CLIMBERS IN COLD GREENHOUSE (*A Young Beginner*).—The Clematis and Passion-flower will not suffer from frost, but it is possible, if the winter be severe, that the Plumbago would be more or less injured, though it is probable it might not if kept dry at the roots. You may cut them all down to near the base of the plants in spring, but not to the ground, as it is likely they are old and have no dormant eyes at or beneath the surface of the soil. There is no need to cut them down on account of mealy bug, as it is destroyed by syringing—a wineglass of paraffin to four gallons of water, thoroughly mixed by filling the syringe and squirting a few times sharply into the vessel and then upon the plants, every second squirt being into the vessel, which is necessary to keep the paraffin well mixed with the water, without which the syringing loses its efficacy. A thorough cleaning and painting of the house would be a means of subduing the bug. Keep the Rose cuttings in the pot in the cold frame through the winter plunged in ashes to the rim of the pots, which will be a better place than a room window. They will root provided the wood was ripe.

DISTANCE OF SHELVES IN FRUIT ROOM (*F. J.*).—They may be so close as to admit of the fruit being readily examined, which to some extent is determined by the width. Twelve inches will answer for shelves not more than 3 feet wide, adding 6 inches for every increased foot of width. Pears which succeed against an east wall:—Jargonelle, Beurré d'Amanlis, Beurré Superfin, Durondeau, Conseiller de Cour, Doyenne du Comice, Marie Louise, Beurré Diel, Beurré Bachelier, Glou Morceau, Joséphine de Malines, and Bergamotte Esperen. Most Apples succeed well as espaliers. *Dessert*: King of the Pippins, Cox's Orange Pippin, Dutch Mignonne, and Reinette de Canada. *Kitchen*: Worcester Pearmain, Cox's Pomona, Cellini, and Dumelow's Seedling. It is preferable to purchase trees at three years old, two years trained, than maiden trees at a third of the price, as the former sooner come into bearing; but where ground is not begrudged, remaining unprofitable, the maidens suggest themselves as most economical.

TEBBS'S UNIVERSAL STOVE (*Bingley*).—The address is 98, Chapside, E.C.

GARDEN DIARY (*W. S.*).—Write to Mr. Richard Nisbet, Aswarby Hall, Fellingham.

EUCALYPTUS GLOBULUS (*E. T.*).—The Eucalyptus will do perfectly well in any good garden soil, and is only hardly in extremely favourable situations. It will also do very well in a well-lighted hall where there is a coke stove, provided the fumes of the coke do not escape into the apartment.

NAME OF TREE (*E. M.*).—Taxodium sempervirens.

NAME OF SEED (*E. B., Normanton*).—The seed appears to be of a variety of Lupin, but which variety it is impossible to determine.

NAMES OF FRUITS (*F. McLennan*).—1, Gansel's Bergamot; 2, probably Crassane, but a very indifferent specimen; 3, Zephirin Grégoire; 4, not known. Apple, Golden Pippin. (*C. H.*).—Apples: 1, Norfolk Beefing; 2, Flanders Pippin; 3, Winter Greening; 4, Reinette de Canada. Pears: 1, Beurré d'Arenberg; 2, probably Beurré Rance. The specimens of Hawthorn are by far the finest we have ever seen. (*John M. Miller*).—It is Cornish Gilliflower certainly. (*L. W.*).—They are poor specimens, but sufficient to enable us to say that both are Black Hamburg. (*F. Wood*).—1, Northern Greening; 2, Not certain; 3, London Pippin; 4, No doubt Minshall Crab. The Pear is certainly not Doyenne du Comice, but one of those valueless autumn Pears of which there are so many. You had better graft it. (*N. S. R.*).—1, Beauty of Kent; 2, Alfriston. (*R. R. Woolton*).—1, Gloria Mundi; 2, Beauty of Kent; 3, Alfriston; 4, Federal Pearmain; 5, Soldat Esperen; 6, Beurré d'Arenberg. (*H. H.*).—1, Hunthouse; 2, Wyken Pippin; 3, Winter Greening. (*P. M.*).—Not known.

NAMES OF PLANTS (*Cheshire Reader*).—1, Cytisium falcatum; 2, Asplenium, species not determinable; 3, Eonymus japonicus aureo-variegatus; 4, Sedum aizoidium variegatum; 5, Sedum aizoidium. (*E. S. W.*).—The Orchid is without doubt Maxillaria picta.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

THE MANAGEMENT OF YOUNG CATTLE.

(Continued from page 355.)

HAVING followed up the question of feeding young cattle for early maturity as beef, whether fed on pasture land in part or entirely under cover upon the produce of the arable land combined with artificial food, we must look to the requirements of the home farm and its proprietor. In very many instances a considerable

portion of the cattle as well as dairy produce is required at the establishment or mansion in connection with it, and the articles of consumption, whether of beef, mutton, pork, or dairy produce, must be of the best, and of course small joints of the highest quality of meat are indispensable. Let us first consider the beef furnished by young cattle, and take the Shorthorned breed, which at full age is one of our largest and heaviest varieties of cattle. When young steers and heifers can be fed up to full condition for slaughter at from twenty to twenty-four months old they furnish meat in moderate-sized joints of admirable quality. Whether, however, the animals are Devons, Herefords, Sussex, or Shorthorns, when properly fed upon the method advised in the former part of this paper they are each adapted for the purpose; but in case older meat of the fuller flavour is required, instead of breeding the animals we should prefer to buy cattle of four years old, either of the Galloway, Scot, Aberdeen, or North Devon breeds. Either of these will furnish the nobleman's table or that of the greatest epicure with meat of the finest quality and highest flavour, but they will be purchased from districts differently managed and stocked compared with the home farm under profitable management.

The rearing and feeding, together with the general management of young cattle intended for the dairy, up to the time of producing their first calf upon the home farm, must now engage our attention. In our paper written for this Journal on the 23rd of May last we stated the method of management up to the time when they reached the age of one year. Our object is now to continue the subject of management as heifers intended for the dairy, whether of the Shorthorned, Ayrshire, Alderney, or Kerry breed, because correct management for the one must be also good for the other if we only consider all the points connected with their general health and condition and the period of the yearning their first calf. Each of these subjects is of the utmost consequence and importance connected with home-farm management. We do not on this occasion propose to refer to the relative merits of the different breeds of cattle as before named, for we hope to find an opportunity at a future time to compare the merits of them as dairy cattle. We therefore proceed to state for our purpose that the heifers should come one year old in the month of February, and we will suppose that they will be required to be accommodated in sheds and yards as they have been from the month of October previous until the first week in May, when they will be required to go into the park or pasture for grass feeding. Between the period of February and May they may be accommodated with a shed and yard in divisions upon the same plan as before stated for the young steers, and more particularly will it be requisite in the case of the animals being of different breeds. In promiscuous mixture of Shorthorns, Alderneys, Kerrys, &c., the large animals are sure to tyrannise over the smaller weaker stock and monopolise the food, obtaining the lion's share. It is therefore desirable that the heifers should be kept in twos or threes in separate divisions of the yard and shed, not only that they may feed more comfortably and with more regularity, so essential to their health, but to prevent accidents by the stronger injuring in various ways the weaker animals. We do not propose that the heifers should be confined entirely to the sheds and yards during the spring, but we think it best that they should have air and exercise and access to water in a paddock near the home farm premises for two or three hours during the day. Grass feeding we always like to hold in reserve until it furnishes a good bite, as it usually does the first week in May. This appears the most natural mode of rearing heifers; but we recollect for some years, where we were peculiarly situated as to pasture upon a home farm under our care and management, that we kept our heifers entirely in yards and sheds as described both in winter and summer, and until after they had yeanned their first calf, although when turned out to graze it was days sometimes before they attempted it, desiring only to return to their previous quarters and mode of life; and although we cannot recommend it as a plan for general adoption, yet we are compelled to say that we had as fine dairy cows as we have ever seen reared in this

way. We never recollect having ill health or accident overtake them whilst confined to the yard and shed; the principal objects in view were the feeding the animals entirely upon the produce of arable land, and the treading a large quantity of straw into manure, which was allowed to accumulate under the animals.

The mode of feeding in the yards, &c., should be a moderate allowance of decorticated cotton cake, say 2 lbs. per day each, with not exceeding 30 lbs. of mangold or Swedes per day, the cake being given in a fine or meal state mixed with the roots. Sweet straw or inferior hay *ad libitum*. The hay should not be mouldy, but may be the produce of inferior pastures. It is therefore a question of convenience which fodder should be used, seeing that straw and such hay are about the same in money and feeding value. Upon this combination of food the heifers ought to be, in the absence of disease, in blooming condition when they leave the yards and enter upon grass feeding. It will depend upon the quality of the herbage in the pastures whether they should continue to receive the 2 lbs. per day of cotton cake, for unless the grass land should be very poor the cake may be dispensed with until they leave the pastures and enter upon yard and shed feeding in the succeeding winter.

The next point to be considered is the lying of the pastures, because if it is low moist meadow land, and below the fog level, the animals should be removed to higher ground, either pasture or old lea, upon the arable land at night time. This matter is of especial importance in securing the health of the animals and freedom from blackleg or quarter-ill; other ailments are soon discovered and easily treated. The best and highest conditioned animals of any breed being most disposed to quarter-ill, it is advisable to bleed them from the neck vein, and take about a quart of blood from them about midsummer, so as to ascertain whether the blood is unusually defibrinated, if the animals have not previously been setoned in the brisket or dewlap. [See the article upon the quarter-ill in this Journal, new series, vol. xxxiv., page 418.]

The next question is as to the best time of the year for the heifers to bring their first calf. We recommend the month of May for that purpose; therefore, a well-bred yearling bull should be allowed to run with them from the 1st of August until they have all been served. The bull should then be removed, and they will then drop their calves at about twenty-seven months old. We recommend this age as being the best period for bringing out dairy stock, and as being the best calculated to insure their milking capacity. Sometimes heifers are allowed to go on to three years of age before yearning their first calf. This is advisable only in the case of stock intended for exhibition, so that the stock may arrive at greater size and perfection as show animals. We have no doubt from our own experience that heifers which drop their first calf at from twenty-four to twenty-seven months old will not only make the best dairy cows but the most regular breeders and less subject to barrenness. It is further advisable that heifers should suckle their calves up to a good age, say ten or more weeks, and then have other calves in succession put to them for the whole milking period, which it is calculated to extend and prolong. This will be most beneficial to them as milch cows ever after, seeing that the calves are better milkers than the milker or dairyman. It is also extremely desirable that the pastures whereon the heifers are grazed should be well fenced, otherwise when young stock are allowed to break their bounds they may become riggers in the future, which scarcely any fence will stop. It being also likely to cause abortion and other serious damage to them, it is recommended that they should have only pure water for drinking, either from a running stream or a well-supplied pond of pure water. Such as we often see on farms—ponds highly coloured with the drainage from the farm yard—is a fruitful source of blood-poisoning. It is, however, sometimes argued by farmers that the cattle like it best, but this can only be an acquired taste, for it is impossible to admit that it is best for them that their drink should be composed of diluted urine and other fæcal matters.

The pastures being always fed close care should be taken that the bunches of grass be cut before seeding, in order to prevent the formation of ergot in the seed heads, which is baneful to the breeding stock and likely to produce abortion. It is also requisite that particular attention should be paid to their removal to and from the pastures, yards, and sheds, so that no injury may occur to the animals in passing through gateways, &c., by hurried driving. If possible each kind of stock should be kept in separate herds, otherwise the stronger breeds, such as Shorthorns, will often seriously injure smaller stock like Alderneys, and when the stronger ill-use the weaker it often leads to abortion. Whatever may be the cause of abortion the stock should be watched with a vigilant eye, for when one case occurs it is sure to spread to other animals if the affected one is not instantly removed on the symptoms peculiar to abortion being first discovered.

When the period of summer grazing is well advanced, and the grass begins to become stale on the pastures, the heifers should have cabbages on the pastures. These, when large heads, have very strong and hard stumps, and sometimes these stumps when not split with a hook are apt to choke the young animals whilst endeavouring to masticate them. When the animals are removed

from the pastures to winter quarters they should be treated in the yards and sheds as in the previous winter, but no more than two should be allowed to feed in the same apartment. As the time of calving approaches they should be alone in a box or pen, and receive the attention required from the dairyman.

WORK ON THE HOME FARM.

Horse Labour must still be applied to the preparation of land for wheat, and seeding the same if not already completed; for although we recommended only a short time ago that it would be well to defer the seed time until the end of November or first week of December on account of the slugs being so very numerous upon the clover leas, we have, however, now a decided change of weather, and instead of genial south-west winds and growing atmosphere we have north winds, night frosts, and an atmosphere the reverse of growing, for the vegetating of plants, grass, or seed corn respectively. The sooner the wheat is all sown the better, for should the like weather prevail for some little time the wheat plant will be quite safe from the depredation of slugs. In those cases where the wheat land is all seeded, the work will now be finishing the autumn cultivation of land which was partially done before the wheat season. In those instances where the land might have been worked down, and the grass and weeds cleared away; yet since that has been done where there is couch left in the land, any small bunches will by this time have vegetated sufficiently to show their position, and may be easily forked out and carted away before the final or fallow ploughing. It is through the disregard of the little lumps of couch that the succession is kept up, causing immense and costly horse labour in the future, and which might have been prevented at small cost by judicious hand labour.

The feeding of horses at this time, now that green fodder is not available, should be regarded as important, for we certainly have no right to expect that the animals can be as healthy and as capable of severe labour when placed suddenly upon corn and dry fodder diet only. We again advise that some roots either of carrots or Swedes should be given in addition with corn and hay. Wheat is so low in price that it is now a valuable auxiliary in horse-feeding, one-third of wheat to two-thirds of oats, both being cracked or crushed before feeding—those cold samples which are disregarded by the miller, and if sold at all must be sold at a lower rate than any feeding stuff in the market, except, perhaps, maize, will be very useful.

Hand Labour is now required in completing the storage of root crops, both of mangold, carrots and Swedes, and where it can be obtained seaweed is the best of all coverings for roots in heap, requiring but little else either of straw, or earth. Upon the heavy-land farms the wheat land as well as all the fallows will require to be carefully water-furrowed. Some men will also be required to cut and make hedges and clear out ditches upon those farms where it is not customary to keep them closely trimmed in the summer months. All the horned cattle on the farm will now require dry fodder either of hay or sweet straw, as well as a moderate allowance of roots, except the fatting cattle. These will require straw only when fed with the usual quantities of cake, meal, and roots, which should be given without being cut into chaff, as ruminating animals require the long fodder to distend the stomach and enable them to digest the other kinds of food. Sheep, both store and breeding flocks, as well as those feeding for the butcher, will now require minute attention by the shepherd. The breeding ewes ought especially, to be kept as long as possible without eating roots. They should however, have a run upon the pastures where the grass is old, and some of this should always be reserved for them. When the grass becomes short, cabbages, either White-hearts or the Thousand-headed, are capital food for in-lamb ewes, but they should have them strewed over the pastures, or upon old lea grass in a very moderate quantity at a time, certainly not as much as they can eat. We object also to their having hay before lambing, as being injurious and likely to produce abortion. We prefer straw cut into chaff, and made damp to receive cotton cake in meal in admixture or otherwise; we have known molasses mixed with straw chaff do as well as any mixture to induce them to eat straw. The early lambing horned Dorset and Somerset ewes have now dropped two-thirds of their lambs, and will therefore require great care in their management, for the lambs never entirely recover a serious check, whether it arises from want of proper care in feeding or mismanagement of the ewes, as short supplies of milk lead to a check in the condition of the lambs. Foot rot, too, is often the cause of a serious check to both ewes and lambs unless properly treated.

THE CRYSTAL PALACE POULTRY SHOW.

THE great poultry "Derby" has once more come round like, and yet unlike, all its predecessors. We see the same faces year after year, the same pens—in fact, the same arrangement of classes, and yet there are every year special features which prevent any real sameness in the shows. Some particular class contains some special wonder, the year has been exceptionally good for one breed,

or some one exhibitor shines above others. Then there is new interest in every meeting. The general arrangement has been much upset this year by the great American Circus, which occupies the central transept, and practically through all the afternoon cuts the Palace into two parts. We were much vexed at the prospect of this, but must confess that the anticipation was worse than the reality. Of course the effect as a whole is not so good, still everything has been done to make the best of the circumstances. The poultry are in the western half of the building and stretch right to the end among the ferns and water, the Pigeons in the east extend into the tropical department.

Dorkings, of course, hold their old position. The Dark variety number ninety-five in four classes. The old cocks do not please us; long stilty legs seem in favour—a great change from the traditional Dorking type. First certainly is an immense bird, but he has these prevailing faults; second would be a good bird if 3 inches could be cut out of his legs; third seemed unaccountable; the bird has a comb entirely lopping over and very crooked toes. Very highly commended is a stout, short-legged, old-fashioned Dorking. The hen class is far better than that for cocks. First Mr. Parlett's beautiful old hen, which won the cup two years ago; we know no hen like her, and her comb looks as fresh as that of a pullet. Second short-legged; a large and true Dorking, moderately dark in colour. Third very fine too, lighter in colour. Fourth white in feet with crooked toes. Ireland produces the three first cockerels. The Messrs. Smyth show some fresh wonders. First is an enormous bird not over-good in comb. Second belongs to the same exhibitor; he is good in colour, comb, and form, but his feet are too dark. Third is leggy with a very bad comb, fourth stilty with swollen toes, fifth a young and very good bird. Among the rest we specially liked Mr. Taylor's very highly commended bird and Mr. Lingwood's unnoticed one; 39 (Caws), 41 (Lingwood), 49 (Peel), and 51 (Barker) are all good. Pullets are a nice class, in most respects better than the cockerels—but, oh! the first award! the most antique-looking pullet we ever saw; large indeed, but in the opinion of every Dorking judge we could find not a bird of 1878. When will judges cease to encourage the exhibition of such birds, which for their utter want of condition ought to be passed over? While we write it is still *sub judice* whether a protest shall be made or not. Second a good all-round bird. Third in nice condition, white in feet; we think we saw her at the Dairy Show. Fourth large, but a little rusty in colour, very white in feet. Fifth a bird rich in colour and bright in head, but with a sixth toe on one foot. Mr. Taylor's and Mr. Burnell's very highly commended both good. Silver-Greys.—First-and-cup in cocks is a noble short-legged Dorking. His neck hackle is hardly quite grown, when it is full he will be a very perfect bird. Second a fresh-looking cock; third very fair, white in lobes. In hens Mr. Burnell is again first with his splendid square hen; second also very large, not quite so good in feet; third small, but nice all round. In cockerels an upstanding round-breasted bird is first-and-cup, the son, we believe, of the cup cock; he, too, will look better in a fortnight with a fuller hackle. Second a good cockerel, wanting the breast of the cup bird; third fair, but weedy. The first pullet is not remarkable save for colour; second an old-fashioned bird very short on leg. We liked 139 (Burnell), highly commended. Cuckoos are stationary. First a well-shaped and dark pair, the cock, perhaps, a little rusty in colour; second dark again, the cock too dark in feet and bad in toes; third very pretty in comb and in good condition, the cock rather light in colour. White.—The cup for Cuckoos or White goes to the first White cock, we fancy the largest bird of the breed we have ever seen; he might be shorter on the leg. Second a very pretty very white cock; third well shaped and not very large. First in hens the fine old cup-winner of many past years, second a good square hen, third nearly as good. The rest of the class are not up to the winners. The five-guinea Selling class brings out but a moderate lot as usual.

Since we put down the above notes a formal protest has been lodged against Mr. J. Walker's cup Dark Dorking pullet to which we alluded, and has been sustained on the ground that she is an old hen; the pen is therefore disqualified.

Cochins.—The first Buff cock is a well shaped bird even in colour, with wonderful foot-feathering, not quite through the moult; second a fresh bird in good condition, with rather more black in tail than we like; third of a really buff hue, smaller in comb than we admire. Among the rest of the class we saw little that took our fancy. Hens are a magnificent class. The two first are about the finest pair we ever saw, with little to choose between them. Third good, but not up to the feathering of the others. No less than seven pens were very highly commended. We greatly admired the form of Mr. Darby's, though she is a little too pale. The first cockerel is a square bird of the old-fashioned type of Cochins, which we much like; his tail is dark. Second is also capital in shape, heavily feathered, and of a rich yellow. Third a very pale bird; we thought his wing a little loose, but we may have been mistaken. Fourth very large, with wondrous feathering. We have scarcely if ever seen such a splendidly feathered collection of Cochins as Mr. Procter's; this bird is, perhaps, a little ungainly, or he must have been placed high. We liked 233,

highly commended (Darby), a large dark bird, and 235 (Lingwood). The cup pullet is a canary Buff, of pretty shape, but not very large; second much hocked, short-backed, and like all her owner's birds in foot-feathering; third a good bird rich in colour; fourth very large, failing a little in colour or she must have been higher. 278 (Mrs. Steven) would be a valuable bird but for some ticking in neck hackle. Taken all round the Buff classes were very remarkable and well filled. Partridge were not quite so numerous. The first cock is not quite through the moult, but a capital bird, specially in feathering; second good, but longer in tail; third much smaller, but well shaped and in fair condition. The first hen is a splendid bird all round; second clear in pencilling, but a little short of feather and narrower; third a big bird with too much comb. If we mistake not we have seen some of Captain Heaton's team in another name this season. The first cockerel is a model in shape, good in colour, but not large; second young-looking and massive; third too big in comb, but very bright in colour, which we think a great point and one rather too little thought of at present. First pullet is splendidly pencilled, but has some tail; second good in shape, with very clear but rather heavy pencilling; third in some ways a falling-off from the first and second, but a good all-round pullet. Mr. Darby's wonderful old White cock bird is again to the fore, looking a little past his prime and hardly through the moult, still his white is glistening and such as we know in no other bird; second must have been near him, a very fine bird in shape and in capital condition, though the least yellow; third fine too. The first hen is well ahead and in capital condition; second an old friend, small, but beautiful in form; third a model of shape, but a little rough from the moult. The first cockerel is the Oxford winner, now a little more yellow. We believe that a protest was lodged against this bird, but not sustained, though not pronounced frivolous. Second a short-legged bird, good in shape, colour, and feather; third a fine cockerel, a little longer on leg than we like. The first pullet (to use an hibernicism) was an old hen. A protest was lodged against the award and sustained, but the card of disqualification was subsequently removed and one substituted to the effect that the bird was exhibited by mistake in a wrong class. We hope to hear some further explanation of this explanation. Second a pretty very white pullet; third a well-shaped hocked bird, but a little yellow. Time failed us to examine the Blacks and Cuckoos satisfactorily, so we must leave them till next week.

Dark Brahmas.—Old cocks are a good class, numbering eighteen. First is a grand hocked bird heavily feathered. He will look much better in a few weeks' time, being hardly through moulting yet. Second is a large bird, rather coarse in head, with a tendency to squirrel tail. We thought he might have given place to the third-prize bird, which, though in poor condition, looked the better of the two. Lady Gwydyr's very highly commended is another good one out of condition. The cup hen is a beautifully marked bird, and good in shape and feather, but we did not like her comb. Second and third are well-made birds, good in marking but not so well feathered as they might be. Miss Shuter's highly commended pair are both of a good sort, densely marked, and look likely to breed good cockerels. We noticed many hens in this class have combs which are very nearly single, a fault which greatly spoils the appearance of the head. Cockerels muster thirty-four pens, which we did not think up to the average of the last few years. The cup went to a well-made hocked bird with the best comb in the whole class. Second is a wide bird also hocked, as in fact are most of the winners in the Brahma classes. This one would probably have taken first had he not had crooked middle toes. Third and fourth are both fair birds, rather loose in comb. The fifth-prize bird will look better in a few weeks, having hardly yet got his hackle. Miss Shuter's very highly commended pen is very good, and we thought 518 (Earle) might have been mentioned. The class for mottled-breasted cockerels is poor. The first is a fair bird, and so is the fourth, but we did not like either second or third. Pullets are a large class (53), and there are many very good birds. The cup was awarded to a beautifully marked one with a most perfect head. She might have had a little more leg-feather with advantage. Second and third are both well-marked birds, good in shape and feather. Fourth is a densely marked pullet, and Miss Hunter's other pens are of the same character, 597 (Peake) is also a very well-marked one, though failing a little on cushion.

Light Brahma cocks are a small but very good class. First is a grand old bird, good in colour and very heavily feathered; second is a well-known winner; third is a good bird, but rather wanting in chest. 633, unnoticed, was the cup cockerel in 1875, and we think fully deserved a very highly commended. The cup hen failed a little in colour, but is otherwise very good. The second and third awards would have been better reversed, as the latter is much the larger of the two, and nearly equal in other points. Fourth is a good bird but rather out of condition. The cup cockerel is a splendid bird, with hardly a fault; second we thought a great mistake, he is hollow-chested, grey on fluff, and very leggy; third is a much better bird, but rather poor in condition, and not as well shown as Mr. Lingwood's birds usually

are; fourth is a good bird heavily marked; fifth and sixth both pretty good. 680 (White), and 613 (Haines) both good pens, and better worth mentioning than some that were highly commended. 704 (Breeze) is also good. Light pullets number nearly fifty pens. The cup went to a very good bird belonging to Messrs. Birch; second, we did not much like, being rather hooked and leggy. Fourth would have very likely beaten her if she had been properly washed. Third is a good one, but rather creamy. Fifth and sixth are both good birds but badly shown. 709 (Evans) a very good pullet, and might have been higher if she had been properly washed.

There is nothing of any great merit in the Selling classes, with the exception of Mr. Lucas's first-prize cockerel, which is much better than many in the open class.

Houdans.—Houdan cocks are a numerous class, but are not correspondingly good. Many are diseased in feet, and many are also backward in plumage; of course these latter will improve with time. First is a fine bird, very large, fine in colour, good in comb, and fairly good in crest, although we should like to see him better in this respect; second large and good in colour, but deficient in crest and bad in feet; third not perfect in comb, but pretty fair in other points. 870 (Lane) is a very good bird. 856 (Howard) a large bird, but fails in crest. 868 (Thomas) is good, but backward in plumage. Houdan hens number twenty-four, and are better than the cocks. First-and-cup a grand hen, very large and good in marking, but scarcely good enough in crest and beard; second is the old champion hen, now growing bad on her feet, otherwise very good, beautiful in marking, fine in crest, and a large bird; third magnificent in crest and good in colour, but poor in body. 879 (Daniel) a fine hen, but a little feather-legged. 884 (Vallance) splendid in colour. 889 (Wood) a beautiful hen, good in feet, fine in crest, and worthy of a prize. 892 (Thomas) a well-known hen, last-year's winner, splendid in crest, but rather light in colour. 895 (Thomas) last year's cup pullet, splendid in crest, but moulted very light. In Houdan cockerels first very dark, splendid leaf comb, large in size, and fair in crest; second a good heavy-bodied bird; third large and good in colour, but rather poor in crest; fourth a good bird of nice colour. 903 (Boissier) good excepting comb. 906 (Rinboul) and 907 (Naylor) are good. 955 and 957 (Dr. Lloyd) are very good Crèves, entered in this class by mistake. In pullets there are thirty-nine entries. First good in body, well marked, and fair in crest; second a good dark pullet, nice crest, and of good size; third an evenly marked pullet with a fair crest; fourth has a good crest. 951 (Vallance) a good pullet. 956 very regularly marked. 962 (Coplestone) very good, rather dark. 959 (Wood) a splendid pullet, one of the best in the class; a good crest, rather dark.

In Crève cocks first-and-cup a most beautiful bird, in fine condition and with good head; very much like a bird that used to be shown by Mr. Feast. Second good in crest and comb; third good in size and comb, but a little white in crest, which does not improve his appearance. 976 (Ward) and 979 (Longman) are both good and very large. Cocks have only nine entries, but hens come out in greater force. First rather small in crest, otherwise very good; second a very good hen if she is not wry-tailed; third fine in size and crest, and in good plumage. 985 (Mackwell) and 987 (Burrell) are good. 988 (Ward) a very fine hen. In cockerels of this variety first is of fine size, crest and comb also good; second splendid except in crest, which is better in front; third very good. In pullets first is a splendid massive bird grand in crest; second very good with a compact crest; third a well-crested pullet. 1013 and 1015 (Höbert), and 1014 (Wood), are good birds.

Hamburgs.—In Golden-spangled Hamburg cocks first-and-cup rather large in comb, good in ears, well marked on breast and wings; second very good in comb, ears, and colour, nice bars and breast; third good in comb and earlobe. In hens, first-and-cup for Spangled Hamburgs is very well marked; second a well-mooned hen; third a well-marked glossy-plumaged bird. In Silver-spangled cocks first very handsome; second a well-marked bird, though he might be rather clearer; third we liked better than second. In hens, first a rather dark but well-marked hen; second a beautiful bird; third a well-mooned hen. In Golden-pencilled cocks first a cockerel good in ears, comb, colour, and tail; second a richly-coloured cockerel with fine head; third well coloured. In hens, first a well-pencilled pullet; second well marked; third good in pencilling and ground colour. In Silver-pencilled cocks, first, which wins the cup, in splendid condition, tail, ears, and comb good; second also good in comb, ears, and tail; third a good bird. In hens, first very sharp and clear in pencilling, also good in other points; second well pencilled; third rather young but well marked. Black Hamburgs mustered well. In cocks first a young bird, very neat in comb and ears; second a fine glossy cockerel, good in head properties; third a good cockerel in fine plumage. In hens the winners are all glossy birds of excellent quality. The Hamburg classes contain many birds of high merit.

Polish.—Golden Poland cocks are the best class of the Polish tribe. First a beautiful bird, in fine plumage and good in crest and markings. Second should not have a place here, as others are his superiors. Third a good bird, which will be better in the

course of a few weeks. In hens—first, a most beautiful pullet, well marked and very fine in crest; second, a very light-coloured hen, not well marked, but large in crest; third is a good hen with excellent crest. In Silver cocks—first, which wins the cup, is a very fine bird with good crest; second and third are both good, but neither are quite ready yet, especially the latter. In hens the winners are all very good birds, capital in crest, although we think we had seen Mr. Adkins turn out better. In the variety Polish class of cocks, first a good untrimmed Black with fair crest; second, a fair bird of the same colour; third, a White of moderate merit. In hens—first a fine and well-known Black; second a beautiful Buff, well marked and good in crest; third a White. In these classes two birds were disqualified for trimming. It is time the matter was settled; if trimming is to be illegal, which we should be glad to see the case, the fact should be made known. We think some more birds in these two classes might have been selected for this distinction.

THE PIGEONS.

This I believe is the tenth regular annual Show at the Palace—I am not sure whether it is not the twelfth. There was a time long, almost long long, when there was a show there for a year or two, when heads now grey were brown, or scalps now bald were well thatched; then came a pause, and then the regular annual exhibition, which is indeed the Derby of the fancy. The Palace has therefore been very true to us. The Alexandra and the Aquarium flirted with the fancy and then broke acquaintance, but the old palace of glass at Sydenham is true as steel. It is the fanciers' trysting place, where we are sure to meet, even if we meet not any time besides. This year I understood that a circus had taken up the transept, that a lot of galloping horses had intruded themselves, and consequently I went in no amiable mood, not liking the old place to be so used and the associations of years to be so broken. However, I quickly changed my mind when once at the Show. From end to end the grand nave was full of birds. From the first entrance, where the kings and queens look down, was the poultry up to the transept, then the circus—a not-bad break; then on the whole length, in three lines, came the Pigeons up to tropical department, yea, within it still Pigeons; so that from end to end the fancy was in possession of the whole length of the long building. It was the old friend with a slightly new face, but an improved face, for the Show gained in importance by this arrangement. But what about the quality of the Pigeons? I venture to say it was the very best Show ever seen—in number of pens over sixteen hundred, in quality as yet unsurpassed.

One first remark before describing the classes. The whole of Monday must in future be given up to the Judges. When I left, at seven o'clock in the evening, the whole of the cards were not on, and I cannot wonder, for Judges are rightly careful, and the quality of the birds added to the number makes a great difficulty. Now for the pens.

Pouters, originally from imitation of Glasgow Show, put first. Blue Pieds and Whites the cream; first, second, third, and extra third prizes for cocks of the former colour. Blacks.—The first-prize excellent. The cup Red (2555) elegant. No Yellow took a prize among the old birds. Among the Pouters of this year the cup hen (Beckwith), once owned by Mr. Bullen, a superb bird; also the first Blue hen, very choice. *Pigmies* much as usual.

Carriers.—The champion class select, and but few as natural. The cup Black cock (2665) very grand, especially as he faced one; beak foremost to the eye. The Black hens were even superior to the cocks. First-prize (2680) wonderfully out of moult. It looked as if it had fallen into the pig tub. Dun hens better than cocks. Blues an advance. Cup (2735) good *jev*, and one of the best birds ever seen. Blue hens very good as well. Other coloured Carriers, chiefly Whites, but first-prize a Silver Dun; third a good Silver; second White and large. Of the Carriers of 1878 (the youngsters) they are a capital racey lot of birds; most promising. The Judges, who are always fond of the rule of three, gave even a fourth prize in the cocks. Cup hen (Blacks) sold for £50.

Dracons an enormous class. Blues most excellent as to prize birds, pure in colour and fine in points. Many besides the winners first-rate. Mr. Woods is a wonderful winner. Many a man would be a Mr. Woods if he could! Beautiful brown-barred Silvers, good deep-coloured Reds and Yellows, Whites not quite so good. The young Dracons promise well.

Almond Tumblers.—Cup cock a bird of colour. Hens.—First prize (3188) sound in ground colour, that difficult point, as also second-prize. The Short-faced Balds and Beards more numerous than formerly. Red and Yellow Agates and a whole Red took prizes among the cocks, while a Kite headed the hens. The *Barbs* scarcely so numerous as usual I fancy, but the names of Fulton, Maynard, Ecroyd, and Hedley suffice to prove their excellence. *Jacobins* hard indeed to judge, so level were the best. Reds deeper in colour than formerly, and abundance of stuff in them. Yellows.—Cup (3367) superb in hood and chain. Black.—Cup (3395) perhaps the best ever shown. The Whites still few, and a coloured one took one of the three prizes. *Fantails.*—In these birds the Judges have gone back to more of the English style—less motion stouter birds. Mr. Cresswell's tasty dainty hen only third. A

good Black of Miss Dickinson's was first among the Coloured Fans. *Nuns* more numerous than usual. *Trumpeters* very few, but very choice. *Owls* very abundant, and among them a few Powder-blue, but not quite what they were years ago. *Englis* strong and good, Foreign but few; but both included made huge classes. *Turbits* again evidently great favourites, the classes being overwhelming. A new class—namely Turbiteens, which, though but six in number, were highly deserving. A capital show of *Maggies*, a strong class of Archangels, which I feared were a dying-out variety, *Runts* looking up and weighing down heavily, a nice clean pretty class of flying Tumblers. *Antwerps*, very numerous. Some of these and the Selling class were in the tropical department, together with those gems of gems the cages containing the best collection of four pairs of Pigeons, exclusive of Carriers and Pouters. Mr. Salter was first with a cage of *Maggies*, *Owls*, *Jacobins*, and *Turbits*. Second, third, and even fourth prizes followed; Beckwith, Maynard, and Fulton having the honours in rotation as placed. Special flying classes of homing *Antwerps* finished up the Show, which I again state as being the best exhibition ever seen in England.

The new arrangement will, I hope, be adhered to in future years. Long lines of pens are better than short ones; the Show is less broken into bits, and non-fanciers see the birds in a more imposing and therefore more attractive state.—WILTSHIRE RECTOR.

POULTRY.

DORKINGS.—*Cock*, *Red-Cock*.—H. H. Lingwood, 3, R. W. Beachey, *chc.* O. E. Cresswell, *Hen*.—1 and Cup, F. Parlett, 2, J. Walker, 3. Mrs. R. Wood, 4 and *chc.* T. Briden. *Cockerel*.—1, Cup, and 2, J. A. & M. S. Smyth, 3, W. G. Mulligan, 4, T. W. & L. Hind, 5, Rev. R. S. S. Woodgate. *Hens*.—J. Taylor, T. C. Burnell (2). *Pullet*.—1 and Cup, J. Walker, 2, Rev. H. R. B. Jones, 3, J. Everett, 4, T. C. Snell, 5, J. Taylor, *chc.* J. Taylor, T. C. Burnell. *Silver-Laced Game*.—1 and Cup, E. W. Beecher, 2, J. Taylor, 3, Miss Parlett, 4. *Leg-Hen*.—1 and 2, T. C. Burnell, 3, Miss Parley, *chc.* R. A. Boissier. *Cockerel*.—1 and Cup, O. E. Cresswell, 2, W. G. Mulligan, 3, P. Ogilvie. *Pullet*.—1, Mrs. Wachter, 2, O. E. Cresswell, 3, W. Roe, jun. *Bur or Cuckoo*.—1, H. H. Young, 2, W. Bishop, 3, R. Peake. *White-Cock*.—1 and Cup, O. E. Cresswell, 2, W. Roe, jun., 3, H. H. Young. *Blue-Cock*.—1 and Cup, R. A. Boissier, 2, H. H. Young, 3, R. Peake. *Blue-Game*.—1 and Cup, R. A. Boissier, *chc.* Rev. F. Tearle, Mrs. M. A. Hayne, H. J. Ivery. *Auc d'Or*.—1, M. Leno, jun, 2, F. Parlett, 3, Mrs. J. L. Logan, 4, T. Briden.

COCHINS.—*Cinnamon or Buff*.—*Cock*, 1, T. P. Ye. 2, W. Wright, 3, Mrs. A. Christy. *Hen*,—1, Cup, and 2, G. H. Procter. 3, Mrs. Alsopp. *ehc*, A. E. W. Darby, 3, J. O. Rigg, Capt. A. F. Lendy, Mrs. H. Shutt, J. Cattell, Mrs. W. Paxon. B. Smith. *Cockerel*.—1 and 2, T. P. Ye. 3 and 4, G. H. Procter. *ehc*, H. Lindwood. *Pullet*.—1 and Cup, Lady Gwydyr. 2, G. H. Procter. 3, E. Burrell. 4, W. Wright. *ehc*, W. P. Myland, G. H. Wood, T. Jenkins. *Partridge*.—*Cock*, 1, J. J. Wood. 2, R. P. Percival. 3, H. Tomlinson. *Hen*.—1, Capt. H. Heaton. 2, J. J. Wood. 3, E. Audman. *ehc*, J. F. Saltmarsh, R. P. Percival. *Cockerel*.—1, Cup, and 2, H. Heaton. 3, H. Tomlinson. *Pullet*.—1, Capt. H. Heaton. 2, Mrs. Gordon. 3, Capt. H. Heaton. *ehc*, R. R. Fowler & Co., G. B. C. Breze. *White*.—*Cock*,—1, A. E. W. Darby. 2, P. H. Chase. 3, J. T. Holmes. *ehc*, H. Tomlinson. *Hen*.—1, H. Tomlinson. 2, R. R. Fowler & Co. 3, A. E. W. Darby. *Cockerel*.—1, P. H. Chase. 2, Mrs. J. Percival. 3, A. E. W. Darby. *ehc*, C. & E. Naylor. *Pullet*.—1 and Cup, R. P. Turner. 2 and *ehc*, R. R. Fowler & Co. 3, P. H. Chase. *Black*.—*Cock*,—1, A. E. W. Darby. 2, Lady Gwydyr. 3, Miss Lightfoot. *Hen*.—1 and 2, A. E. W. Darby. 3, Mrs. J. Turner. *Cockerel*.—1, Mrs. J. Turner. 2, E. Kendrick, jun. 3, J. Mansfield. *Pullet*.—1, E. Kendrick, jun. 2, T. W. Fletcher. 3, Lady Gwydyr. *Black*.—*Cock*,—1 and 2, J. H. Cunn. 3, T. Aspden. *Any variety*.—1, J. Bloodgood. 2, Mrs. Aspden.

2. *Blackwork*, 2. *Mr. Gordon*, 3. *P. Ogilvie*,
 4. *W. Braham*, *Dark—Cock*—1, E. Kenrick, jun., 2. *L. C. R. Norris*, 3. *G. W. Percival*, *Light—Lady Gymp*, *Hen*, and Cup, E. Pritchard, 2. *R. P. Percival*, 3. *Rev. T. H. Horsfall*, *Dark—Cock*—1 and Cup, J. Wood, 2 and 4. *L. C. R. Norris*, 3. E. Pritchard, 5. J. Gilbert, *The Misses Shuter*, *L. C. C. R. Norris*, *Dark Mottled-breasted—Cockerel*—1, Dr. J. Macrae, 2. J. Gilbert, 3. E. Kendrick, jun., 4. R. P. Percival, *Dark—Pullet*—1 and Cup, H. Lingwood, 2. J. Wood, 3. R. P. Percival, 4. Miss E. Shuter, 5. T. Pye, 6. E. Kendrick, jun. *chc*, *Rev. T. C. Peake*, *Selling Class*—1, R. A. Baker, 2. E. Kendrick, jun., 3. G. Bennett, 4. T. F. Ansell, *Light—Cock*—1, J. Mitchell, 2. H. C. White, 3. S. Lucas, 4. Dr. G. A. Angier, *Hen*—1 and Cup, J. & W. Birch, 2. Dr. E. Snell, 3. G. W. Petter, *Cockerel*—1 and Cup, G. W. Petter, 2 and 3. G. B. C. Breeze, 3. H. Lingwood, 4. *Lady Gymp*, 6. T. Evans, *Pullet*—1 and Cup, J. & W. Birch, 2. G. Petter, 3. F. Haines, 4. T. Evans, *Lady Gymp*, 5. H. C. White, *chc*, G. C. G. G. G. *Selling Classes*—*Light*—1, A. I've, 2. G. W. Petter, 3. F. Haines, 4. J. Windred, 5. Dr. G. A. Angier, *Dark or Light—Hens or Horses*—1, R. P. Percival, 2. J. A. Beames, 3. M. Leno. sen., 4. G. W. Petter,

SPANISH.—*Cock*.—1 and Cup, D. M. Mills. 2 and 3, W. R. Bull. *Hen*.—1 and 2, P. F. Le Sueur. 3, G. Thomas. *Cockerel*.—1, P. F. Le Sueur. 2, J. F. Dixon. 3, J. Powell. *Pullet*.—1, J. Woods. 2, A. Bell. 3, J. Powell.

HOUDANS.—*Cock*.—1, Mrs. Vallance. 2, A. Ogden. 3, W. H. Copplestone.
Hen.—1 and Cup, J. Graham. 2, Mrs. Vallance. 3, A. Ogden. *viz.*, S. W. Thomas. *Cockerel*.—1, R. B. Wood. 2, G. D. Harrison. 3, C. & E. Naylor. 4, A. Rimboul, jun. *Pullet*.—1, R. A. Boissier. 2, G. D. Harrison. 3, W. Nicholls. 4, A. Rimboul, jun.

CREVE-CŒURS.—*Cock*—1 and Cup, Mrs. E. Dorset. 2, W. R. Park. 3, E. Burrell. *Hen*—1, H. Stephens. 2, W. Wilkins. 5, G. W. Hibbert. *hic*, J. Ward. *Cockerel*—1, J. Ward. 2, W. R. Park. 3, R. B. Wood. *Pullet*—1, E. Burrell. 2, R. R. Fowler & Co. 3, J. Ward.

HAMBURGHs.—*Golden-spangled*, *Cock*—1, J. Jackson, 2 and 3, C. & W. May. *Hen*—1 and Cup, J. Jackson, 2, H. Beldon, 3, T. Blakeman. *Silver-spangled*—*Cock*—1, J. Fielding, 2 and 3, H. Beldon. *Hen*—1 and 3, H. Beldon. 2, Ashton & Booth. *Golden-pencilled*—*Cock*—1, Miss D. Mackenzie, 2, H. Bourne, 3, J. Long. *Blue*, T. F. Carver, Dr. E. Snell. *Hen*—1, J. Smith, 2, J. T. Castell, 3, J. Calcutt. *Black*—*Cock*—1, Cup, and 3, H. Beldon, 2, *Hen*—1, H. Beldon, 2, J. T. Castell, 3, J. Long. *Black*—*Cock*—1, Stott & Booth. *H. Beldon*, 3, J. Pickup, 4, J. W. Kelleway, J. Long. *Hen*—1, J. H. Howe, 2, L. Barnett, 3, J. W. Kelleway.

GAME-Black R. Cock—1, H. H. Hall, 2, T. P. Lyon, 3, Hon. & Rev. F. Dutton. *vhc*, A. H. Randall, S. Mathew. *Cockerel*—Cup, S. Mathew, 2, S. Mathew, 3, W. P. Pope, 4, T. P. Lyon. *Hen*—1, R. Garnett, 2 and 3, W. J. Pope. *Pullet*—Cup, W. J. Pope, 2, Dr. Etheridge, 3, J. H. Haisall, 4, S. Mathew. *vhc*, R. K. Lempiere. *Brown Red*—Cock—Cup, H. E. Martin, 2, W. A. Fenwick, 3, S. Mathew. *Cockerel*—1 and Cup, R. Taylor, 3 and 4, H. E. Martin. *Hen*—1, H. E. Martin, 2, H. H. Hall, 3, J. H. Goodwin, 4, V. S. Haisall. *Pullet*—1, F. Warde, 2, W. Watson, 3, W. Webster. *vhc*, F. Fenwick. *Dutch*—*ving*—Cock—1, H. E. Martin, 2, A. Cameron, 3, H. E. Martin. *Cockerel*—1, S. Mathew, 2, H. E. Martin, 3, D. Harley. *Hen*—1, S. Mathew, 2, T. P. Lyon, 3, D. N. J. Thomas. *Pullet*—1, D. Harley, 2, J. A. & H. H. Staveley, 3, J. Craven & Son, 4, J. Goodwin. *Any other variety*—Cock—1, W. Adams, 2, J. Haisall, 3, H. H. Hall. *Cockerel*—Cup, and 3, J. Colgrove, 3, F. J. Nalder, 4, H. H. Hall. *Hen*—1, H. H. Hall, 2, J. Colgrove, 3, F. J. Nalder, 4, W. J. Pope. *Pullet*—1, J. H. Haisall, 2, W. J. Pope, 3, J. Colgrove, 4, W. R. Smith. *Selling Class*—1, W. A. Swan, 2, H. M. Maynard, 3, J. Braithwaite, jun.

MALAYS.—*Cock*—1, J. S. Bater. 2, J. Downing. 3, J. F. Walton. *Hen*—1, T. Eaves. 2, R. Hawkins. 3, T. B. Lowe.

POLISH.—*Golden-splunged*—1, E. Burrell. 2, Mrs. E. Dorset. 3, H. E. Brant. *Hen*—1, E. Burrell. 2, Rev. C. W. Shepherd. 3, G. W. Boothby.

Silver-splunged—*Cock*—1, Cup. and 2, G. C. Adkins. 3, A. & W. H. Silvester.

Hen—1, 2, and 3, G. C. Adkins. *Black, or any other colour*—*Cock*—1, Dr. E. Lloyd. 2, J. North. 3, H. W. Reville. *Hen*—1, T. Norwood. 2, H. Beldon. 3, H. W. Reville.

LEIGHORNS.—*Brown*.—Cock.—1 and Cup, R. Strong. 2, R. D. Wood. 3, J. C. Fraser. *Hen*.—1 and 2, W. Philcox. 3, E. Ayre. *White*.—Cock.—1, Bradbury Bros. 2, R. Harvey. 3, J. C. Fraser. *Hen*.—1 and Cup, Mrs. Troughton. 2, J. C. Fraser. 3, T. Norwood. *vhc*. Miss Handfield.

ANDALUSIANS.—Cock.—1 and Cup, Mrs. Troughton. 2, Mrs. Cross. 3, M. W. L. Brook. Hen. 1, W. Wildey. 2, M. A. Wilson. 3, Rev. S. Ashwell.

SULTANS.—Cup, Mrs. T. W. S. Damant. 2, Mrs. A. Christy. 3, C. Atkinson.
LANGSHANS.—Cup, Miss Mill. 2, Miss Willcox. *Cockerel*.—1 and Cup, G.
Heaselden. 2, R. H. Bush. 3, W. Morris. *Pullet*.—1, S. Coweles. 2, W. Morris.

ANY OTHER VARIETY.—1, Rev. R. S. S. Woodgate. 2, R. R. Fowler & Co. 3, R. J. Brewer.

SELLING CLASSES.—*Dorkings, Brahmas, or Cochins.*—Cock or Cockerel.—1, S. Lucas. 2, C. & E. Naylor. 3, J. Virgo. 4, J. Buckmaster. 5, Dr. G. A. Angier. *Hens or Bantams.*—1, J. Virgo. 2, J. Buckmaster. 3, E. Parlett. 4, E. Parlett. 5, Dr. G. A. Angier.

[illegible]

J. A. W. Darley.
 1. GAME BANTAMS.—*Black Red*.—Cock—1 and cup, T. W. Anns. 2. *E. Walton*.
 2 and 4, W. F. Addie. 3, W. Shaw. *Hen*.—1 and cup, F. W. R. 2, W. F. Addie.
 3, W. Adams. 4, *Green Neck*.—Cock—1, W. F. Addie. 2, J. H. & A. Stretch.
 3, E. Walton. *Hen*.—1, J. H. & A. Stretch. 2, E. Walton. 3, S. Brighton. *Duckling*.—Cock—1, J. Smith. 2, M. A. Wigham. 3, S. Brighton. *Hen*.—1, E. Walton. 2, J. Nelson. 3, George Hall. *Pile*.—Cock—1 and cup, E. Walton.
 2, R. Brownlie. 3, G. Hall. *che*. R. Brownlie. W. F. Addie. *Any colour*.—Cock—1, W. F. Addie. 2, R. Brownlie. 3, F. Davis. *Selling class*.—1, R. Brownlie. 2, E. Walton. 3, J. H. & A. Stretch.

1. B. A. Adams. *Birds*.—Cherish. 2. E. W. H. Shackleton. 3. S. Clapham. *Booted*,
 any colour.—1. Mrs. Troughton. 2. W. Lowes. 3. W. Adams. *Sebright*.—1. E.
 Walton. 2. Rev. F. Teagle. 3. M. Leuco. *Chc. A. Pratt*. Any other distinct
 variety.—T. F. Phelps. 2. W. O. Hodges. 3. Mrs. Brassey. *Any variety except*
Game.—Selling class.—1. J. Lushington. 2. J. Cockroft. 3. G. Griggs. *Any*
variety.—Selling class. 1. G. Hall. 2. A. & W. H. Sylvester. 3. C. Martin.
 DUCKS.—Aylesbury.—1 and cup, R. R. Fowler. 2. J. Hedges. 3. E. Snell.
ric. T. Sear. *Pekin*.—1 and cup, R. R. Fowler. 2. W. Bygott. 3. E. Snell. 4.

 J. Newton. 4. J. A. Barber. *Kouen*.—1 and cup, R. R. Fowler. 2. A.
 & W. H. Sylvester. *Black*.—1 and cup, J. A. Barber. 2. J. Malden. 3. Miss E.
 Browne. 4. R. M. Hayne. 4. L. W. Kellaway. *Any other variety*.—1. Rev.
 W. Sergeantson. 2. H. J. Ludlow. 3. J. Trickett. *Selling class*.—1. T. Wake-
 field. 2. H. Allen. 3. J. Hedges. GEESSE.—Cup, J. Everett. 2. J. & W. Birch.
 3. Captain L. Anyon.

TURKEYS.—*Any variety*.—Cup, Mrs. A. Mayhew. 2, J. & W. Birch. 3, F. Warde. *Any variety*.—*Cockerel*.—1 and 2, W. Wykes. 3, H. J. Gunnell. *Any variety*.—*Hen*.—1, Rev. N. J. Ridley. 2 and 3, W. Wykes.

PIGEONS.

POUTERS.—*Blue-necked-Cock*, 1, W. Nottage, 2, J. Baker, 3, J. Guthrie, *rch*, J. Dye. *Hen*, 1 and 3, J. Baker, 2, E. Beckwith. *Black-pied-Cock*, 1 and 3, R. Fulton, 2, J. Baker. *rch*, R. Fulton, J. Baker. *Hen*, Cup 1, and 2, J. Baker, 3, J. D. Lang. *Red or Yellow-pied-Cock*, Cup and 1, J. Dye, 2, R. Fulton, 3, J. D. Lang. *rch*, 1, R. Fulton, 2, J. D. Smith. *Black-Cock*, *rch*, Al. H. Gill, J. Dye. *White-Cock*, 1 and 2, J. Baker, 3, E. Beckwith. *rch*, Rev. W. C. Bullen, J. Dye. *Hen*, Cup and 1, E. Beckwith, 2, Rev. W. C. Bullen, 3, J. D. Lang. *rch*, J. H. Smith, J. Dye. *Any Colour-Cock*, Cup and Challenge Cup, Rev. W. C. Bullen, 2, R. Fulton, 3, E. Beckwith. *rch*, G. D. Webb, D. D. Combe. *Any Colour-Cock*, Cup and 1, H. W. Webb, *rch*, E. Beckwith, D. Combe. *Pigmy or Austrian-Cup* and 1, H. W. Webb, 2, R. Fulton, 3, Dr. E. Hicks.

CARRIERS.—*Blue-Cock*,—Cup, 1 and 2, Capt. H. Heaton, 3, H. Stephens. H. M. Maynard. *Hen*,—1, R. Fulton. 2 and 3, Capt. H. Heaton. *ehc*, R. Fulton; 2, Hallam. *Young Cuck*—1 and Cup, H. Heritage. 2, H. Stephens. 3, Cucksey & Plicker. 4, H. Parker. *ehc*, J. E. Palmer; F. Cox; W. G. Hammond. *Young Hen*—1 and Cup, H. M. Maynard. 2, Capt. H. Heaton. 3, G. Winter. *ehc*, R. Fulton; H. Goodman. *Dun-Cock*,—1 and 2, Capt. Heaton. 3, R. Ecroyd. *ehc*, R. Ecroyd; R. Fulton. *Hen*,—Cup, 1, and 2, R. Fulton. 3, H. M. Maynard. *Young Cuck*,—1, T. Hallam. 2, H. Stephens. 3, F. Cox. *Young Hen*,—1, E. Burton. 2, H. Heritage. 3, R. Fulton. *Blue-Cock*,—1 and 2, H. M. Maynard. 3, R. Cant. 4, G. H. Gilliam. *ehc*, W. H. Reid. *Young Cuck*,—1 and Cup, R. Fulton. 2, H. M. Maynard. 3, R. Cant. 4, G. H. Gilliam. *ehc*, W. H. Reid. *Young Hen*,—1, G. H. Gilliam. 2, Dr. G. F. Jones. 3, R. Fulton. *Young Cuck*,—1, H. M. Maynard. Cucksey & Plicker. 3, C. Clarke. *Selling Classes*.—*Cock*,—1, H. Parker. 2 and 3, H. Maynard. *Hen*,—1, H. M. Maynard. 2, J. Reid. 3, C. G. Cave.

FLA. DRAGONS.—*Blue*.—*Cock*—1 and Cup, E. Burton. 2, R. Woods. 3, W. G. Flanagan. 4, A. McKenzie. *whc*, T. C. Burnell. *Hen*—1 and W. Smith. 2 and 3, R. Woods. *Silver, Black-bars*.—*Cock*—1 and 3, R. Woods. 2, W. G. Flanagan. *whc*, A. McKenzie; T. C. Burnell. *Hen*—1 and Cup, A. McKenzie. 2, T. Burnell. 3 and *whc*, R. Woods. *Brown-bars*.—*Cock*—1, 2 and 3, W. Bishop. *Hen*—1 and Cup, A. McKenzie. 2 and 3, W. Bishop. *Yellow*.—*Cock*—1, R. Woods. 2 and 3, A. Leith. *Hen*—1, R. Fulton. 2, W. Sargent. 3 and *whc*, R. Woods. *Red*—1, W. Sargent. 2, A. Leith. 3, R. Woods. *whc*, G. H. Thomas. *White*—1, R. Fulton. 2, R. Woods. 3, W. Bishop. *whc*, J. Guthrie. *Any other Colour*.—*Cock*—1 and 2, T. C. Burnell. 3, A. McKenzie. *whc*, R. Woods. *Hen*—1, A. McKenzie. 2 and 3, R. Woods. *Blue or Silver, Black-bars*.—*Young Cock*—1, J. Lush. 2 and 3, R. Woods. 4, G. H. Thomas. *whc*, W. G. Flanagan. *Young Hen*—1, W. G. Flanagan. 2 and 3, R. Woods. *whc*, T. C. Burnell. *Yellow* or *whc*.—*Young Cock*—1 and Cup, W. Sargent. 2 and 3, A. Leith. *Young Hen*—1 and *whc*, A. Leith. 2, F. P. Ellis. 3, W. Sargent. *Silver, Brown-bars, or any other Colour*.—*Young Cock*—1, A. McKenzie. 2, R. Woods. 3, W. Bishop. *Young Hen*—1 and 2, W. Bishop. 3, R. Woods. *Any Colour*.—*Cock*—1, W. Sargent. 2, J. Lush, jun. 3, R. Woods. *whc*, A. Leith. *Hen*—1, C. Howard. 2, R. Woods. 3, M. J. Hose.

TYMBLERS—*Almond*—Cock—1 and Cup, R. Fulton. 2, J. M. Braid. 3, T. Hallam. *Hen*—1, 2, and 3, R. Fulton. *Young Bird*. 1 and 2, T. Hallam. 3, J. M. Bott. *Any other Variety*—Cock—1, J. Baker. 2, H. R. Tenney. 3, M. and J. Weston. *Hen*—1, G. H. Stevens. 2, J. M. Braid. 3, T. Hallam.
BARBS—*Black or Dun*—Cock—1 and Cup, M. Hedley. 2, J. Baker. 3, Wood. *Hen*—1 and *the* M. Hedley. 2, J. Baker. 3, W. Harrison. *Any other Colour*—Cock—1 and Cup, R. Fulton. 2, R. Ecrody. 3, M. Hedley. *Hen*—1, R. Fulton. 2, R. Woods. 3, M. Hedley. *Young Cock*—1 and Cup, R. Fulton. 2 and 3, M. Hedley. *Young Hen*—1, M. Hedley. 2 and 3, H. M. Maynard.
JACOBS—*Red Cock*—1, S. Salter. 2, H. Heritage. 3, J. Eyer. *Any other Colour*—Cock—1, S. Salter. 2, H. Heritage. 3, J. Eyer. *Hen*—1, S. Salter. 2, H. Heritage. 3, R. Fulton. *Any other Colour*—Cock—1, S. Salter. 2, H. Heritage. 3, R. Fulton. *Any other Colour*—1 and Cup, and *the* H. Heritage. 2 and 3, S. Salter. *Any other Colour*—1 and *the* S. Salter. 2 and 3, R. Fulton.

FANTAILS.—White.—Cock.—1 and Cup, O. E. Cresswell. 2, H. Goodman. 3, J. Water. *Hen*—1, H. Goodman. 2, J. F. Loveridge. 3, O. E. Cresswell. Any other Colour.—Miss Dickinson. 2, W. F. Footitt. 3, J. Taylor.

TRUMPETERS.—1 and 3, J. Lederer. 2, J. Baker.

OWLS.—English, Blue.—Cup.—1, and 2, S. Salter. 3, J. Barnes. English, Powder-Blue.—1 and 3, S. Salter. 2, R. Ercroyd. English, Silver.—Cock.—1, R. Ercroyd. 2 and 3, S. Salter. English, any other Colour.—1 and 2, S. Salter. 3, W. Merdith. English, Blue.—1 and 2, S. Salter. 3, E. W. Van Senden. *Hen*—1, J. Barnes. English, Silver.—1 and Cup, S. Salter. 2, J. Dye. 3, Ward and Lister. English, Powder-Blue or Silver, or any other Colour.—1 and 2, S. Salter. 3, J. Barnes. English, Blue or Silver.—Cup, 1, 2, and 3, S. Salter. English, Powder-Blue or Silver, or any other Colour.—1, 2, and 3, S. Salter. Foreign.—1 and Cup, J. Sparrow. 2, E. Beckwith. 3, Dr. J. Bowes. *Hen*—1, S. Salter.

TURBITS.—Blue or Silver.—Cock.—1, S. Salter. 2, R. Woods. 3, H. R. Tenney. *Hen*—Cup, G. Webster. 2, S. Salter. 3, T. C. Burnell. Red or Yellow.—Cock.—1, J. Baker. 2, T. C. Burnell. 3, C. A. Crafer. Any other colour.—Cock.—1, R. Woods. 2, R. Ercroyd. 3, T. C. Burnell. *Hen*—1, C. A. Crafer. 2, O. E. Cresswell. 3, R. Woods. Young.—1, J. Dye. 2, T. C. Burnell. 3, G. Webster. Young.—Cup, O. E. Cresswell. 2, C. A. Crafer. 3, S. Salter. TERBITEENS.—1, J. A. Winsloe. 2, H. W. Webb. 3, F. Winsler.

MAGPIES.—Black.—Cup, F. P. Bulley. 2, S. Salter. 3, F. P. Bulley. Red.—1, F. P. Bulley. 2, S. Salter. 3, W. Tidd. Yellow and any other colour.—1, J. Young. 2, J. F. Harvey. 3, F. P. Bulley.

ARCHANGELS.—1, S. Salter. 2, W. R. Rootes. 3, F. P. Bulley.

RUNTS.—1, H. Stephens. 2, H. Yardley. 3, J. S. Price. Young.—1, 2, and 3, J. S. Price.

FLYING TUMBLERS.—Bald or Bearded.—1, R. Woods. 2, J. Barnes. 3, C. W. Hobbs. Long-faced, any other variety.—1, Miss F. Frith. 2, H. E. Yates. 3, J. Mallett.

ANTWERPS.—Short-faced.—1, 2, and 3, R. Ercroyd. *Homing Blue or Blue-checked*.—Cock.—1 and 4, B. W. Browne. 2, G. Carvill. 3, C. Howard. *Hen*—1, J. Robertsshaw. 2, J. Wightman. 3, Wiggins. 4, S. R. Pearce. *Homing, any other colour*.—Cock.—1, G. Naden. 2 and 4, G. J. Lenney. 3, M. Bell. *Hen*—1, C. Howard. 2, G. Webster. 3, Cox and Norris. 4, F. W. Benham. *Hen*—1, B. W. Browne. ANY OTHER VARIETY.—1, J. S. Stephenson. 2, J. A. Winsloe. 3, J. Long. Special Flying Class of *Homing*.—Cock.—1, S. R. Pearce. 2, G. Burgess. 3, E. Wormald. 4, J. James. 5, J. J. Sparrow. *Hen*—1, W. Stephenson. 2, C. Payne. 3 and 5, G. J. Lenney. 4, F. W. Benham.

SELLING CLASSES.—Cock.—1, H. M. Maynard. 2, J. Reid. 3, W. Nottage. 4, J. Murphy. *Hen*—1 and 2, H. M. Maynard. 3, W. Dale. 4, T. Wicks. *Red*.—1, H. M. Maynard. 2, E. W. Van Senden. 3, D. Young. 4, D. Knight. *Hen*.—W. Dale. R. Woods. G. Murphy.

BEST COLLECTION OF FOUR PAIRS OF PIGEONS EXCLUSIVE OF CARRIERS. AND POUTERS.—1, S. Salter. 2, E. Beckwith. 3, H. M. Maynard. 4, R. Fulton.

BEST PAIR OF ANY VARIETY BRED IN 1878, EXCLUSIVE OF CARRIERS, POUTERS, BARBS, AND TUMBLERS.—1, G. H. Thomas. 2, J. Bowes. 3, R. Woods. *Hen*. J. Schweitzer.

DERBY CANARY AND ORNITHOLOGICAL SOCIETY'S SHOW.

THE twenty-first annual Exhibition of Poultry, Pigeons, Rabbits, Canaries, and British and foreign birds, was held in the Royal Drill Hall, Derby, on the 8th and 9th inst., when the following prizes were awarded:—

POULTRY.—DORKINGS.—1 and 2, B. Smith. 3, J. Stott. *Hen*. W. H. Crewe. COCHINS.—1, Dr. E. V. Snell. 2, H. Tomlinson. 3, T. C. Morris. *Hen*. G. Richardson. BRAHMAS.—Dark.—1, T. S. Clarke. 2, G. W. Henshall. 3, W. H. Edmondson. *Hen*. G. A. Eastwood. Light.—1, T. S. Clarke. 2, Mrs. L. Turner. 3, H. Hurst. *Hen*. G. N. Viscroft. GAME.—Black Red.—1, J. F. Hollingworth. 2, W. Green. 3, C. Spencer. *Hen*. T. Whitehead. Broken Red.—1, J. Calladine. 2, R. Ashley. 3, A. Piggitt. *Hen*. E. Waters. Any other variety.—1, J. Stoppard. 2 and 3, Mrs. E. Bell. *Hen*. J. Frith. Any variety.—Cock.—1, J. Frith. 2, Mrs. E. Bell. 3, R. Taylor. *Hen*. G. Brentnall. HAMBURGS.—Gold or Silver-pencilled.—1, J. W. Beale. 2, E. East. 3, C. Pickering. *Hen*. R. Fletcher. Gold or Silver-spangled.—1, T. E. Jones. 2, W. Boocking. 3, T. May. *Hen*. F. H. Smith. FRENCH.—Houdans, Creves-Cour, &c.—1, Mrs. H. Revill. 2, L. Booth. 3, G. Foster. SPANISH.—Andalusians, Minorcas, &c.—1, J. Watson. 2, J. F. Herrieh. 3, T. S. Sultans.—1 and 2, E. J. Eyles. 3, Rev. J. P. Wright. 3, T. Whitehead. BANTAMS.—Game.—1, S. Beighton. 2, Bros. Cooper. 3, T. H. & A. Stretch. *Hen*. A. E. Ward. Any other variety except Game.—1, T. Watchorn. 2, E. C. Wallace. 3, W. D. Osceit. *Hen*. J. Wall. ANY OTHER VARIETY.—1, Mrs. T. W. Fletcher. 2, J. Pickup. *Jun*. 3, Miss M. Whitehead. *Hen*. A. Fletcher. SELLING CLASSES.—Dorkings, Cochins, and Brahmans.—1, Mrs. H. Radford. 2, W. P. Nock. 3, B. Smith. *Hen*. S. T. Vernon. Any other variety.—1, T. Charvill. 2, J. S. Watson. 3, Barnesby & Heath. 3, W. Thorne.

PIGEONS.—CARRIERS.—1 and 2, J. H. Smith. 3, H. Yardley. *Hen*. T. H. and A. Stretch. POUTERS.—1, J. C. Waterhouse. 2, J. Hawkins. 3, T. H. and A. Stretch. *Hen*. T. Shaw. DRAGONS.—Blue or Silver.—1, 2, and 3, R. Woods. 3, A. McKenzie. Red or Yellow.—1, A. McKenzie. 2, 3, and 4, R. Woods. Any other variety.—1, 2, and 3, R. Wood. 3, G. Cowlishaw. BARBS.—1, Withheld. 2, R. Woods. 3, H. Yardley. TUMBLERS.—Almond.—1 and 2, M. & A. Weston. 2, H. Yardley. *Hen*. J. C. Waterhouse. Any other variety of Short-faced.—1, H. Yardley. 2, 3, and 4, M. & A. Weston. Long-faced Clean-legged.—1, 2, 3, and 4, R. Woods. 2, J. C. Bott. Long-faced Feather-legged.—1 and 2, H. Yardley. 3, J. Darby. FANTAILS.—1, W. Green. 2 and 3, J. F. Loveridge. 3, J. H. Smith. TURBITS.—Blue or Silver.—1, 2, and 3, R. Woods. 3, T. H. and A. Stretch. Any other colour.—1, 2, and 3, R. Woods. 2, Taylor and Harker. OWLS.—English.—1, H. Parker. 2, T. H. & A. Stretch. 3, R. Woods. *Hen*. J. C. Waterhouse. Foreign.—1 and 3, R. Woods. 2, J. Hawkins. *Hen*. H. Yardley. ANTWERPS.—Short-faced.—1, 2, 3, W. Moseley. *Hen*. H. Yardley. *Hen*. T. S. Kemp. Long-faced.—1, J. C. Waterhouse. 2 and 3, C. F. Herrieh. *Hen*. S. Wade. ANY OTHER VARIETY.—1 and 3, J. C. Waterhouse. 2, H. Yardley. *Hen*. R. Woods. SELLING CLASS.—1, J. C. Waterhouse. 2 and 3, R. Woods. *Hen*. T. S. Kemp. LOCAL CLASS.—1, 2, and 3, M. & A. Weston. *Hen*. R. Adams.

CAGE BIRDS (LOCAL DEPARTMENT).—BELGIANS.—1, S. Bunting. NORWICH.—Clear Yellow.—1, W. Ashley. 2, H. Watson. 3, J. Lowe. *Hen*. H. Ball. Clear Buff.—1, W. Ashley. 2, E. Fox. 3, H. Watson. *Hen*. C. Dakin. Lightly-marked Yellow.—1, H. Watson. 2, W. Ashley. 3, J. Lowe. *Hen*. H. Ingham. Lightly-marked Buff.—1, W. Ashley. 2, H. Watson. 3, J. Lowe. *Hen*. H. Ingham. Evenly-marked Yellow.—1, C. H. Legge. Evenly-marked Buff.—1, S. Bunting. 2, W. Ashley. 3, E. Merrin. *Hen*. J. Lowe. Heavily-marked Yellow.—1 and 3, J. Bexson. 2, C. Dakin. *Hen*. W. Ashley. Heavily-marked Buff.—1, H. Watson. 2, J. Lowe. 3, W. Ashley. *Hen*. E. Merrin. Clear or Lightly-marked Yellow, not Cayenne-fed.—1, J. Lowe. 2, J. Bexson. Clear or Lightly-marked Buff, not Cayenne-fed.—1, E. Ward. 2, J. Bexson. 3, H. Legge. *Hen*. J. Lowe. Green Jouque.—1, W. Ashley. 2, H. Watson. 3, C. H. Legge. Green Beady.—1, W. Ashley. 2, C. Dakin. 3, J. Lowe. Evenly-marked Crested Buff.—1, J. & C. Torr. 2, C. H. Legge. Evenly-marked Crested Buff.—1, H. Watson. 2, W. Ashley. 3, J. & C. Torr. *Hen*. C. H. Legge. Unevenly-marked and Variegated Crested Buff.—1, H. Watson. 2, C. Dakin. 3, J. Bexson. Crested, Clear Body.—1, J. & C. Torr. 2, W. Ashley. 3, H. Watson. *Hen*. C. Dakin. LANCASHIRE COPPY.—Yellow.—1, W. Ashley. Buff.—1, W.

Ashley. LIZARD.—Golden-spangled.—1, W. Ashley. 2, W. Scanlan. 3, S. Bunting. *Hen*. W. Woodard. Silver-spangled.—1, S. Bunting. 2, W. Scanlan. 3, C. Dakin. *Hen*. C. Legge. Golden-spangled, Broken Cap.—1, W. Ashley. 2, W. Scanlan. 3, S. Bunting. Silver-spangled Broken Cap.—1, W. Ashley. 2, W. Scanlan. 3, C. Dakin. *Hen*. S. Bunting. CINNAMON.—Self Jouque.—1, W. Ashley. 2, H. Ball. 3, J. Lowe. *Hen*. W. Woodard. Self Mealy.—1, W. Ashley. 2, H. Ball. 3, E. Fox. *Hen*. J. Bexson. Variegated Jouque.—1, J. Bexson. Variegated Mealy.—1, J. Bexson. 2, S. Bunting. MULES.—Dark Jouque Gold-finch.—1 and 2, J. Bexson. 3, S. Bunting. Dark Mealy Gold-finch.—1, J. Bexson. 2, W. Ashley. 3, H. Watson. *Hen*. S. Bunting. Light Jouque or Mealy Gold-finch.—1, S. Bunting. Any other variety.—1, J. Bryan. 2, E. Ward. 3, J. Bexson. The Special Prizes for most points were awarded to W. Ashley, H. Watson, John Bexson, S. Bunting, C. Legge, Joseph Bexson, W. Woodard, and E. Ward.

CAGE BIRDS (ALL-ENGLAND DEPARTMENT).—NORWICH.—Clear or Ticked Yellow.—1, C. J. Salt. 2 and 3, W. Pratt. *Hen*. G. Taylor. Clear or Ticked Buff.—1, W. Pratt. 2, J. C. Cleminson. 3, C. J. Salt. *Hen*. G. Taylor. Evenly-marked or Variegated Yellow.—1 and 2, C. J. Salt. Evenly-marked or Variegated Buff.—1, and 2, C. J. Salt. 3, C. Hampton. *Hen*. G. Smithurst. CINNAMON.—Jouque.—1 and 2, C. J. Salt. 3, C. Hampton. Mealy.—1 and 2, C. J. Salt. 3, G. E. Russell. LIZARDS.—Golden-spangled, Clear or Broken Cap.—1, T. Cleminson. 2, S. Bunting. 3 and 4, J. Cleminson. Silver-spangled, Clear or Broken Cap.—1 and 3, T. Cleminson. 2, S. Bunting. *Hen*. J. Cleminson. NORWICH.—Crested Yellow.—1, S. J. Orme. 2, C. J. Salt. 3, W. Greaves. *Hen*. W. Clark. Crested Buff.—1, C. J. Salt. 2, F. Knaggs. 3, W. Clark. *Hen*. H. Watson. GOLDFINCH MULES.—1, C. J. Salt. 2, G. E. Russell. 3, T. Bealey. *Hen*. C. H. Legge. SELLING CLASS.—1 and 2, W. Pratt. 3, T. Cleminson. *Hen*. C. J. Salt. GOLDFINCH.—1, C. H. Legge. 2, Mrs. A. Utton. 3, H. Watson. *Hen*. J. Dowus. LINNET.—Brown.—1, S. Bunting. 2, T. Nettleship. 3, H. Watson. *Hen*. W. Holmes. ANY OTHER VARIETY OF BRITISH BIRDS.—1, T. Newbold. 2, R. Adams. 3, Mrs. J. Fogg. *Hen*. W. Burniston. PARROTS, OR ANY VARIETY OF LARGE FOREIGN BIRDS.—1, 2, and 3, J. A. Barrs. *Hen*. J. Kington. ANY VARIETY OF SMALL FOREIGN BIRDS.—1 and 3, J. A. Barrs. 2 and 4, W. Bunting.

RABBITS.—LOP-EARED.—1 and 3, C. E. Thompson. 2, H. Ball. *Hen*. T. C. Bails. ANY OTHER VARIETY.—1, E. Robinson. 2 and Special, W. H. Horner. 3 and 4, E. Pepper. SELLING CLASS.—1, E. Pepper. 2, A. Trussell. 3, O. Andrews. *Hen*. H. Ball.

JUDGES.—Poultry: Mr. E. Hewitt, Birmingham. Pigeons: Mr. Hawley, Bradford. Cage Birds: Mr. E. Bemrose, Derby; Mr. G. Cox, Northampton. Rabbits: Mr. G. A. Crewe, Etwell, Derby.

DUNDEE POULTRY SHOW.

THE first Exhibition of the Dundee Dog and Poultry Society was held on the 8th and 9th inst., and six hundred pens of poultry came forward. It is six years since a poultry show was held here, but as it resulted in a heavy loss the experiment was not repeated. The uniting of the canine and feathered tribes in one exhibition seemed to draw an immense number of visitors on this occasion, and we expect the result will be a financial success, and that the Exhibition will be an annual one in future.

The poultry opened with *Scotch Greys*. In cocks first to a capital Coloured one, his sickles not full grown. Hens very good, especially the prizewinners. *Dorkings*.—First a very good coloured cock, second and third Silver-Greys; both promising birds. Pen 26 (Admiral Dougall) a good Silver-Grey, but still in moult. Hens.—First and second Coloured, and third Silver-Grey. *Brahmas*.—The winners all good, third being light, the others dark. Pen 60 (Duncan) a good one. Hens.—The judging here not so satisfactory; first a hen of small size, dark, as was second; third light. Pens 71 (Dempster) and 73 (Sandeman) might have changed places with some of the winners. *Cochins*.—Only five cocks entered. First Buff, second Partridge, third White; all good. In hens the winners all Buff; 96 (Davidson), as good as any, even allowing for her faint colour. *Game*.—Black Red cocks a large class of twenty-six, the competition very keen, the winner turning up in a Forfar bird. Brown Red cocks fewer in number, the winner also from Forfar. Black or Brown Red hens.—The winner a stylish Brown Red from Carlisle, second same colour, third Black Red, both from Forfar, where there are many breeders of Game fowls. Other Game cocks.—First and second grand Piles, still from Forfar; third a good Coloured Duckling from Fife. Hens.—First a Pile, second a good Duckling. Game fowls numbered nearly a hundred pens. *Game Bantams*.—The awards were not posted when we made our notes, so cannot criticise them. Other Bantams.—First and second to Silver-laced, the latter dull in lacing; third Blacks. Silver-laced seem to be putting the Golds out, which is a mistake, as both are equally pretty. Not a pen of Golds in the Show. *Hamburgs* (Spangled cocks).—First an easy win, a splendid Silver cock; second a Golden. Many of the Golds too dark for show. Hens.—Silver first, Gold second; both very good. Pencilled cocks.—Winners all Golden. Hens.—First and third Golden, and being entered cheap were soon claimed; second Silver. *Spanish* only six pens, but first very first-rate. *Leghorns*.—A capital White with fine pure earlobes won; second, White; and third Brown. In the hens the winners were respectively of the same colours. Many were very small, and we think the breed is not gaining ground in Scotland. Any other variety.—All Polands, except a pen of small Sultans. Very good Gold Polands first. Four classes for Dorkings, Cochins, Brahmans, and Any other variety, cockerel and pullet in each pen, brought nearly one hundred entries, and paid prizes twice over in entry fees. In *Turkeys*, *Geese*, and *Ducks* the exhibits were about as usual.

POULTRY.—SCOTCH GREY.—Cock.—1, T. Fullerton. 2, Clarkson & Hamilton. 3, A. Reid. *Hen*—1, Mrs. J. A. Dawson. 2, Clarkson & Hamilton. 3, A. Reid. DORKINGS.—Cock.—1 and Cup, J. Turnbull. 2, T. Williamson. 3, D. Laird. *Hen*. J. Smart. *Hen*—1, G. S. Robb. 2, J. Anderson. 3, T. Williamson. *Hen*. Admiral M. Dougall. BRAHMAS.—Cock.—1, Cup, and 3, D. J. T. Gray. 2, Lonie & Sheret. *Hen*—1 and Cup, J. Sandeman. 2, H. Wilson. 3, W. Mitchell. COCHIN-CHINA.—Cock.—1 and 3, Mrs. W. Steven. 2, Miss E. Russell.

Hen—1, Cup, and Cup for best bird in Show, J. Wyse. 2 and *vhc*, A. Dry-rough. 3, Mrs. W. Steven. *GAME—Black Red—Cock*—1 and Cup, C. Jamieson. 2, J. Richard. 3, D. W. Dacres. *Brown Red—Cock*—1, J. M. Beth. 2 and 3, W. Webster. *Black or Brown Red—Hens*—1, J. Brough. 2, J. M. Beth. 3, A. & D. Reid. *vhc*, C. Jamieson. *Any other variety—Cock*—1, Dall & Pygott. 2, D. & C. Blair. 3, J. Hall. *vhc*, C. Kinner, jun. *Hen*—1, Forbes & Petrie. 2, Gray & Stephen. 3, D. Addie. *vhc*, J. Black, A. Catto, J. Patullo. *GAME BANTAMS—Black or Brown Red—Cock*—1 and Cup, Duncan & Kennedy. 2, D. Laing. 3, T. H. & A. Stretch. *vhc*, W. Milne, D. Laing. *Hen*—1, W. Horne. 2, R. Brownlie. 3, W. Foster. *Any other variety—Cock*—1, R. Brownlie. 2, J. R. Kilgour. 3, J. Summers. *Hen*—1, J. Dargie, jun. 2, J. D. Donald, jun. 3, P. McLean. *BANTAMS—Any other variety*—1, W. B. Turnbull. 2, J. A. Dempster. 3, W. Webster. *vhc*, Miss R. C. Frew. *HAMBURGS—Gold or Silver-spangled—Cock*—1, J. M. Campbell. 2, T. Tweedy. 3, J. Gilmour. *vhc*, W. Chalmers. *Hen*—1, J. M. Campbell. 2, J. Roberts. 3, J. & R. Ogg. *Gold or Silver-pencilled—Cock*—1 and Cup, W. Barnes. 2, J. Brand. 3, G. Anderson. *vhc*, W. Barbour. *Hen*—1 and 2, D. Ruthven. 3, W. Barbour. *vhc*, J. Brand. *Cock*—1, A. Williamson, jun. 2 and 3, T. Gilroy. *SPANISH—MI-NORCA AND ANDALUSIAN*—1, J. Norval. 2, J. Wishart. 3, J. Mill. *LEG-HORN—Cock*—1, Mrs. Spence. 2, Dr. A. R. Ritchie. 3, J. Masterton. *Hen*—1 and 2, J. Masterton. 3, Dr. A. R. Ritchie. *FRENCH FOWLS—1 and Cup, J. Masterton. 2, Mrs. W. Davidson. 3, J. M. Stanger. ANY OTHER VARIETY EXCEPT BANTAMS*—1, J. Taylor. 2, S. W. Wildham. 3, D. Marr. *SELLING CLASS*—*Cock*—1, J. & C. Sneddon. 2, R. Topsis. 3, J. Banks. *vhc*, Admiral M. Dougall. *Hen*—1, J. Wyse. 2, J. Masterton. 3 and *vhc*, J. D. T. Gray. *CHICKENS—Dorkings*—1, W. Snowie. 2, J. Rutherford. 3, D. Sime. *vhc*, J. T. Cathcart, Mrs. J. Sinclair. *Cochins*—1, Cup, and Cup for best pair in Show, Mrs. W. Steven. 2, J. Wyse. 3, T. Fullarton. *vhc*, J. O. Rice, Mrs. A. Lee. *Brahmas*—1, W. Sandeman. 2, Miss E. Russell. 3, J. & W. Birch. *vhc*, J. Thomson, W. Mitchell. *Any other variety*—1, J. Thomson. 2, W. Webster. 3, W. Henderson. *Game*—1, J. & W. Birch. 2, Mrs. H. M. Alexander. 3, J. Menzies. *DUCKS—Rouen*—1, J. Adam. 2, H. B. Marshall. 3, Admiral M. Dougall. *Aylesbury*—1 and Cup, Mrs. T. Lawson. 2, A. Mitchell. 3, J. Adam. *vhc*, J. J. Gunn. *Any other variety*—1, Mrs. A. G. Duncan. 2, Master C. L. Ralston. 3, J. Taylor.

Mr. J. H. Smith judged the Game and Game Bantams, and Mr. Raines of Stirling the rest.

CAMBRIDGESHIRE ORNITHOLOGICAL SOCIETY'S SHOW OF POULTRY, &c.

THE Society's Show of Poultry, Pigeons, Cage Birds, and Rabbits was held in the new Corn Exchange on November 6th and 7th, when the following prizes were awarded:—

JUDGES—Poultry and Pigeons: Mr. W. B. Tegetmeier. *Cage Birds:* Mr. W. A. Blakston. *Rabbits:* Mr. G. Johnson.

VARIETIES.

WE regret to hear that Mr. King, the Secretary of the Oxford Show since its foundation, will resign before another year. The poultry-fancying public is greatly indebted to him for the untiring energy which for seven years he has bestowed on the organisation of this now first-rate Show.

— A MEETING of fanciers has been held in Shrewsbury to

discuss the advisability of holding a poultry show there. It was decided that one on a large scale with a liberal prize list should be held on January 2nd and 3rd. The show will in all probability be under the Poultry Club rules, and with such enthusiastic and practical fanciers as the Rev. W. Serjeantson and Mr. A. Darby on the committee ought to be a great success.

— IN Mr. Bennett's letter (page 360) on the fertile worker the drones are said to have emerged after the "seventy-first day," instead of "twenty-one days" after the eggs were first noticed.

— "A PERTSHIRE BEE-KEEPER" writes:—"I have read with considerable interest the contributions of Mr. Pettigrew and the 'RENFREWSHIRE BEE-KEEPER' in your Journal, and am of opinion that thanks are due to the latter for his criticism of Mr. Pettigrew's mistakes in regard to the Stewarton boxes and system of management. Mr. Pettigrew seems to me like a man who is angry and consequently imagines that his opponent has become angry too. All who are personally acquainted with the 'RENFREWSHIRE BEE-KEEPER' know that he is rather good-natured and amiable than otherwise, and if Mr. Pettigrew carries out his intention to visit him I am persuaded he will receive a most hearty and kindly welcome, whether he is able to fulfil his offer to produce 'crude honey' or not."

— "A RENFREWSHIRE BEE-KEEPER" sends us the following note on an indication of a severe winter.—"Calling on an apiarian friend this week, resident in our county, I was struck at the extent to which propolis barricades were built at the entrances of his stocks of bees—a sure indication of a severe winter. Last autumn no such erections were raised. A mild winter followed. Our little favourites thereby showing their instinct in forecasting the weather."

TAKING HONEY AND WAX.

THE taking of both honey and wax is a most unpleasant and disagreeable operation. There is nothing in apiculture that I shrink from but the running of honey and wax from combs. Taking the honey from combs by any known process is unpleasant work, and melting the combs into wax is more unpleasant still. I therefore heartily sympathise with a correspondent, "C. R. S.," who says that he and many besides would be glad to have some hints on the best methods of taking honey and wax. Your correspondent has "the combs of forty hives and supers all clean and free from dead bees and grubs, but dreads the mess of boiling."

For forty years I have been wishful to find an easy way of doing this unpleasant work, and often have we suggested the desirability of inventing an instrument to press the honey from the combs. Instruments have been produced, but not one of them has been satisfactory. The American slinger answers for taking clover honey from combs in bar-frames, but it cannot sling heather honey from combs. But the process of taking honey by the slinger is disagreeable. The combs have to be handled and the lids shaved off the sealed combs before they are placed in the instrument, which casts out and mixes crude and perfect honey. For casting honey out of old tough combs it is in our opinion the best instrument yet invented. I can say neither more nor less in favour of the American slinger.

For us who keep straw hives and take therefrom run honey by the hundredweight, there has appeared no instrument equal to human hands. It is, as everybody knows, unpleasant work, but we make the best of it, and get it done as speedily as possible. By hand pressure we can take 50 lbs. of honey from combs in an hour or thereabouts. As soon as the bees are driven from their combs the hives are carried to a hothouse or near the kitchen fire, and there the cross sticks are withdrawn, the combs carefully taken out and divided. All the best honeycombs are placed in a milk pan, the second best placed in another milk pan, and the empty and brood combs are placed in a third pan or empty bee hive. All this is but the work of a few minutes; and before the combs have time to cool or lose their natural heat we seat ourselves beside the best combs and press the honey from them. But let it be understood that there is a right and wrong way of doing this work. First, one comb is lifted and broken into pieces about the size of a woman's hand. One by one these pieces are placed on edge between the fingers and thumbs of both hands, so that the pressure comes on the sides of the cells, causing the honey to flow rapidly into the pan. These pieces of comb are turned and doubled in the hand, if need be, for more pressure. Thus they become dry and hard, and are cast amongst the empty brood-combs. After all the combs are thus gone over and squeezed the honey is run through a bag of cheesecloth or strainer into a honey jar, and skimmed next day. Thus we have honey without a stain or speck of impurity.

The second pan with inferior combs—combs containing both honey and pollen—are treated in the same way, but with far more care and less pressure. The difficulty here is to keep the pollen from tainting the honey. Many cells half full of pollen are filled to their tops with honey, and many honey cells are found amongst pollen cells. We almost always succeed in taking the honey from

such cells without letting the taint or taste of pollen pass into the honey; and rather than risk danger in this direction we put aside the pollen combs with honey in them for feeding purposes. For quality we sacrifice quantity; and by this method of pressure we obtain more honey and better quality than is had by the cottager's plan of breaking all the combs with a knife and draining the honey through a cheesecloth, because the knife breaks the pollen, and this taints the honey. I hope that someone will invent a simple instrument to press the honey out instead of the hands. My inventive powers are but feeble, but I can see that two perforated boards fixed about 2 or 3 inches apart to receive honeycombs edgewise, with some lever like a pump handle to come down between them, would be much better in every way, and do four times more work than human hands. Before I leave the process of honey-taking let me ask the reader to bear in mind that the honey should be drained from combs in their natural heat, and that, if allowed to cool, the honey does not run so well. It is rather difficult to impart artificial heat to honeycombs. In doing this before a fire the combs are apt to melt.

I do not know how foreign honey is taken from combs, but much of what comes to England is well and cleanly taken. I have seen barrels of pure Chilean honey on sale in Manchester without any impurity or taint whatever.

The lady at our house is wonderfully clever in the work of melting wax. All the loose, empty, offal combs are closely pressed together in big lumps and cast into a large bag of cheesecloth. When this bag is full its mouth is closely tied and cast into a copper or boiler of clean water. When it boils, the wax—a beautiful yellow oil—swims on the top. This oil is skimmed off and run through a strainer or muslin cloth into a pan with some clean cold water in it. When all the oil is thus skimmed off, the copper is emptied and washed. The wax is boiled a second time in clean water and put through the strainer. This finishes the work of wax-melting. The wax should not be cooled rapidly, otherwise the cakes would crack on their surface. As wax is very inflammable, containing as it does more than 80 per cent. of carbon, great care should be used in boiling it not to let it tip over the copper into the fire. As wax sticks to everything it touches, plenty of soda should be used in cleaning dishes, &c., used in making it. Honey is an excellent soap in cold water, but forms a greasy mess in warm water. Nothing but pure cold water should be used in cleaning anything touched by honey.—A. PETTIGREW.

STRAW SKEPS AT THE CRYSTAL PALACE SHOWS.

My attention has been directed to a statement of Mr. Pettigrew's in a late number of the Journal, that straw skeps were refused admission to the Crystal Palace bee shows, which your correspondent "A RENFREWSHIRE BEE-KEEPER" calls upon the Hon. Sec. to refute. As I held that office at both shows I say most emphatically that Mr. Pettigrew is wrong. I do not know whether he means full skeps or empty ones, but referring to the first catalogue I find there were four competitors for a prize for the latter class. Nine prizes were offered and competed for by filled straw supers alone, and twenty-nine prizes open to both wood and straw. So far from admission being refused to straw skeps, the many visitors to the Show must remember that scores of such hives appeared on the tables, and at the second Crystal Palace Show they were also well represented. I can hardly understand how Mr. Pettigrew could make this mistake, seeing that I myself sent him the prize schedules and invited him to judge the exhibits.

I have also another grievance against Mr. Pettigrew. In the Journal, November 7th, in explaining the wrong measurements he had given of the Stewarton hive, he says he quoted from the description of the hive in my book, "A Manual of Bee-keeping." Rather astonished I refer to the book and find the true dimensions, 14 inches diameter, are there given, and not 15 inches as Mr. Pettigrew has stated. Surely Mr. Pettigrew should be a little more particular before shifting his own blunders on to my shoulders.—JOHN HUNTER, *Eaton Rise, Ealing.*

UNPRODUCTIVE EGGS.

THE fact that a correspondent of this Journal saw some eggs in combs which did not become brood or hatch into bees, does not in our opinion prove that they were blind or incapable of yielding bees. The eggs of a queen bee are unlike the unfertilised eggs of birds, which cannot be quickened into life. There are no blind eggs in a bee hive. With proper treatment they are productive. A fertilised queen lays both male and female eggs; an unfertilised queen produces male eggs only, and very few of them comparatively. These things are well known by our respected correspondent. It is believed that the female eggs only are fertilised in the body of the queen, and that the male eggs of a fertilised queen bee escape unfertilised. Though there are difficulties and mysteries surrounding the manner or question of egg-fertilisation, almost all advanced apiarists accept the theory as well established.

As to the eggs seen in the combs which did not produce bees,

there does not appear to be any difficulty in accounting for the fact if we admit that working bees have both the will and the power to remove eggs and destroy them when they do not want brood, and this destruction of eggs or prevention of brood-rearing is of very common occurrence. Egg-laying, or the production of eggs in queen bees, is involuntary so far as she is concerned. A queen can neither form nor hinder the formation of eggs, and when they are formed she cannot retain them. But the working bees can determine whether the eggs shall or shall not be quickened into life—whether they shall or shall not become perfect bees. Very often in the middle of summer, when queens are laying perhaps two thousand eggs a day, have we known the bees decline to set them, but hatched out the brood that was somewhat advanced. In times of unfavourable weather setting in, threatening the whole community with poverty and starvation, the bees wisely or instinctively decline to set eggs. We have known young swarms after building a few combs, and by reason of unfavourable weather were hindered from building more or gathering honey, decline to set eggs, and left their hives and combs, and went off as "hunger swarms" without an egg or speck of honey in them. In autumn, in the face of winter, bees are naturally disinclined to engage in the work of brood-rearing, but on being vigorously fed and kept warm this disinclination is removed to a certain extent and breeding recommences—not always, but oftentimes.—A. PETTIGREW.

REMARKS.

- 6th.—Little snow in morning; clear fine bright day; beautiful moonlight evening.
7th.—Windy in morning, but very clear sky; fine day throughout with bright sunshine; little misty towards evening; moonlight night.
8th.—Wet morning, hail shower 10.5 A.M., brighter with intervals of sunshine in middle of day; cold shower in afternoon; squall with heavy rain at 4.5 P.M.; high wind and rain in evening.
9th.—Clear frosty morning; very fine bright day; moonlight night.
10th.—Very squally with rain during the night; wet morning at 2.45 P.M., great squall of wind, with rain and sleet, windy and wet all day; at 9.30 P.M. fine and moonlight.
11th.—Clear bright morning, short shower of small hail at 1.35 P.M.; fine afternoon; showery in evening.
12th.—Clear fine morning; solar halo 2 P.M.; after 3 P.M. dull and rather misty; damp and cold evening.
Not quite so cold as last week, but still cool for the season.—G. J. SIMONS.

COVENT GARDEN MARKET.—NOVEMBER 13.

We have no alteration to quote from last week.

From observations taken near London during forty-three years, the average day temperature of the week is 46.5°; and its night temperature 33.8°.

From observations taken near London during forty-three years, the average day temperature of the week is 46.5°; and its night temperature 33.8°.

THE SEASON AND WORK.

FREQUENTLY we find reference made to the season and the crops, but not so frequently to the labour required for producing them. The labour, however, expended in gardens is not by any means limited to producing crops of flowers, fruit, and vegetables, for much time is necessarily occupied in keeping a garden neat, without which it cannot be enjoyable.

Usually the labour provided for the cultivation and keeping of private gardens is fixed in character: that is, a certain number of men are allowed, and to these no addition can be made let the season be what it may. Even in a favourable season it is not often that the labour staff is in excess of the requirements, and generally it is only by some scheming and diligent application that different kinds of work can be done at the right time; and I may add that it is only by doing work at the right time that a garden can be rendered to the fullest extent profitable and pleasurable. If, for example, plants cannot be potted when they require it, seeds sown, crops planted, lawns mown, and weeds destroyed, the gardener works at a great disadvantage, and the condition of the garden under his charge can no more satisfy him than it can the owner of it. But while a gardener knows well the reason of the shortcomings it cannot be expected that an owner can at all times so fully appreciate them: hence as a matter of simple justice to all, to employer as well as employed, I venture to allude to the subject now.

The summer which has just terminated has been emphatically a season of hard work for all engaged in the management of gardens. Where adequate assistance has been afforded it has been a summer of plenty as regards vegetables—plenty, I mean, combined with neatness; but where no extra labour has been provided it has been utterly impossible to keep gardens as clean as usual and at the same time maintaining the necessary supply of floral and culinary products.

Under these circumstances it is not surprising that some dissatisfaction has been expressed by employers, and which in more than one instance, to my knowledge, has resulted in changes of gardeners. Possibly if a clear temperate explanation of the extraordinary nature of the season had been rendered the position would have been so far understood to have reduced the differences considerably, even to the extent of preventing the separation of a generally good man from a generally good master. But gardeners are not always capable of making an intelligible explanation of their position when surrounded by untoward circumstances; and employers, it must also be suggested, are not always in a listening mood. It becomes therefore necessary to discuss the subject in your columns where, as is fully admitted, the disposition is in many ways manifest that the governing principle is justice to all—a desire that masters should be satisfied and men contented.

I am not certain that I am capable of dealing with a subject that is in some degree delicate and complex in a

satisfactory manner; but I can at least approach it without prejudice, seeing that I have not been a sufferer by this work-producing season because extra assistance has been afforded to meet the extra work. I have further endeavoured to procure evidence that the season has really been what is termed an unusually heavy one, for gardeners especially, and cultivators of the soil generally. In order to obtain the best information possible I wrote to two nurserymen, two market gardeners, and two managers of public parks, inquiring if they had found it necessary to incur additional expenditure by increasing their labour staff in accordance with the incidences of the season. In every case the replies were in the affirmative. One of the nurserymen wrote that he had found it imperative to employ twenty-five men in addition to the usual staff to “keep the place in anything like order.” A market gardener replied that two extra men per acre were barely sufficient to “prevent the weeds eating the manure that was purchased for the crops;” and both the park managers assured me that it was only by encouraging all the men to work overtime to the extent of three hours a day that the lawns could be kept decent, grass edges clipped, and walks clean. In the matter of mowing, one of the managers stated that quite double the amount of labour had been necessary that was requisite in an ordinary season, “for,” he observed, “while in some seasons we had only to cut the grass once in ten days or a fortnight, this year we have frequently had to mow the lawns twice a week; the labour account, therefore, must be increased.”

An unusually fine autumn followed the extraordinary work-producing summer, and arrears have in many instances been brought up, but the year will long be remembered by gardeners on account of the extra amount of labour it involved, and even then gardens and grounds could not be kept so neat as desired. It is fair to all, I think, that the evidence I have adduced of the real nature of the season be recorded.—A NORTHERN GARDENER.

HOW I GROW THE CYCLAMEN.

THE Cyclamen has so recently come to the front as an indispensable decorative plant that must be grown in quantity, that many who commence its cultivation are very often unsuccessful, with it though most desirous to succeed. I grow as many as I can find space for, and find it one of the most accommodating plants we have. Seedlings from seed sown in February of the present year are many of them coming freely into flower, some of the most precocious throwing flowers up as early as September. I find it necessary to raise a fresh supply of plants at least every second year, as those more than three years old are of no use for my purposes.

In February at latest we sow our seed. I find one of our Geranium boxes better than pots or small pans for sowing the seed in. The boxes are drained with coal ashes covered with a layer of moss, and then filled with a light but rich compost. The seeds are sprinkled evenly over the surface and merely pressed into the soil; a sheet of brown paper is laid over the surface of the soil for the double

purpose of excluding light and preserving to the seeds uniform moisture. At no stage of growth ought the soil to be dry, but at this, the most critical, attention should be given to keep the germinating seeds always moist. Placed in a temperature of 55° to 65° little time elapses before growth commences. The brown paper will be better dispensed with then, though the attention must not be relaxed. The plants will keep on adding one small leaf after another, the little bulb at the same time steadily increasing in size. By-and-by the plants will require transplanting, but do not be in too great haste over this. Use the same kind of boxes for pricking them off into, also the same kind of soil, only richer, and leave them awhile longer in the same structure. As natural warmth increases transfer them to a cold frame and keep them growing on there until about the middle of September, then pot them into 4-inch pots and keep them in a cool place until established. In the beginning of October transfer them to a structure where the temperature is kept warm enough for their progressing gently through the winter. Each plant will produce on an average two dozen of flowers. I use these as cut flowers, thereby saving larger plants from being in any way damaged in appearance.

About the end of May I have our stock planted out in a warm border in the kitchen garden, keeping the top of the bulbs slightly under the surface of the soil. If there is a necessity to water it is better to mulch the surrounding surfaces than to have to make continued applications of water, which always have a tendency to sour the soil. Until the time of lifting the plants, during the latter part of September, no further attention will be required more than keeping weeds down. The young plants are mostly all potted into 5-inch pots; the older plants, which are managed the same way during summer as these, are placed in pots 5 and 6 inches in diameter. The pots are drained with a few coal ashes, and a thin layer of moss is placed between these and the soil to keep the drainage clear. The soil used is composed of loam, a very slight addition of decayed manure, and a liberal quantity of sand. The soil is pressed firmly round the balls, the top of the bulb being kept on a level with the surface of the soil. The plants are then placed out of doors in a sheltered and shady position for two or three weeks to allow the roots to get hold of the soil, and are then placed in the same winter quarters as formerly. Some of the earliest varieties (they vary considerably in this respect) will be in flower at this season, and if more are wanted they are easily brought into bloom by placing as many as are required in a warmer structure.

With regard to watering, I like the soil kept in a moist condition; numbers of roots are pushed from the corms during winter, and inattention to watering is inimical to these. Where regular watering is neglected the foliage and flowers are apt to damp off at the junction of their stalks with the corm; this tendency is further increased by growing the plants in too low a temperature. By the time the plants are three years old many of the corms are too large for the sizes of the pots we grow them in, consequently there is a weeding-out of these every season after flowering. Those desirous of growing large plants would doubtless find these just at their best for that purpose; but as small decorative plants meet our requirements, as noted at the beginning of this paper, young seedling plants are what we rely on. The foliage, especially in a cut state, is here held in nearly as much estimation as the flowers. To the amateur with little time to spend over his greenhouse I know no other plant so easily grown and capable of giving as good returns during the winter and spring months as the Cyclamen.—R. P. BROTHERSTON, *Tynningham*.

ABOUT VINES.—No. 3.

UNDER the superintendence of Mr. Hunter I planted my first Vines on March 12th, 1876. Those along the front and back wall had their roots carefully spread out, and those along the centre, for supernumeraries, were turned out with the balls unbroken, the better to produce a few bunches that season. I particularly noticed that the latter made the stronger growth, notwithstanding their crop. A few days later I had my accident with the glass. Immediately after the wind we had snow and bad weather, and the men working on the border made it firm, which was undoubtedly beneficial to the Vines.

No fire heat was given until August, and this also I have since looked upon as an advantage. During May and June I was, twice in particular, twitted about the slow progress my Vines were making, and had friendly invitations to have others

planted. My Vines, unaided by fire heat, I grant made slow progress at first, but they have since proved that a slow start was not a disadvantage. By the end of the season they branched out and covered the roof. With the aid of fire heat, for young Vines at the right time, in the autumn I had them sufficiently ripened to carry a fair crop, and it was a day I am still proud of when with the first Grapes I ever grew I took first prize at our Newcastle Show amongst fourteen competitors.

During February this year I planted a second house, but only along the front and middle, as I have made the house half span to enable me to grow Peaches along the back, thus securing the Peaches light. The house is a plain wooden structure with two rows of posts for support, the second row being under the apex or 6 feet from the back. Having proved that the Alicante colours better and has a denser bloom on the back wall than when immediately under the glass, at every fourth post I have planted an Alicante, and I mean, with the exception of necessary openings, to run one rod the whole length about 4 feet 6 inches from the ground, that we may both see over the top from the path and get underneath when necessary. At this height these Vines will be no additional shade to the Peaches. Intending next spring to raise Cauliflower plants largely, as I did this, I do not intend having fire heat until after they are cleared out, then I intend to heat with flue and hot water combined. I have this autumn run a flue through my other house, and that I find is a great advantage. I do not intend to use the flue when starting the Vines, a damper being provided to turn the smoke either to the chimney or to the flue. I have dispensed altogether with early closing since July, the house from that time, as a rule, being open night and day. My canes have done fairly well, six or eight of them being 18 feet long, and I counted in one fifty joints. On the 6th of June I planted out several Vines of my own raising this year, and I see one (Ainwick Seedling) is now 17 feet long with forty-eight joints. They have also branched out in the most robust manner, but during these last six weeks I have taken all the laterals off. In this house the Peaches have ripened off admirably, and have produced clusters of fruit buds, and the bottom leaves of the Vines are now beginning to fall. It may interest some to know somewhat of a freak I played with a Duke of Buccleuch. Being disappointed of a Vine promised, and yet being determined in some form to try to grow this noble Grape, I planted a stunted cane I already had on the 6th of June. I had previously been kind to it, but with little satisfaction. After being planted it continued for a short while to make joints from an inch to 1½ inch long. Having some healthy young canes of Waltham Cross I planted one by its side and inarched it. Some three weeks or so after the Duke gave evidence of fresh life the two had become united, and it has since made a fine fresh growth of rather over 2 feet. When I commenced Vine-growing I had an impression that plenty of liquor of moderate strength was the best treatment. Now my firm conviction is, if you have good turf to grow in the less liquid manure a young Vine has the better. In my second house this season I have watered only with pure water. In my next your readers shall have some account of the trials, disappointments, and perplexities of an amateur.—JOSEPH WITHERSPOON, *Chester-le-Street*.

ROSE OLLA PODRIDA.

OTHER than the election the rosy talk in our Journal has of late been copious as to blooms, with here and there just a suspicion of thorn. With much I have been amused. For instance, we have had suggestions for an election from "ONE OF THE MILLION," endorsed by our friend Mr. Radclyffe, for 1, freest bloomers; 2, hardest; 3, best for bouquets; Mr. Radclyffe adding 4, best for scent; 5, best in bud for button holes. Then comes the privately sent suggestion from "A. C." as to the best Roses for travelling, and then Rev. C. P. Peach's idea for the newer Rose election, but confining the electors to six nurserymen selected by amateurs, and *vice versa*. And in the same number comes my friend Mr. Beachey with his classification. Now to the latter gentleman we owe a most interesting paper as to certain rules for deciding the best Roses for general purposes. This paper was published in the Journal some five years ago; it singled out nine points, I think, in Roses, and each point as highest value had the mark 3. He made out his return by this list, and, tried by this test, Gloire de Dijon, I recollect, came out as his best Rose. For general purposes this is a very good plan, but I ask my valued friend how many returns would he obtain made in this way? In these

high-pressure days men have not the time to devote to them, and the replies would be almost nil. Then if you take one point as suggested by "ONE OF THE MILLION," you would require an election for each separate point, and heartily sick most persons would be of the affair. Elections (Rose) "come but once a year," but unlike Christmas they do not always bring good cheer. Even once a year it occasionally brings snubs and growls; what would it do if I attached so many points as to give each elector an idea that he was in for a competitive examination? Now to our good friend Rev. C. P. Peach's idea. We should have three elections. First we should have an election for the six amateurs and then another for the six nurserymen, and by the time we got to the Roses both the selected would be tired of the whole affair, and the waste-paper basket or the next pipe or cigar being fired would be the end of the voting paper. It really is not so much, What is best to be done? as, How much can you get others to assist you in doing?

For a season or two we can afford to let general exhibition varieties alone, and we may, as I have said, take up the matter in a more restricted form; but before I pass on I would just remark on Class 2 of Mr. Beachey's—"The freest bloomers irrespective of the quality of the blooms." This class, he says, is altogether "cut out in the present election." Now I should say that Gloire de Dijon and Maréchal Niel, and probably Souvenir d'un Ami and with me Pierre Notting, were still in this class—certainly the former. Here I would remark how thoroughly I agree with Rev. C. P. Peach about this Rose. I contend it never has fair play as an exhibition variety, and, like everything else, if it be not cared for the success is doubtful. I heartily endorse every word he says about dear old Gloire—"Glory Die John," as old Tommy Coles of Wellow Rosery used to call it, but it is a Rose that will never die however cold the frosts of exhibition elections: it has too many good sound qualities. Considering how separated Rev. C. P. Peach and I are, and I should imagine different in soil and climate, it surprises me how nearly our experience seems to tally. I have already in the election cast a sort of doubt on Duchesse de Vallombrosa. I greatly fear she will prove to be a fine-weather lady, and I shall not be surprised to see her lower down three years hence. With Mr. Peach, too, I believe Marie Baumann to be the most exquisite Rose there is. On the plant, I prefer the pendant position; and what a thrill of delight comes over one as you lift the glorious bloom and so unfold its beauties to the eye. Grown on the seedling Briar, too, it has with me plenty of vigour, throwing up shoots 3 feet in length and nearly half an inch in diameter.

A different matter on which I again most thoroughly agree with Mr. Peach is the Manetti. I venture to say that if I had time to prepare the cuttings myself not one in a hundred—I had almost written thousand—should send up a so-called sucker—really a bud that has escaped the knife. Only on one or two occasions have I ever had a genuine sucker—that is a growth from the root, and that has been feeble. But then, on the other hand, I have had Manetti stocks from nurserymen, have gone over them before planting—not so easy whilst the stems are dirty, and overlooked buds, and then have had such a forest of Manetti in my bed as to make me give up the idea of budding them altogether; and then people say, naturally enough, that the Manetti does throw up suckers. The fault is not in the Manetti, but in the knifeholder, who neglects his work or slurs it over. To the beginner who would bud his own it is one of the most useful and easiest stocks to work; for—I say it advisedly—good as is the seedling Briar for growth, &c., it is a difficult customer to bud, and, as my experience goes, far more buds die on it from the knotty character of the stem than do on the Manetti: that is at least my experience.

Equally with Mr. Peach am I surprised that at least ten or fifteen (Mr. Peach says twenty) Roses are not named by everyone in naming forty-eight. It is a mystery to me, and I mutter to myself, *Tot homines*, or its English version of Apples and Onions. We do not all think alike, and some of us, I suppose, are woefully unfortunate and never get a Rose in its true character. As to Capitaine Christy, this has been a season for him, I fancy. I never saw it beautiful till this year, when I have cut several; but on a small plant in our cottage hospital garden I saw three splendid blooms out at the same time. Looking at them, carrying them in my mind's eye, and recollecting how a beautiful flower fixes itself on the memory, I should not be surprised at any person placing it in the second twelve, but in an unfavourable season I fear it will come ragged and coarse. Talking of Roses making a lasting im-

pression, I can picture some that many years have not effaced: and for years in my household, whenever Roses are the topic before strangers as to beauty of blooms, one of my daughters is sure to exclaim. "Ah! I never saw such a Rose as that Niphetos at our Rose show." This was some six years ago, and the exhibitor "WYLD SAVAGE." Well, yes, it *was* a Rose!

Once again I entirely coincide with Mr. Peach that "the only thing admissible in preparing blooms for exhibition is to remove a damaged petal." I do not quite like even this admission.

With Mr. Beachey I agree that exhibiting Roses is not *the* great pleasure in having them. I like them in the garden, in the house, and to send out to those who have none. This last is certainly my greatest delight connected with Roses. I feast my sight on them first, retain perhaps some of the best. One season I dressed a stand of eighteen daily in my hall, and directly after my breakfast I dispatch through the season from one to half a dozen baskets into the town.

Two curious things happened to me this season—nearly all my dwarf plants of La France died in the course of the summer; and nearly all the Marie Radys, after making good growth, suddenly turned yellow in foliage as they were coming to bloom, and, the leaves dropping, they looked like following suit, but they appear to have perfectly recovered. They did the same in a friend's garden.

Once again, even though it has been an exhibition election, yet judged by garden tests the large proportion of the seventy-two are not robbers; and after having learned to love the exquisite form of a good exhibition Rose, the flatness of many of the garden varieties does not contrast favourably, and, like matured taste in fruit, you prefer one in perfection to numbers that are sour or past their prime.—J. HINTON, *Warminster*.

FORCING VEGETABLES.

RHUBARB.

ALTHOUGH Rhubarb can hardly be considered a vegetable it is an article much grown in the kitchen garden, used in the kitchen, and forced throughout the winter season of the year. Where Apples are scarce Rhubarb is a good substitute for them. And for many purposes it is very useful. One great point in its favour is that it is easily forced, and those who care to do so may have a supply all the year round.

When forcing is begun at this time, or before the new year, the best way is to lift the roots and force them out of the ground. After the new year the roots throw up growths freely without being removed. When the roots are lifted any long ends may be cut off, so as to get them into small compass. Only roots with well-matured crowns should be selected thus early, and the finer the previous produce has been, and the wider the roots have been growing apart, the better will the crowns be ripened and the more readily will they force.

There are two ways of forcing Rhubarb—one in light and the other in darkness. Unless the heat is very strong, in the former case the stalks do not always grow freely, and are not tender, but in the dark it always grows quickly with sufficient heat and extremely tender. We have sometimes forced it in the bed of a Melon pit in full light, but we prefer it in the dark, and generally force it in the Mushroom house referred to in our notes on Seakale forcing. A good hotbed about 2½ feet thick is made, and the roots are packed close together on the top of it. The space between the roots is filled up with some old soil from the potting shed, and the whole is covered over so as just to leave the crowns above the soil. They are then watered with tepid water, and the hotbed and darkness soon do their work. We do not study to have any set heat at either top or bottom, only the latter should be the strongest, and the former will do well if it is between 60° and 70°. With good roots and ordinary attention the first dish may be gathered three weeks after the roots have been placed in heat. A few roots will give several dishes for some weeks in succession, and a few placed in heat every two or three weeks will keep up a constant supply. It may also be forced well above any boiler or fire provided it is covered well over with soil and kept constantly moist. When such places are not in the dark it is well to place a box over the young shoots as soon as they appear. If a hotbed is made up anywhere in the open air, the roots put in as recommended in the Mushroom house, covered over with a glass light or wooden shutter, and kept dark, will soon yield stalks plentifully.

In forcing it in the open air in spring it is only necessary to

place some old barrels, boxes, large drain tiles, or flower pots over the crowns and cover the whole with a good quantity of hot dung and old leaves. Care should be taken when the coverings are finally removed that the plants do not receive a severe check, or it may injure them for some years. When the roots are lifted to force we seldom plant them again, as a new stock of fine plants can always be secured by dividing old roots in spring and planting them out in good soil.—A KITCHEN GARDENER.

DRESSING CARNATIONS.

HAVING been an exhibitor for many years of various kinds of flowers I may perhaps be allowed to make a few remarks on the above subject. Is it right for an exhibitor to dress his Carnations or other flowers for exhibition? My own opinion is decidedly "yes," provided that first there is no rule of the society infringed in so doing; and secondly, that the dressing consists merely of the removal of a blemish or the skilful arrangement of the petals of the flower, so as to show it to the best advantage.

"D," and also my friend "WYLD SAVAGE" object. They say first that dressing is unnatural and artificial, and second that it gives one exhibitor an undue advantage over another. As to the first objection, that it is "unnatural and artificial," is not the production of a show flower from beginning to end artificial, and in one sense unnatural? Whoever yet expected to cut a show Rose by leaving his bushes to take care of themselves? Are not budding, manuring, pruning, thinning out the shoots, disbudding, shading, supporting, and training all artificial? If the exhibitor may not arrange the petals of his flower to advantage, why may he arrange the branches of his plants? I have never yet heard "WYLD SAVAGE" or "D," cry out against the marvellously trained pot Roses of Turner or Paul, and yet what would they be if every shoot, bud, and flower were not kept in place in an unnatural way by artificial means? They hold up their hands with horror because Mr. Douglas takes a few hours dressing his Carnations. Is there nothing to be said of those who spend not hours only but days, weeks, and years in the production of a specimen plant? If we must let Nature alone to arrange the petals of her flowers for show, would it not be equally reasonable to demand that she should be allowed to train herself into shape when plants are concerned? In fact the objection will not hold water.

A show flower is a flower grown by artificial means and shown by artificial means—a proof that Nature has been assisted and yet thwarted—a triumph of the gardener's art over the "WYLD SAVAGE" tendencies of Nature on the one hand, and a skilful taking advantage of its kindly efforts and capabilities on the other. As to the third objection—that it gives one exhibitor an undue advantage over another, and quite right too say I. Is a man not to reap the fruit of his skill? He has assisted Nature and overcome Nature in the growth of his flower. Why not let him alone to assist her in the perfect arrangement of the petals and to obliterate the trace of the thorny and thistly side of Nature, which exists more or less in all her productions, even in a blossom? If he can do this by honest and legitimate means well and good; he deserves to win. But—and here comes the pinch—let him, say I, do it himself. The show bench is, it seems to me, a test of individual skill, and it is no more fair for the exhibitor to import external aid in dressing his flowers than it is to import flowers from a neighbour's garden or to gum the petals of one flower into another.

Mr. Douglas says that the system of florists helping one another tends to promote good fellowship. Well, that may be so in cases where they are well known to each other and the skill of the opponents is nearly equal. I can quite understand Mr. Douglas and Mr. Simonite lending each other a helping hand, but one must not forget that there are often aspirants to fame cropping up at the shows who labour under the disadvantage of not knowing their fellow exhibitors, and under the still greater disadvantage of unskilfulness in the usual artifices of the florist. Such naturally feel aggrieved. An element is introduced into the competition for which they were not prepared. They find out to their dismay that it is one thing to be able to grow a good flower and another thing to be able to show it. They have patiently acquired sufficient knowledge for the first, but are all at sea when it comes to the second. Is it to be wondered at that when they see two or three skilled dressers engaged in transforming a stand of flowers into show

trim and are unable to do it themselves or to obtain help, that they feel that an unfair advantage is being gained over them? This being so allow me to suggest a remedy. Let there be a rule inserted in the schedules of the various societies that exhibitors or their gardeners must dress and set up their own flowers without assistance, and that any infringement of this regulation will disqualify.

Finally, that Mr. Rudd once showed a Carnation which did not need dressing and won is no proof that the generality of Carnations do not need it. Almost all flowers need a little manipulation of some sort to show them off to the best advantage, and no one was more surprised than I to hear that "WYLD SAVAGE'S" Roses all grow with stiff backs, so that they do not need the artificial assistance of wires to aid them to hold their heads up, and petals so beautifully arranged that they can without exception be shown as cut from the tree.—R. W. BEACHEY.

I HAVE read attentively the various remarks in your Journal on dressing Carnations. As probably I am one of the oldest florists in England, being within a few weeks of eighty-one years old, and as I commenced growing florists' flowers in 1812, I have witnessed the great improvement in all descriptions. My first essay was in Pinks, then Auriculas, Polyantheses, Tulips, Carnations, and Picotees. At one time I grew upwards of six thousand Tulips, a thousand Auriculas, upwards of a thousand Polyantheses, and in Carnations and Picotees upwards of five hundred pots, besides a large quantity in beds. In 1830 the Picotee was striped at the edges, and in a few years John's Prince Albert was raised, which became the original parent of all the fine sorts now grown. At that period Carnations and Picotees had to undergo the operation of dressing as well as Pinks and Auriculas. I well remember nearly sixty years ago I lost a first prize through my dresser cracking a petal in one of my Auriculas. I never knew a flower being staged without being operated upon: even Tulips had to submit to the pencilling in removing any dirt that might by flies have been soiled. I once wrote an article against cards being used to support the petals, but now I feel persuaded that the cards tend to improve the appearance of the blooms.—JOHN SLATER, *Late of Cheetham Hill, Manchester.*

GARDEN POTATOES.

It is well known that our best and most profitable Potatoes, although adapted for field culture on a large scale, are not as a rule the varieties to grow in rich garden soil, as their character for flavour and solidity generally becomes impaired at the cost of increased size. Bearing this in view a few years ago I consulted that eminent authority Mr. R. Fenn as to which was the best general-crop Potato for an amateur to grow in the rich old humus of a town garden; and acting on his somewhat qualified advice—for he honestly would not recommend thoroughly either the old Lapstone or his own handsome and high-quality Potato Rector of Woodstock for great productiveness—I tried these, and in addition upwards of one hundred other sorts without being able to obtain all I desired.

For flavour and appearance the Rector was unapproachable, and amongst the best of the others were the old Early Oxford, which when obtained true is short-topped, and although it comes in early, continues in use until April or May. It is also tolerably fertile and otherwise a good Potato, but it is almost impossible to obtain it true now.

Another excellent Potato, but coming into use somewhat later, is the Oxfordshire Kidney. It is of fine quality and a handsome and prolific sort, but in flavour it is not equal either to Lapstone or Rector of Woodstock.

I believe, however, now that the right Potato is forthcoming in Lady Godiva, raised by the Rev. Mr. Kittle of Birmingham, which seems to combine all the requisites for an amateur's garden and a gentleman's table, with fair size and productiveness. Through the kindness of Mr. R. Gilbert I have been enabled to see and taste it, and it is certainly a great advance upon the Lapstone in form and size. It is a handsome, pebble-shaped, equal-ended variety, skin smooth, and all the tubers appear even-sized; the flesh and flavour are of the same type and quite equal to the Lapstone, which I look upon as the *ne plus ultra* Potato for quality. Lady Godiva, too, will become one of our best show sorts, as it is free from deep and surplus eyes, and in appearance is all that can be desired. I trust I may be able to secure it next year for trial in the Experimental. It will admirably follow Myatt's Early Prolific *alias*

Royal Ashleaf, which is still by far the best early garden Potato.

For an amateur who depends upon his garden for his table supply of Potatoes the following will be a capital half-dozen to grow—viz., Walnut Leaf, and Early Handsworth (Messrs. Fisher & Holmes' stock) both dwarf sorts for frames; and Myatt's, Rector of Woodstock, Lady Godiva, Schoolmaster, and Oxfordshire Kidney for the open ground. I hear excellent accounts also of Woodstock Kidney, Beckenham Beauty, Trophy, and Beauty of Hebron; and if to these be added Snowflake and Sutton's Magnum Bonum—two invaluable and very fertile sorts—an excellent trial twelve will be found, and the trial will, I feel sure, combine some pleasure with little disappointment.—T. LAXTON, *Bedford*.

LILY OF THE VALLEY.

THE detailed account from R. P. Brotherston at page 344 of your number for November 7th on Lily of the Valley, describes a good system of preparing the plants to produce flowers early and annually with much better returns from home-grown plants than from imported clumps. It is easier to have these lovely sweet flowers after the new year than before. Where the flowers are expected from the early part of November and onwards it is not the work of a season to prepare the plants. If forced early for two or three seasons, and the plants are encouraged to make an early growth under the influence of plenty of light, air, and warmth, and after growth is completed placed outside to mature their crowns, so that they can receive an early rest, they will then produce flowers in November if required. We find ours come best when plunged in strong bottom heat with their crowns covered, so that they are not exposed to the light. We have introduced imported plants into heat as soon as they have arrived, and they have remained dormant for six or eight months and then produced flowers. We pot ours in 6-inch pots, in which they give quantities of flowers for several seasons without repotting if liberally supplied with liquid manure while making their growth.—W. BARDNEY, *Norris Green, West Derby*.

ROYAL HORTICULTURAL SOCIETY.

NOVEMBER 19TH.

WE have to record a very full, gay, instructive, and interesting meeting. The Council-room was rendered brilliant by large groups of Chrysanthemums from Messrs. Veitch & Sons, Chelsea, and Turner, Slough, and excellent stands of cut blooms were also staged. Mr. Bull arranged an extremely attractive group of ornamental-foliaged plants and Orchids, Mr. Wills excellently coloured *Dracænas*, Mr. Smith, Ealing Dean Nursery, *Cyclamens*, and Mr. Cannell splendidly bloomed *Geraniums*. These with some fruit were in the Council-room, and the vestibule was filled with fine collections of fruit and vegetables, groups of flowers, and a wonderful collection of Conifers and winter bedding plants from Messrs. Veitch's, Coombe Wood Nursery.

FRUIT COMMITTEE.—Henry Webb, Esq., V.P., in the chair. Mr. Ross, gardener to Charles Eyre, Esq., Welford Park, Newbury, sent nine Smooth-leaved Cayenne Pines. They were fine specimens of culture, but had unfortunately been kept too long, having become discoloured and spongy. A vote of thanks was awarded. Mr. Muir, The Gardens, Margam Park, Taibach, sent a Smooth-leaved Cayenne Pine. It had been grown in 20° less fire heat than is usually recommended for Pine culture, and the object in exhibiting it was to test its flavour grown under these circumstances. The flavour was excellent, yet the fruit being cold it was not so fully developed as it would otherwise have been. It was brisly acid and rather deficient in sweetness. Mr. Hunter, The Gardens, Lambton Castle, sent a seedling Pine Apple raised from seed of the Queen fertilised with the Smooth-leaved Cayenne. It is a large handsome Pine much resembling the Queen, and weighs 5½ lbs. The fruit had been ripe for six weeks, and had begun to decay. It was the first fruit that had been produced, and the Committee recommended that it should be seen again before giving an opinion. Mr. Charles Howe, The Gardens, Benham Park, Newbury, sent six well-finished bunches of Black Alicante Grapes, to which a cultural commendation was awarded. Mr. Joshua Atkins, gardener to Col. Loyd Lindsay, sent six very handsome bunches beautifully coloured of Muscat of Alexandria Grapes, to which a cultural commendation was awarded. Mr. Johnson, The Gardens, Bayham Abbey, sent three bunches of Mrs. Pince Grape, which were good but had begun to shrivel. Mr. Wood, gardener to Lady Augusta Mostyn, Leybourne Grange, Kent, sent fourteen handsome bunches of Gros Colman Grape. They were very large in the berries and remarkably well coloured. A cultural commendation was awarded. Mr. Harrison Weir, Weirleigh, Kent, sent bunches of Muscat Champion grown in a

ground viney. They were remarkably well grown, and a cultural commendation was awarded.

Mr. R. Gilbert, The Gardens, Burghley, sent a bunch of Trebiano, large and handsome. He also sent his new Melon Netted Victory, which was awarded a first-class certificate a short time ago. The fruit which was sent on the present occasion was, considering the late season, very highly flavoured, and maintained the high character it had received. He also exhibited a seedling Apple called The Student, which had passed its best, and the flavour had gone. It is a handsome good-looking Apple, and the Committee requested to see it in better condition before giving an opinion upon it. Mr. Plester, The Gardens, Elsenham Hall, Thetford, sent a seedling Apple not named, which is of a very promising character, and it was recommended to be shown again cooked at the next meeting. Messrs. J. & C. Lee & Son of Hammersmith sent a dish of Russian Transparent Apple, a good-sized Apple with a tender flesh like Calville Blanche. They also showed a seedling called Barnack Beauty, a small Reinette-shaped fruit highly coloured with a tender flesh, and of good flavour. The tree is said to be very productive.

Mr. J. Dobell, Island House, Loughborough, sent a dish of a seedling Apple which too much resembled Bess Pool to be considered distinct. Messrs. W. Paul & Son of Waltham Cross sent a seedling Apple called Waltham Cross, a very pretty roundish oblate and highly coloured fruit of good flavour. Messrs. Paul exhibited two others which did not possess great merit. Mr. Gilbert of Burghley sent, besides his other exhibits, a dish of Tomatoes, six Telegraph Cucumbers, Lettuce Selected Brown Cos, seedling Cucumber Dispatch, to which a letter of thanks was awarded. A seedling Potato called Lady Godiva (Kittoe), was of handsome form and good quality.

Mr. Ross, Welford Park, Newbury, sent a seedling Cucumber raised from Duke of Edinburgh crossed with Tender-and-True, but it was not considered an advance on existing varieties. Mr. Charles Frisby, The Gardens, Blankney Hall, Sleaford, sent a seedling Beet Frisby's Excelsior, of long narrow shape and good colour. Mr. R. Dean, Ealing, sent a dish of Vicar of Laleham Potato. Mr. George Donaldson, Keithball, Inverurie, sent a seedling Potato; and Mr. Ironside, Ingleston, Keithball, sent another seedling called Oliver Cromwell, both of which were to be tested at Chiswick. Two varieties of Turnip grown in the Chiswick Garden from seed received from Mr. W. Porter, Old Meldrum, N.B., were exhibited. They were received under the respective names of White Prize and Yellow Prize, and proved to be Snowball and Golden Ball. Mr. Sidney Ford, The Gardens, Leonardslee, Horsham, sent a dish of a seedling Apple called Dr. Hogg, very much resembling Calville Blanche in shape and colour, and with the delicate flesh of that variety. It was referred till next meeting, and was to be cooked when exhibited. Mr. Ford also exhibited a very fine collection of thirty-six dishes of Apples and a fine dish of Red Currants, to which a silver Knightian medal was awarded.

FLORAL COMMITTEE.—G. F. Wilson, Esq., F.R.S., in the chair. Taking the collections in the order of their arrangement we first arrived at a very large group of Chrysanthemums arranged by Messrs. James Veitch & Sons. The plants were grown in a natural manner—that is, they were not trained, nor had their buds been much thinned out. The group included all the best varieties in cultivation, and had an extremely gay appearance. A silver Banksian medal was recommended. Mr. Turner exhibited standard plants, models of their kind, with heads resembling those of well-grown standard Roses, and remarkable for the short flowering branches, which needed no tying to render the heads compact. All the best old and new varieties were included, two especially fine being La Nymph, pink Japanese, and Sœur Melanie resembling a small Elaine, and very floriferous—a splendid group, for which a small gold Banksian medal was recommended. Mr. Turner also exhibited a collection of cut blooms of good quality. Mr. Smith, gardener to Miss Sullivan, Broom House, Fulham, exhibited a dozen plants of Chrysanthemums remarkable for the size of their blooms, especially those of Golden Queen and Empress of India. A small bronze Banksian medal was recommended. Messrs. Jackson & Son, Kingston-on-Thames, exhibited cut blooms of Japanese Chrysanthemums, for one of which—Mons. Crousse, coral red, compact, and good—a first-class certificate was awarded.

Mr. Wills's group of *Dracænas* included the finest of the Anerley varieties, and striking amongst them was a well-coloured plant of D. Goldieana. The group was margined with small plants of *Adiantum farleyense*. A silver medal was recommended. Mr. Wills also exhibited *Anthurium Gustavii*, with green roundish cordate leaves nearly 18 inches long and 15 wide, the surface containing prominent white radiating veins.

Mr. Bull's group was very rich, the Orchids comprising *Lælia marginata*, very fine; *Cattleya Skinneri*; the new and distinct *Dendrobium superbiens*, also D. bigibbum; *Calanthes* in variety; *Odontoglossum vexillarium rubrum* very fine, *Inseleyi leopardinum*, crispum, and *Forbesii*; *Oncidium varicosum* and *tigrinum*; *Cypripedium*, *Masdevallias* and *Sophranites*. The group also included small and highly attractive plants of *Sarracenia Drum-*

mondi, *Anthurium Dechardi*, *Lilium neilgherrense*, *Dracænas*, Palms, and Crotons. A second-class certificate was awarded to *Odontoglossum madrense*. It has white sepals with maroon blotches and a rich yellow lip. The flowers are about 1½ inch in diameter, and are highly perfumed. Mr. Bull also exhibited *Croton Dormanianus*, a distinct variety of the volutus type, but the leaves somewhat spatulate—a promising variety. A gold Banksian medal was recommended to be granted to Mr. Bull for his excellent group.

Mr. Rowley, gardener to W. H. Covington, Esq., Esam Lodge, Streatham Common, exhibited large plants of standard *Heliotropes*, which were shaken in transit, and was awarded a vote of thanks. A similar award was made to Mr. Smith for *Cyclamens*, which were very fresh and fine considering the earliness of the season. To one of them, *Mont Blanc*, white, large, well-formed flowers borne on footstalks a foot high, a first-class certificate was awarded.

A first-class certificate was awarded to Messrs. Veitch & Sons for *Calanthe Sedeni*, the result of a cross between *C. vestita* and *C. Veitchii*. It is a splendid addition to this valuable class, being much deeper in colour than *C. Veitchii*. The flowers are the largest and richest of all, being very deep rose suffused with magenta, and a richer throat margined with white. The colour increases in intensity with the age of the flowers. The spike is robust and gracefully arched. This will become a standard variety, and will be coveted by all growers. Messrs. Veitch also exhibited *Cypripedium Laurenceanum* with grand marbled foliage and a very large expanded flower, and another forming on the same spike. It is of the *C. barbatum* type, and was sent from Borneo by Mr. Burbidge.

Mr. Jacques, gardener to J. Perrin, Esq., was awarded a first-class certificate for *Odontoglossum Alexandræ* var. *Perrini*, the most distinct variety that has yet been exhibited, every flower being broadly margined with purplish lilac. It is both novel and attractive. Mr. Cannell exhibited wonderfully fine groups of *Geraniums* White and *Salmon Vesuvius* in 5 and 6-inch pots, each plant carrying six to eight fine trusses, the tops of the flowers not being more than 6 inches from the surface of the pots. Mr. Cannell also exhibited grand bunches of cut blooms of leading zonal varieties, and was worthily awarded a vote of thanks. Mr. Gilbert, The Gardens, Burghley, Stamford, exhibited cut flowers of double *Primulas*, one of which—*Lord Beaconsfield*, is very rich in colour, and all were fine. Some of them had been previously certificated, and the variety named would possibly have received the same honour had a plant of it been exhibited instead of cut flowers.

Messrs. Hooper & Co., Covent Garden, exhibited about fifty plants of *Begonia Frœbelli* raised from seed sown in the spring. The plants were in 5-inch pots, and had fine foliage and flowers—valuable and attractive. A silver medal was recommended. The same firm also exhibited good *Cyclamens* and cut blooms of *Chrysanthemums*. Mr. Atkins, gardener to Col. Loyd Lindsay, Lockinge, Wantage, also exhibited a stand of *Chrysanthemums*, the blooms being arranged on moss, and was awarded a vote of thanks.

Mr. A. Waterer exhibited *Conifers* and a bright golden *Holly*—*Ilex scotica*—to which a first-class certificate was awarded. Mr. C. Noble exhibited *Thujaopsis borealis aureo-variegata*, which has been previously certificated. It is a free-growing and valuable *Conifer*. Mr. Ford, gardener to W. E. Hubbard, Esq., *Leonardslee*, was awarded a vote of thanks for cut sprays and cones of *Conifers*. Messrs. Veitch's collection of winter bedding plants—*Conifers*, berried shrubs, dwarf evergreens, &c.—was exhibited in a hundred flat baskets each 4 feet in diameter. The plants could not number less than two thousand, and probably much exceeded that number. It was altogether a remarkable contribution, and a gold Banksian medal was recommended to Messrs. Veitch. Sir C. W. Strickland, Bart., exhibited a flowering plant of *Coburgia trichroma*, for which a cultural commendation was awarded. A botanical certificate was awarded to Mr. Green, gardener to Sir G. Macleay, Bart., for *Hoplophytum calyculatum*, and a vote of thanks to Mr. Noble for *Crimson Bedder Rose* as a late-blooming variety.

Abutilon igneum with pendant crimson flowers, *Begonia Moonlight* very fine, and cut flowers of *Bouvardias* in upwards of a dozen varieties, were sent from the Society's gardens at Chiswick. The meeting was an excellent one, and there was a large attendance of visitors.

SPECIAL PRIZES.—The prizes offered by Messrs. James Carter and Co., Messrs. Sutton & Sons, and Messrs. Hooper & Co. were competed for at this meeting. For Messrs. Carter's prizes for a collection of ten dishes of vegetables, the kinds being stipulated but not the varieties, there were thirteen competitors. Mr. Pragnell, The Gardens, Sherborne Castle, received the premier position with splendid dishes of Improved White Spanish Onion, Schoolmaster and Magnum Bonum Potatoes, Williams' Matchless Celery, James's Intermediate Carrot, Veitch's Autumn Giant Cauliflower, Early Snowball Turnip, Carter's Heartwell Marrow Cabbage, Carter's Maltese Parsnip, and Pragnell's Exhibition Beet. Mr. G. T. Miles, Wycombe Abbey, was an excellent

second; Mr. G. Neal, gardener to T. Southby, Esq., Bampton, Oxon, third; and Mr. J. Baker, Broad Street, Bampton, Oxon, fourth.

Mr. Pragnell also won the first position in competition for Messrs. Sutton's prizes for a collection of vegetables with Early Snowball Turnip, Suttons' Improved Reading Onion, Tender-and-True Cucumber, Fulham Prize Celery, Suttons' King of the Cauliflowers, Imported Brussels Sprouts, Schoolmaster Potato, Carentan Leek, Green Curled Savoy, Suttons' Student Parsnip, James's Intermediate Carrot, and Suttons' Improved Beet, all in admirable condition. Mr. G. Neal, gardener to T. Southby, Esq., Bampton, Oxon, was second; Mr. W. Iggulden, gardener to R. B. Wingfield Baker, Esq., Orsett Hall, third. Six excellent collections were staged, several of the varieties being stipulated. Messrs. Suttons' prizes for twelve Magnum Bonum Potatoes brought out fifteen competitors. Mr. G. Donaldson, gardener to Lord Kintore, Korthall, Inverurie, was placed first; and Mr. T. Bailey, gardener to Capt. Drake, Shardeloes Gardens, Amersham, second. For twelve Improved Reading Onions there were eight entries, Mr. G. Neal, Bampton, Oxon, being placed first, and Mr. John Baker, Broad Street, Bampton, Oxon, second. The produce in these classes was highly meritorious. For Messrs. Hooper's prizes (offered for six dishes of the following new Potatoes—McKinlay's Pride, Covent Garden Perfection, Grampian, Triumph, Trophy, and Burbank's Seedling), Mr. P. McKinlay, Woodbine House, Beckenham, and Mr. James M. Gilks, Wickham, Newbury, Berks, were the only exhibitors, and were awarded the prizes in the order named.

GARDEN FENCING.

CAN any of your readers offer me suggestions for a cheap, durable, and reasonably safe fencing for the experimental garden (about three acres, mostly unfenced) at Sandy, Beds? Foreign timber, oak and larch poles, also steam sawing and cutting, are tolerably cheap in the locality. A wall, on account of the depth of soil and expense, is out of the question. At present I can foresee nothing better than a close wooden fence for a portion of about 300 feet on the north side, so as to afford a sheltered south border; and for the remainder, of about 16 chains, a post and rail pale fence, the wood for posts being oak, and the posts and rails of red deal, larch I am told being best but more expensive, the wood for rails and pales being rough-sawn diagonally. Is there anything better or cheaper than this? and what are the best materials, especially for the close fence? It has been suggested that old railway sleepers would make good and cheap posts, and black Italian poplar for the boarding of the close fence. If railway sleepers are used should they be sawn in two? At what depth in the ground and distances apart should the posts be placed for the close and pale fences? and what the sizes, thicknesses, and distances of the posts, rails, pales, and boards? Will two or three arras rails be necessary for a 5 feet or 5-feet 6-inch fence? What is the best material to coat it with? and what should be about the complete cost per chain of the close and pale work?—T. LAXTON, *Bedford*.

PRUNING SHRUBS.

THE timely and sensible notes under this heading on page 361 induce me to call attention to the important fact, that shrubs chosen without due thought or knowledge of the leading peculiarities of their fully developed forms often leads to crowding, which it is sought to prevent by a system of hacking and hewing unworthy of the name of pruning. Almost all ornamental shrubs become so naturally with very little assistance from the pruner's hands—no more, in point of fact, than the "removing one of the leaders when two are forming," or cutting a few points off to impart balance and symmetry, as "PRACTICALIST" points out, provided they have the full benefit of light and air on every side. Far better have a dozen really well-grown specimens than a hundred wretched starvelings crowded together in an unmeaning jungle, often battling for bare existence. For securing handsome shrubs thinning, transplantation, and re-arrangement are much more important than pruning, the necessity for which they in a great measure enable us to avoid when practised with requisite promptitude and care.

In addition to its beneficial effect upon the shrubs the process of thinning places many thriving young specimens at our disposal for the enrichment and decoration of other parts of the garden, and so a new shrubbery planted thickly in the first instance for the production of a certain immediate effect becomes, for a time at least, a nursery whence we can gradually withdraw a store of shrubs at our own convenience and at any

favourable moment of the planting season. That season has again come round, and is likely to be a busy one, for the past summer was remarkable for the robust growth of almost all trees and shrubs. Above all plant early and plant well, and so avoid those vexatious losses so frequently resulting from tardy planting and a dry spring; for it is those scathing parching blasts from the bitter north-east that so often cause branch and leaf to shrivel and to disfigure the garden with those unsightly objects—half-dead shrubs.—EDWARD LUCKHURST.

CELOSIA PYRAMIDALIS.

ALONG with this I send you a few sprays of *Celosia*, which are extensively grown here for autumn and winter decoration. It is a wonder they are not more generally and extensively cultivated than they are, for few plants are more ornamental and useful at this season. They last in bloom for months, and are very lasting in a cut state.—D. THOMSON, *Drumlanrig*.

[We never saw such handsome plumes; the crimson variety combining elegance with richness in colour in a remarkable degree, and the yellow variety is extremely chaste. They represent a splendid strain of a valuable section of *Celosia*, and have been admirably cultivated.—EDS.]

NOTES AND GLEANINGS.

"AN OLD EXHIBITOR" writes—"Some of your grateful readers would propose to join in a little TESTIMONIAL, to take the form of a silver inkstand, as a slight tribute of gratitude to our 'returning officer,' Mr. JOSEPH HINTON, for his valued labour of love now extended over several years; and I feel sure many of your readers who have benefited by the election of Roses would feel obliged if the Editors of the Journal would kindly undertake to receive their subscriptions for this purpose."

—We have received a long letter from Mr. Wills on the subject of a COLONIAL MUSEUM FOR LONDON, in which he assumes that "the Council of the Royal Horticultural Society have taken steps with a view of allocating a site for the Colonial Museum the situation I had the honour of suggesting in my memorial to His Royal Highness the Prince of Wales and Her Majesty's Commissioners of 1851." As we are in a position to state that the Council of the Royal Horticultural Society have taken no such steps as were indicated in Mr. Wills's letter, and that such a matter is quite beyond their province, we suspect that Mr. Wills must be labouring under some misapprehension on the subject, and we have therefore thought it better that this letter should not be published.

—VISITORS to the CRYSTAL PALACE during the past three weeks must have greatly admired the fine display of Chrysanthemums grown by Mr. Thomson. The plants during previous years have been arranged in a semicircular group at the front of the orchestra, but this year it has been found necessary to place them in other parts of the building. The change is an improvement rather than otherwise. Splendid groups are now arranged at both ends of the great transept and in one of the side courts. The most striking blooms are those of Golden Empress of India. These are indeed magnificent, and undoubtedly the finest that have ever been produced. All the varieties of Queen are similarly remarkable for their great size, as also are Prince Alfred, the Beverleys, Guernsey Nugget, Bronze and Yellow Jardin des Plantes, Lady Hardinge, Dr. and Mrs. Sharpe, Abbé Passaglia, Peter the Great, Lady Talfour, Mr. Murray, Alfred Salter, Golden Eagle, and John Salter. Very rich are Mount Etna, Julie Lagravère, and Bernard Palissy; and a white reflexed variety of moderate size, and extremely floriferous demands special attention—Sœur Melanie; for general decorative purposes and for affording a supply of cut blooms for vase decoration this is one of the best varieties that can be grown. About four thousand plants of Chrysanthemums are grown at "the Palace," and the display has never been finer than during the present autumn.

—We have seen a very useful contrivance introduced by Messrs. Tidcombe & Son of Watford, Herts, called the GRAVEL-WALK METAL SCRAPER MAT. The name indicates its use. It is to be placed at the entrances to residences, conservatories, greenhouses, and flower gardens, to clean the feet from accumulations of gravel, which too frequently cling to them in certain states of the weather. This it does very effectually, as we have proved by using it; and as the material of which it

is composed is iron, it is far more durable than anything of a similar nature made from vulcanite, cocoa-nut fibre, or such perishable materials. Why should it be called "a mat?"

—A LINCOLNSHIRE CORRESPONDENT informs us that the RUSSIAN TRANSPARENT APPLE has been selling in the local market at 4s. the stone of 14 lbs.—more than double the price of ordinary Market Apples. In the same market the selling price of Beurré Diel Pear is 5s. per stone. On the above grounds our correspondent recommends the fruits named as being profitable for market purposes.

—A GRAND and extensive display of CHRYSANTHEMUMS is now arranged in VICTORIA PARK for the gratification of the "east-enders" and visitors generally. The plants are in pots and have been excellently grown. They are arranged under canvas, the front of the improvised tent, facing south, being rolled up during fine days. The group is about 100 yards in length and 9 feet wide, the taller plants at the back being 7 feet in height, the others in front sloping down and finishing with Pompons little more than a foot high. There is thus a face of bloom of about 900 square yards in extent. Between three and four thousand plants are employed, and the group has, as may be expected, a very imposing appearance; hundreds of blooms are of exhibition quality. Upwards of 120 large-flowering varieties are grown, and about thirty varieties of Pompons. Recently the weather has been unfavourable for visitors, but during fine days the numbers attending to inspect the display prove how much the flowers are admired, and how thoroughly, and deservedly, Mr. McIntyre's efforts to render the Park to the fullest extent possible enjoyable and attractive are appreciated.

—WE are informed that the excellent arrangements of the PUTNEY SHOW were due to Mr. Stevens of St. John's Nursery, who gave valuable assistance to Mr. Moore, the Secretary.

—"A METROPOLITAN NURSERYMAN" writes to us as follows on ROSE-SHOWING:—"I am very glad to see in your last issue the letter signed 'A LOVER OF ROSE SHOWS,' because I think it is quite time that we metropolitan nurserymen had a share of the prizes at the great Rose tournaments. What your correspondent says as to the uselessness of our competing with those who usually carry off the prizes is quite correct, and for the reasons he mentions—viz., unfavourable conditions of soil, atmosphere, &c., and the much smaller numbers that we have to cut from; so that I hope the National and other Rose Show committees will offer prizes for suburban nurserymen and also for amateurs."

—STANDARD CHRYSANTHEMUMS, three or four varieties being grafted on one stock, are really attractive when well grown. By far the finest we have yet seen were exhibited at the Walton Show by Mr. Ploughman. The stems were nearly 3 feet in height and the heads 2½ feet in diameter, not trained on umbrella trellises, but grown in a more natural manner, the shoots being bent and secured to each other. It is important that varieties be selected for this mode of culture that flower at the same time. Those grafted on the same standard by Mr. Ploughman were Mrs. Halburton, Venus, Mrs. G. Rundle, George Glenny, Mrs. Dixon, and Hereward, all of which produced excellent blooms. They were much admired.

—ONE of the finest ZONAL PELARGONIUMS for winter decoration, writes "A CONSERVATORY FOREMAN," is DAVID THOMSON. Its large glowing crimson-scarlet trusses never appear more freely than during the dull months of the year, and few flowers are now more rich and useful. The plants flower freely in a temperature of about 45°. This valuable variety was raised by Mr. Pearson at Chilwell, and is well worthy of cultivation for the purpose indicated.

—"D. J., *Honick*," writes as follows in reply to "A PUZZLED HOUSEWIFE," as to the best way to PRESERVE SOFT FRUIT, such as Gooseberries, Cherries, Currants, Plums, Apricots, Damsons, and Peaches:—"After filling the bottles with fruit, place them in a fish kettle in cold water, packed closely with soft hay to prevent them from shifting. After the fruit is cooked take them out and fill them with boiling water and cork them at once, not permanently; let them stand till cold, then uncork and fill up with salad oil; then cork and tie down tight and seal them closely. Treated such the fruit will keep for years; in fact, I have known a Melon to have been over twenty years in the bottle and taken out fresh. I may mention that the coarse wax should be used, and have it boiling in a pan, and dip the bottles in till the corks

are covered, which will take two or three dippings at least. But to be thoroughly successful the fruit ought to be in the best possible condition, thoroughly sound, and only use one sort in a bottle; for instance, if two or more sorts of Gooseberries are used in one bottle they never keep satisfactorily."

CENOTHERA FRASERII.

CENOTHERA FRASERII is a showy erect-growing species, in favourable soils attaining a height of from 2 to 2½ feet. The flower stems are branched and somewhat thickly covered with oval dark green leaves. The flowers, which are light yellow, are borne on leafy racemes, and appear in succession from the end of May to September. It is less of a night bloomer than

Fig 59.—*Cenothera Fraserii*.

many of the other species, and is well worth being included in collections of hardy herbaceous plants. It is also one of the hardiest, and will do well in any good garden soil, but prefers a mixture of sandy peat and loam. I have seen many years ago a variegated-leaved variety in cultivation, but it was in no sense more ornamental than the normal form, and now seems to be lost. A native of North America, propagated by seed and by careful division early in spring.—R. D. TAYLOR.

THORN APPLE.

THIS plant, *Datura Stramonium*, is not as much grown as it deserves to be. It is a very pretty plant for subtropical beds. Well cultivated it will rise from 2 to 3 feet high, and be the same in diameter. Its foliage is glossy green, and it produces pure white funnel-shaped flowers. Its seed pods are not much unlike the husk of the Horse Chestnut, but oval instead of round, and covered with sharper spines. The pods should be gathered when full grown, and the seed be preserved until the bed or border it is proposed to grow it in has received its spring dressing. When the plants have become 3 or 4 inches

high single them. To a mixed bed they are a great addition. I find the plants do much better if treated in that way than they do if transplanted. Besides being ornamental it is useful. The leaves gathered when full grown, dried, and mixed with an equal quantity of tobacco and smoked, give great relief to anyone suffering with asthma.—S. TAYLOR, *Castlecroft, Wolverhampton*.

HOLEYN HALL,

THE SEAT OF MAJOR WOODS.

MANY gardens of moderate extent are, by the excellent manner in which they are kept and the good cultivation that is practised in them, equally worthy of note with gardens of greater magnitude. The grounds and gardens of Holeyne are noted for their attractive appearance; and the admirable condition of trees, plants, and vegetables affords testimony of the ability of one of the most highly esteemed and best gardeners in the north of England, Mr. Cooke. For a long period prior to Major Woods becoming the owner of Holeyne Mr. Cooke was engaged there, and his services both as a landscape gardener and a cultivator were splendidly recognised by his late employer, who bestowed on his valued servant a life annuity of £100. With such tangible evidence of the gardener's worth Major Woods retained his services, and has proved their value now during several years.

Holeyne Hall is pleasantly situated near Wylam, a few miles from Newcastle-on Tyne. It is on rising ground overlooking the valley of the Tyne, and commands a fine view of the bold and picturesque hills across that river. The mansion is sheltered from the north by a skirt of trees, in which the Austrian Pine predominates, and gives proof of its usefulness as an evergreen screen tree. South of this sheltering belt, and between it and the pleasure ground proper, is a small pinetum, where specimen Conifers are tastefully disposed on grass. Handsome examples of *Piceas nobilis* and *Pinsapo*, *Pinus Douglasii*, *Cupressus Lawsoniana*, *Wellingtonias*, *Deodars*, &c., command attention, and in an open space amongst them the croquet ground is formed. Separating the pinetum from the pleasure ground is a belt of shrubs and some fine timber trees. Associated with the trees are evergreens and deciduous flowering shrubs, which grouped artistically form an admirable northern boundary to the dressed grounds and flower garden. These extend from the mansion westwards. Contiguous to the mansion is a terrace walk, from which broad flights of stone steps flanked with vases conduct to the lawns below. These are ample, and afford the necessary relief to the stonework on the one hand and the bold clumps of shrubs on the other. The flower garden is not a modern mass of colour that startles the visitor by its brilliancy; on the contrary the beauty is of a sober kind, and is not confined wholly to the summer season. The flower beds are large—sufficiently so to contain dwarf flowering shrubs and hardy plants, with here and there a specimen Holly and Thuja. Hardy Heaths and Alpine plants have a share in the decorations. Other beds during the summer contain an unique collection of succulents, such as *Aloes*, *Echeverias*, *Sempervivums*, *Haworthias*, *Pachyphytons*, *Kleinias*, and *Rocheas*—fine old plants that were grown and cherished at Holeyne before plants of this nature became fashionable in the London parks. Other beds contain flowers, mostly in mixture, some gay, others sweet, some ancient, others modern, but shrubs, Conifers, and hardy flowers preponderate, and especially noticeable are grand clumps of Pampas Grass. Some of the shrub groups are rendered additionally attractive by having bold examples of rockwork arranged on their margins, and on which American and Alpine plants flourish, and to which Yuccas and dwarf Conifers afford agreeable variety. These well-covered rocks with Ivy-clad mounds are a prominent feature of the grounds, and have a pleasant satisfying appearance which only age combined with good keeping can impart. Shrub groups and belts, isolated specimens of evergreens and Conifers, with here and there a bed or fringe of flowers, are so disposed that something of interest attracts at every turn, and the comparatively small grounds are made to appear large—at least, a considerable time may be spent in examining their diversified attractions.

The pleasure grounds extend to the kitchen gardens, which slope towards the south. The garden wall next the pleasure grounds is rendered attractive by ornamental climbers—Ivies, *Ampelopsis*, *Loniceras*, *Clematides*, *Azara microphylla*, &c.—the border next the wall being planted with Roses, the oppo-

site side of the walk being a Rhododendron border backed with taller shrubs. The walk between the two borders is 100 yards long; and the borders sloping to the walk, and the walk itself to the Tyne Valley, afford an extensive view of the distant hills through a floral vista of great beauty during the spring and summer months. Such are some of the attractive features of Holeyn. We turn now to the more useful yet not much less enjoyable enclosures devoted to the growth of fruit and vegetables.

In the walled kitchen garden we find what is rarely seen except in gardens that have long been under the charge of the same manager—namely, grand espalier fruit trees. These trees are models of good training, the result of years of attentive care. The branches of these trees are horizontally trained as “straight as gun rods” and of great length. They are about a foot apart, and are studded with spurs “close at home,” and bear abundant crops of fine fruit. Than trees such as these few are more profitable considering the space

they occupy, and nothing imparts a better or more appropriate appearance to a kitchen garden. The walls, too, are well covered with well-trained and profitable fruit trees, such Pears as Marie Louise and Jargonelle being grown on the south wall, and these produce splendid fruit. The vegetable quarters by their productiveness and cleanliness indicate that the same care is bestowed on them as on the ornamental portions of the grounds. At the front of the kitchen garden is the hardy fruit garden. It is bounded by shrubs, and intersected by grass walks kept close by the mowing machine. But the trees are the prominent attraction. The standard orchard trees have been trained, and are as regularly pruned as the espaliers; the branches are consequently thinly disposed and are studded with spurs to the base. In a notoriously bad fruit year these trees were laden with fruit, the finest crop that came under my notice during the year of my gardening rambles from Kent to the Grampians.

The glass structures remain to be briefly noticed. They are

Fig. 60.—HOLEYN HALL.

not extensive. The vineries are about 100 feet in length, and produce a good supply of excellent fruit. Peaches, Plums, and Apples are also grown under glass in a lean-to structure 150 feet in length; Peaches being chiefly trained on the back wall, and the Plums and Apples being grown as bushes in the border. The latter consist chiefly of Calville Blanche, Newtown Pippin, Cox's Orange Pippin, Melon Apple, and Dutch Mignonne, all of which are well adapted for and are highly worthy of orchard-house culture. Smaller houses, also frames, are devoted to plants for decorative purposes. The houses were erected by Mr. Bowman of Newcastle, and were heated by Messrs. Walker & Emley of the Neville Iron Works—firms of good repute in the district, and even beyond it. It may be truthfully said of the gardens and structures at Holeyn Hall that every corner was occupied, and every portion clean and ornamental.

The gardener's house demands a note from its great age and comfortable character. A date on it is prominent—1687. Though venerable, it, like its tenant, yet appears strong; and those who best know Mr. Cooke hope that it will afford him shelter for many years to come. As prominent ornaments of one of the rooms are a handsome wine case, with an inscription telling that it was presented by Col. Burrell and officers of a regiment stationed in Newcastle in recognition of the

excellent fruit supply from Holeyn; also gold medals and silver cups which have been won in public competition.

Mr. Cooke is admittedly one of the most useful members of the working Committee of the flourishing and successful Botanical and Horticultural Society of Newcastle—a Society that was seldom more successful than during the year when Major Woods was its honoured President.—J. WRIGHT.

TEA AND NOISETTE ROSES.

It is seldom that even the most critical reader can take exception to the opinions of the “HEREFORDSHIRE INCUMBENT” in his remarks about Roses; yet I, as a tyro in Rose-growing, was struck with wonder at one or two of his remarks that recently appeared in the Journal. Surely the “HEREFORDSHIRE INCUMBENT” has grown Bouquet d'Or, which is, unless I am mistaken, a seedling from Gloire de Dijon. Is it possible that this lovely Rose does not open with him? My short experience, too, of the two Roses, President and Perle de Lyon, is just the reverse of his. I have grown both Roses in the Weald of Kent clay and in my present garden of light gravelly soil, and yet in both gardens President has shown himself a weak grower, while Perle de Lyon has been very robust. I may say that I have seen the latter in a very light

soil in Yorkshire equally robust. *Souvenir de Monsieur Peron* I do not know, but *Souvenir de Paul Neyron* is a cherished friend of mine. I shall be much interested to know if my experience of these Roses is singular.—KENTISH CURATE.

CHRYSANTHEMUM SHOWS.

SOME shows that we are able to record this week demonstrate how extensively and well the Chrysanthemum is cultivated by those who give special attention to that flower; and the crowds of visitors who attend the exhibitions afford ample evidence that the shows are admired, and that the skill of the cultivators is appreciated. First in order of date comes

WALTON.

The district of this Show embraces the parishes of Walton, Weybridge, Oatlands, and Hersham, a district remarkable for its attractive woodland scenery and salubrity, and hence contains the residences of many gentlemen who have good gardens and employ skilled gardeners. That they can grow Chrysanthemums is evident, for the Show held in the Oatlands schoolroom on the 14th inst. was a splendid one. We have seen better plants of the large-flowered varieties and better incurred blooms, but seldom, if ever, saw such well-grown standards, and never saw Pompons equal to a few of the plants staged. The display of cut blooms of Japanese varieties was also excellent.

Large-flowering specimens.—The first prize (a silver watch in lieu of a cup) for six plants was won by a point by Mr. Ploughman, gardener to Mrs. Allen, Weybridge, with dwarf, healthy and well-bloomed specimens 3 feet in diameter. Mr. Polley, gardener to H. Rogers, Esq., Oatlands Park, was second, and Mr. Cornhill third. For four plants Mr. Burns, gardener to E. A. Rigg, Esq., was an excellent first. Mr. Rowman, gardener to J. J. Wilks, Esq., Oatlands; Mr. Millican, gardener to H. Corbett, Esq., Walton; and Mr. Boxall, gardener to T. H. Hickley, Esq., Walton, had the remaining prizes, all staging creditable specimens. The best plants in this section were of Chevalier Domage, Lady Hardinge, George Glenn, Master Forsyth, King of Denmark, General Brainbridge, Mrs. Dixon, and Hereward. Standards.—In the class for four plants Mr. Ploughman staged three magnificent specimens—Mrs. G. Rundle, G. Glenn, and Mrs. Dixon, the fourth plant being inferior. The three plants named had stems 3 feet high, the base of the heads being $3\frac{1}{2}$ feet in diameter, and were about 3 feet to the apex. They were not closely trained, but resembled trees rather than plants, each bearing upwards of two hundred fine blooms. They represented a new style of training—free, natural, and pleasing—and the Judges honoured the growers and themselves by awarding him the first prize. Mr. Cornhill, who was second, staged splendid, closely-trained, umbrella-headed specimens, fine in foliage and blooms. Messrs. Polley and Millican had the remaining prizes. For two plants Mr. Burns was first with Mrs. Dixon, a perfect model of close training with two hundred blooms, and G. Glenn fine; he was closely followed by Mr. Reynolds and Mr. Masters, gardener to F. Day, Esq., who had the remaining prizes. In the class for pyramids some sharp-pointed spires about 8 feet high were staged, the plants having a base of about 18 inches. The prizes went to Messrs. Polley, Reynolds, and Cornhill in the order named. Mr. Burns staged the best single specimens—Mrs. Dixon, a semi-globe $3\frac{1}{2}$ feet in diameter and admirably grown; so also were those of Messrs. Polley and Millican, who had the remaining prizes.

Pompons.—Mr. Polley won the first position for six plants (dwarfs), one of which, Maroon Model, resembling Bob but lighter, was about faultless; it was $4\frac{1}{2}$ feet in diameter—a plant of wonderful excellence in all points—flowers, foliage, and training. Mr. Cornhill was second, his Model of Perfection being most beautiful, and Mr. Masters third. For four plants Messrs. Reynolds and Boxall secured the prizes. In the single-specimen class Mr. Reynolds had the premier position with a grand plant of Mr. Astie (not easy to grow) $4\frac{1}{2}$ to 5 feet in diameter, and about a foot high; Mr. Polley was second with White Cedo Nulli, and Mr. Masters third with Aurora—a fine class. Standards.—Keen competition, the plants being both numerous and very fine. For four specimens the prizes went respectively to Messrs. Reynolds, Polley, Cornhill, and Ploughman, and for two plants to Messrs. Masters and Millican. The noteworthy varieties were Mdle Marthé, Rose d'Amour, Aigle d'Or, James Forsyth, Miss Nightingale, and Marie Stuart. Pyramids were not good. The special prizes given by the President of the Society, H. Corbett, Esq., for plants grafted with not less than two varieties, were won by Messrs. Ploughman, Polley, and Millican. A special note of the best plants will be found in another column. We have dwelt particularly on the plants exhibited because of their great excellence. The other sections of the Show we must pass through more rapidly.

Cut Blooms.—Messrs. Reynolds, Cornhill, and Masters secured the prizes for twenty-four blooms, and Messrs. Ploughman, Burns, and Boxall for twelve blooms, all staging creditable collections. The varieties best represented were Prince Alfred, Golden

Empress of India, Bronze and Yellow Jardin des Plantes, Queen of England, White and Golden Beverley, Lady Hardinge, St. Patrick, Cherub, Mrs. Dixon, Nil Desperandum, Countess of Derby, Alarm, Mr. Jay, Baron Beust, Barbara, and Alba Multiflora. Messrs. Cornhill, Reynolds, and Russell shared the honours for twelve reflexed varieties, the first-prize collection comprising Triomphe du Nord, Dr. Sharpe, Golden Christine, Mr. Forsyth, Gazelle, Mons. Lucien Barthiere, Chevalier Domage, Progne, Undine, Julie, Christine, and Sulphurea Superba. Japanese varieties constituted a grand feature of the Show, the collections being numerous and competition close. Messrs. Ploughman, Masters, and Cornhill secured the prizes for twenty-four blooms; Mr. Burns being very highly commended, and for twelve blooms the winners were Messrs. Reynolds, Boxall, and Russell. The finest blooms exhibited were of Baron de Prailly, Ne Plus Ultra, Gloire de Toulouse, Nuit d'Hiver, Dr. Masters, Grandiflora, Fulton, Bismarck, Elaine, Garnet, Fair Maid of Guernsey, Apollo, Red Dragon, Red Gauntlet, Yellow Dragon, The Cossack, The Daimio, Sultan, Fulgore, and La Nymph. Mr. Masters easily won chief honours for large-flowered Anemone varieties, and for small-flowered varieties (three in a truss and very beautiful), Messrs. Cornhill, Masters, and Reynolds were the prizetakers. The most attractive triplets were of Miss Nightingale, Antonius, Marie Stuart, Dick Turpin, Madame Montels, President Morel, Mr. Astie, Mrs. Wyness, Firefly, and Astrea. The same exhibitors secured the prizes for reflexed Pompons, the best being—of Whites, Mdle. Marthé, White Trevenna, and Marabout. Yellows, La Parnasse (primrose); Berol, good; and St. Michael, fine; Rose—Model of Perfection and Duraflet. Reds—Bob and Maroon Model. Orange—Aurora Borealis.

Special prizes were given for floral ornaments and bouquets of Chrysanthemums, Mr. Masters securing first honours in the gardeners' class, and Mrs. Townsend in the ladies' section; Fern fronds being largely incorporated in the winning examples. Special prizes were also given by H. A. Rigg, Esq., for twelve incurred blooms, which were won by Messrs. Burns, Cornhill, and Reynolds with excellent stands. The Show, a remarkably fine one, was admirably managed by Mr. Masters, the Secretary.

BRIXTON, STREATHAM, AND CLAPHAM.

On November 13th and 14th the ninth annual autumn meeting of this Society was held in the Tulse Hill Skating Rink, a place admirably adapted for arranging to advantage large collections of plants and flowers. The Show was superior to those of previous years; the cut blooms were of the same excellence, while the specimens were much better and numerously exhibited. Extensive collections of both fruit and vegetables, together with sufficient Ferns and other foliage plants to give relief to the cut blooms, added greatly to the effect of the Exhibition. The arrangements were very satisfactory as made and carried out by the zealous Secretary Mr. W. Hall.

For six large-flowering Chrysanthemums five collections were staged. Mr. W. Hall, gardener to W. Stevens, Esq., Springfield, was worthily awarded the first prize for plants beautifully flowered and trained. They were described on page 364. The varieties exhibited in this group were Mrs. Haliburton, Faust, Mr. Brunlees, Mrs. Dixon, Mrs. G. Rundle, and Lady Talfourd. Mr. Cherry, gardener to Max Slee, Esq., Lingham Court Road, was a very good second, exhibiting well-finished plants of Alma, Mr. G. Glenn, Mrs. Dixon, Mrs. G. Rundle, Venus, and Christine. Mr. Young, gardener to T. Hicks, Esq., was placed third, and an extra prize was awarded to Mr. Howes, gardener to Mrs. Bennett.

The class for six Pompons was not a good one, and the prizes were awarded to Mr. Cherry and Mr. Weston, gardener to D. Martineau, Esq., in the order named. Pyramid Pompons were particularly good, especially the first-prize collection from Mr. Hall. Mr. Howes and Mr. Livermore, gardener to F. Webb, Esq., were placed second and third respectively. In the class for standard Pompons Mr. Hall was again awarded premier honours for massively bloomed plants, Mr. Howes and Mr. Livermore following in the same order as in the class for pyramid Pompons.

For the single specimen Chrysanthemum Mr. Cherry won with an elegant plant of Julie Lagravère; Mr. Hall being awarded the second prize and Mr. Livermore the third.

Several collections of twenty-four cut blooms were staged, and the post of honour was awarded to Mr. Ottaway, gardener to T. Hepburn, Esq., for a very even collection, consisting of Queen of England, Empress of India, Golden Empress, Cherub, Fingal, Prince Alfred, Plenipo, John Salter, Princess of Wales, Golden Beverley, Rev. J. Dix, Beverley, Lady Hardinge, Nil Desperandum, Jardin des Plantes, Prince of Wales, White Globe, Mr. Brunlees, Mr. Gladstone, Lady Talfourd, White Venus, and Antonelli. Mr. Howes was awarded the second prize; Mr. Livermore and Mr. Holmes, gardener to G. Storey, Esq., equal thirds. Mr. Ottaway was also first in both the classes for twelve and six blooms, and for twelve large-flowering Anemones and twelve Anemone Pompons, the whole of which he staged in admirable condition. His collection of large-flowering Anemones comprised Empress, Gluck, Fleur de Marie, Margaret of Norway, Prince of Anemones, Louis Bonamy, Madame Godereau, and St. Margaret; while his Pom-

pons, which were another grand lot, consisted of Madame Montels' Perle, Mr. Astie, Rose Marguerite, Calliope, Antonius, Regulus Firefly, Dick Turpin, Marie Stuart, and Madame Chalonge. A splendid collection of twelve Japanese varieties came from Mr. Howes, and won the first prize. Particularly good were Grandiflora, Dr. Masters, Fair Maid of Guernsey, Comtesse de Beauregarde, Elaine, The Sultan, Garnet, Red Dragon, Cry Kung, Cossack, and Meg Merrilees.

The Ferns, fine-foliage plants, and Orchids were very creditable. Messrs. Hall, Staplehurst, Cherry, Hone, Wright, Young, and Keeler exhibited some very good collections. The dinner-table decorations were very pretty and chaste, especially the first, second, and third prize collections. Messrs. Crisp, Keeler, and Weston were awarded the prizes in the order named. Some splendid fruit were exhibited, particularly Apples and Pears, also several extensive collections of vegetables, which were of a very high degree of excellence. This was altogether a very fine Show and was numerously attended.

DARTFORD.

For several years past this Society has every autumn held the annual Exhibition in the Victoria Assembly Rooms under the superintendence of the energetic Secretary, Mr. W. Shelton. This year the Show was particularly good, but we missed from its ranks those stands of large and truly admirable blooms always exhibited by Mr. H. R. Hards, who has since the last annual meeting been called to his long home, and by his death the Society has lost their strongest and best amateur friend, and one whose collections never failed to obtain the premier prize. Notwithstanding the want of these superb collections there were vast numbers of cut blooms, also specimen and other plants. Mr. Dancer, gardener to S. Mart, Esq., was very successful amongst the specimen plants, which are by his skill beautifully finished. Mr. Pendred was a very successful exhibitor of cut blooms both of the incurved and Japanese varieties. As we have already named most of the varieties in other reports it is not necessary to repeat them. Mr. Carter, gardener to W. White, Esq., and Mr. Dancer were amongst the other chief prizetakers for cut blooms in the professional classes; while Mr. Evitt, an amateur, exhibited some superb collections. We were pleased to see that several cottagers also exhibited.

The collections of fruit from Mr. Clifford White were splendid. Messrs. Carter and Dancer also contributed good collections, which were very much admired. The Grapes which were staged by Mr. Green, gardener to R. S. Dunbar, Esq., were well finished and much praised.

Several other exhibits call for special mention, but our space forbids. Mr. Shelton and the Dartford Chrysanthemum enthusiasts are to be congratulated on their successful meeting.

CROYDON.

This is only the second season of this meeting, and we were very pleased to find a great improvement both in the training of the specimens and in the quality and quantity of the cut blooms over last year. There was not a very strong competition among the plants, but those exhibited by Mr. Brett, Mitcham, were very well finished and evenly trained. Mr. Brett also carried off all the first prizes, with the exception of one class in cut blooms. This exhibitor must have a most extensive stock to be able to produce so many perfect flowers. Messrs. Orchard and Fewell were other successful exhibitors of cut blooms. Mr. Brett's collections of twelve Japanese varieties and twelve distinct varieties of large-flowering Anemones were very fine indeed. The latter consisted of large and well-finished plants of Fleur de Marie, Gluck, George Sand, Madame Godereau, St. Margaret, Prince of Anemones, Louis Bonamy, Acquisition, King of Anemones, Lady Margaret, Mrs. Pethers, and Empress; while his Japanese collection comprised The Daimio, Sarnia, Comtesse de Beauregard, Fair Maid of Guernsey, Grandiflora, Magnus Bonum, Bismarck, Gloire de Toulouse, La Nymph, Red Gauntlet, Elaine, and Dr. Masters. Mr. Orchard was placed second in both of these classes. A few very creditable plants were exhibited by Mr. Podger, a shoemaker by trade, the plants being bloomed in his workshop, and the first prize for twelve blooms (amateurs) was awarded to Mr. Reed.

Fruit was excellently represented by Mr. Chaff, gardener to C. H. Goshen, Esq., Shirley, who was awarded the first prize for Black Grapes, Apples, and Pears. Mr. Chaff also received the first prize for an excellent collection of vegetables. That the Show was a great improvement on last year no one will doubt, and great praise is due to Mr. A. C. Rofey, the Secretary, and his hard-worked Committee, for bringing together such an autumn display.

WESTMINSTER AQUARIUM.

The Borough of Hackney Chrysanthemum Society held in the above building on the 19th and 20th inst. perhaps the finest Show of the season. The entries for cut blooms were very numerous, and with very few exceptions the blooms were of a very high quality. The Japanese blooms were shown in greater numbers than we have ever seen before, and the grotesque and brilliant

blooms were greatly admired. The plants exhibited were of the very best, but the competition here was not so keen as among the cut flowers. The arrangements of placing the specimens, &c., were ably carried out under the superintendence of Mr. Holmes, but the "secret" plan adopted of judging is as unnecessary as it is perplexing to those whose time is valuable. It is utterly impossible to take a correct report of any exhibition when the visitors are admitted, and that in a space of only a few feet for a passage. Our reporter was present for nearly three hours before the cards with the exhibitors' names were placed before the exhibits.

For the best collection of ten Chrysanthemums in 1½-inch pots a first prize of a silver cup valued five guineas, offered by the Royal Aquarium Company, was worthily awarded to Mr. Hall, gardener to W. Stevens, Esq., Springfield, Tulse Hill, for several of the same magnificent plants as were exhibited at the Brixton and Streatham Horticultural Society last week, and consisted of Mrs. Haliburton, magnificent; Golden George Glenny, perfection; Lady Talfourd, very good; Mrs. G. Rundle, Faust, Mr. Brunlees; and Pompons Bob, Mdlle. Marthé, Calliope, and Antonius. Mr. J. Levesley, Isleworth, was awarded the second prize with slightly larger plants of Lady Hardinge, Mrs. G. Rundle, Bronze Jardin des Plantes, very good; Julie Lagravere, Mdlle. Marthé, Mrs. Dixon, Hero of Stoke Newington, and the brilliant-coloured *Odonatum purpureum*—a good collection, but not so beautifully and symmetrically trained, besides falling a little short of the quality of the first-prize collection. Mr. J. Holmes, gardener to J. Hicks, Esq., Manor Lodge, Upper Clapton, was placed third. In the class for six plants, the same size pots, Mr. G. Drain was the only competitor, and was awarded the first prize for plants large and well trained, but wanting in finish of flower. Mr. Drain and Mr. Hall were placed equal first for good collections. Mr. Bengar, gardener to T. G. Fletcher, Esq., was placed third for four large-flowering standards; and Mr. Pricknell, gardener to Mr. Bowerbank, Stoke Newington Green, second.

For six Pompons in 8½-inch pots the first prize and silver cup were awarded to Mr. J. Levesley, Isleworth, for a very beautiful collection, the colours very bright and the plants well flowered. This collection consisted of Antonius, Cendrillon, Prince Victor, St. Michael, La Parnasse, and a well-flowered plant of Bob. Mr. W. Hall is a very good second with grandly flowered pyramids of White Cedo Nulli, Antonius, Golden Cedo Nulli, Mdlle. Marthé, Mrs. Holt, and St. Thais. Mr. Henderson was placed third. Mr. C. Bengar, gardener to T. G. Fletcher, Esq., Upper Clapton, secured the first prize for four standard Pompons with Silver Cedo Nulli, Bob, White Cedo Nulli, and Antonius. Mr. J. Holmes was placed second, and Mr. Prickett third.

Fine-foliage plants were exhibited by Mr. Pricknell and Mr. Bradley, who were first and second respectively. Mr. Gilbey, gardener to C. Miller, Esq., secured the first prize for table plants; Mr. Jordan, gardener to J. Boustead, Esq., Wimbledon, was placed second for a very neat and elegant six; and Mr. Bradley third for a very pretty collection.

Nine classes were set apart for incurved blooms for twenty-four, twelve, and six. Three classes were open to nurserymen and gardeners residing in the boroughs of Hackney or Finsbury only, a similar number for amateurs in the same locality, and three classes open to all comers. The first prize for twenty-four in class 10 was awarded to Mr. J. Holmes, gardener to J. Hicks, Esq., Manor Lodge, Upper Clapton, for a very even stand, having good blooms of John Salter, White Beverley, Golden John Salter, Princess of Wales, Queen of England, Jardin des Plantes, Mr. Brunlees, Empress of India, Lady Hardinge, Eve, Rev. J. Dix, Golden G. Glenny, Venus, White Venus, Mrs. Heeles, Golden Eagle, Barbara, Mrs. G. Rundle, Hero of Stoke Newington, Isabella Bott, Lady Slade, Prince of Wales, Princess Teck, and Cherub. Mr. W. Holmes, Frampton Park Nursery, was placed second for a collection somewhat larger but a little past their best; Mr. G. Drain secured the third prize. For twelve blooms in the same division Mr. G. Langdon, gardener to Drs. Munro & Adams, Brook House, Clapton, was a very good first with Mr. Brunlees, Empress of India, John Salter, Miss Thurya, Prince Alfred, Princess of Wales, Barbara, White Venus, Nil Desperandum, Golden Beverley, Princess Beatrice, and Mrs. Haliburton. Mr. Bengar was second, and Mr. Holmes third, all exhibiting well. Mr. Bengar was first in the class for six, exhibiting John Salter, Princess Teck, Mrs. Heales, Rev. J. Dix, Barbara, and Lady Hardinge. Mr. J. Holmes second, and Mr. G. Langdon third. Mr. C. Butters was first for twenty-four blooms (amateurs) with a very creditable collection, and also first in the class for twelve blooms. Mr. T. J. Godwin secured the second place. Nine collections were staged in the open class of twenty-four, and Mr. E. Sanderson, Willesden, was awarded the first prize and the silver cup as the best twenty-four blooms in the Exhibition. They were all neat and of good size, consisting of Prince Alfred, Queen of England, Venus, G. Glenny, Nil Desperandum, Mrs. Heales, Lady Hardinge, Princess Teck, Golden Eagle, Mrs. Rundle, St. Patrick, Cherub, White Globe, Enamel, Princess Beatrice, Aurea Multiflora, Prince of Wales, Mr. Brunlees, Barbara, White Venus, Duchess of Wellington, Eve, John Salter, and Princess of Wales. Mr. E. Berry, Roehampton, was

awarded the second honours; and Mr. Wildman, Southampton Street, Camberwell, the third; Mr. Hillier, Wandsworth, fourth.

There were twenty competitors in the open class for twelve blooms, and Mr. Sanderson again secured the first prize and silver cup for a magnificent collection of Venus, Barbara, Lady Hardinge, St. Patrick, Eve, Nil Desperandum, Princess Teck, Cherub, Mr. Brunles, Mrs. Heales, Prince Alfred, and Princess of Wales. Mr. G. Pocock, Fairlawn, Wimbledon, was placed second; Mr. G. Ottaway, gardener to J. Hepburn, Esq., third; and Mr. Mease, gardener to C. W. Newman, Esq., Wyncote, Liverpool, fourth with a collection of very large blooms, somewhat rough, and hideously set up with ornamental papers underneath each flower. This collection certainly exhibited extraordinary cultivation, but did not possess that attractive neatness we are accustomed to see in the metropolitan shows. There were about twenty competitors for six cut blooms (open) and the premier prize again fell to Mr. Sanderson. Messrs. Charlton, Pocock, and Reeve were second, third, and fourth respectively. Mr. Hillier was first with a good stand of twelve Anemones.

JAPANESE.—These were a very grand lot extensively shown, the majority of them were of most excellent cultivation. There were several collections staged for twelve blooms in not less than six varieties. Mr. Himell, gardener to F. Davis, Esq., Anglesea House, Surbiton, gained the first prize with a very highly cultivated collection, amongst which we noted The Daimio, Chang, Bronze Dragon, Fair Maid of Guernsey, Jane Salter, The Sultan, Red Indian, James Salter, and The Cossack. Mr. Jordan was a very good second, and Mr. Berry, Roehampton, third. For twelve distinct varieties to include Red Gauntlet, Sarmia, Ethel, and Peter the Great, for which a silver cup was offered by Messrs. Dixon & Co., there were eight competitors, two collections of which were so evenly matched that the Judges had some little difficulty in deciding. Eventually the cup was awarded to Mr. Jordan for a most magnificent stand. Fair Maid of Guernsey, Grandiflorum, Striatum, Baronne de Prailly, quite 9 inches across; Gloire de Toulouse, Yellow Dragon (excellent), Red Dragon, Fulgore, and the four named. Mr. Starling and Mr. Hillier exhibited good stands, and Mr. Starling was worthily awarded an extra prize. Mr. Jordan's was decidedly the freshest collection. Messrs. Dickson & Co. exhibited an extensive collection and received an extra prize; so also did Messrs. E. G. Henderson and Son, who were awarded certificates for M. Delaux, Nuit d'Automne, Père Delaux, and Rosa Bonheur, all very promising Japanese varieties.

GLOUCESTERSHIRE ROOT, FRUIT, AND GRAIN SHOW.

THE sixteenth annual Exhibition of this highly popular and well-managed Society, offering a prize list of £150, was held on November 9th, and may justly be described, in spite of two most disheartening fruit seasons, as a great success.

The roots, grain, and kindred products were exhibited in a tent having a passage into a large room of the Spread Eagle Hotel, which was entirely devoted to a really fine display of Apples and Pears. It was with the latter that the writer is concerned, as the short time the train allowed him precluded his inspecting what from a mere passing glance he could see was a most interesting display, especially of Potatoes.

As usual at these exhibitions the Apples are divided into three classes—dessert, culinary, and cider, special classes being reserved for varieties of local or world-wide celebrity. Pre-eminently among the former stands out as a prime favourite the Ashmead Kernel as a dessert fruit, a variety the public generally will allow to be unequalled in flavour in its proper season—after Christmas; indeed, so popular does this Apple linger in the recollections of the good citizens of Gloucester that until very lately the trunk of the original tree, which succumbed to its destiny about fourteen years ago, has been kept in a cellar and worked up into small articles to enshrine its memory. There were ten entries against seventeen last year; still the competition was very spirited, and the prizes awarded to healthy clean-grown specimens. The writer did not notice in a single plate the sometimes very distinct flush of crimson on the sunny side, as is the case occasionally when grown in the soil of Herefordshire. Mr. Phelps of Tibberton and Mr. Cadle of Longcroft were the winners in this class.

The special class for Ribston Pippin was numerously competed for, and both prizes taken by admirable collections, though the same can hardly be said for Nonpareils, which were exhibited poorly both in quality and quantity.

As far as the number of plates, and beauty, size, and healthful appearance of the Brandy or Golden Harvey Apple is concerned, this class left nothing to be desired, but at the risk of chronicling what many will consider rank heresy, the writer does not consider either one of the collections shown to be the true old historic Apple of this name! It is far too large, not the right shape or colour, and certainly deficient in the exquisite "cognac" flavour to which perhaps this Apple owes its name more than to its high specific gravity. At any rate, the Golden Harvey of Herefordshire, the chief habitat of this Apple in the seventeenth

century, is quite different, and it will be interesting if the question now raised does not end here. A great feature in the Exhibition were the large collections of dessert Apples, for which there were twenty-three entries, but two only put in an appearance. Is it possible that the correct standard of the orthodox size for dessert fruit may not in the case of this collection have been strained a wee bit too far? as it seemed to the writer that many of the varieties exhibited were far too undersized to be characteristic specimens.

In the class open to tenant farmers for dessert fruit there was only one exhibitor, Mr. H. Organ Breadstone, but his was a collection in itself, numbering nearly seventy varieties, though including somewhat incongruously both culinary and cider Apples. Most specimens were marked unknown. Of those named several were purely local. A variety marked the Brumage (Birmingham) Pippin came in for a great share of attention, showing, identically alike in all six specimens, two Golden Pippins united together through their ovaries, presenting two perfect eyes and one stalk, with an elongated potato-shaped superficial appearance. The first prize was carried off by Messrs. Wheeler, the well-known seedsmen of Gloucester; the second prize by Earl Ducie of Tortworth Park.

In the first-prize collection there were very characteristic specimens of Court of Wick, Court Pendu Plat, Sturmer Pippin, and Lamb Abbey Pearmain. All the varieties were named in both collections; Adams' Pearmain, doubtless inadvertently, alone being an exception. Calville Blanche was shown green and miserable, quite a burlesque on that waxy and healthy-looking Apple so generally seen and admired in Paris. By-the-by, why does this eminent firm, who know how to do the right thing so well, fall into the vulgar habit (fashionable at Apple stalls) of French polishing, without any respect of variety, the whole surface of each of their Apples? In the second collection chiefly to be noticed were Duke of Devonshire, Bess Pool (true), Claygate Pearmain, and Ribston Pippin. The Blenheim Pippin—a great favourite at Gloucester, as indeed everywhere else—was well shown, though not particularly highly coloured, and had a special class assigned to it. Mr. Phelps carrying off the first and Mr. Mayo second prize. Warner's King and Mère de Ménage were grandly exhibited in the culinary class, excluding Blenheims. A plate of the old historic Costard was very much admired, and would have well deserved an extra prize. In this class, open to tenant farmers, the nomenclature was bad, nearly every variety being either marked wrongly, notably the Cat's-head, or "unknown." A highly coloured Apple—no doubt local, aptly named Port-wine—was worthy of notice. F. B. Littlewood, Esq., carried off first prize for dessert Apples, single plate, with fine specimens of Cox's Orange Pippin; Mr. J. Chadborn second prize with Dutch Mignonne, the specimens being far above the usual size for dessert. The best new variety of dessert Apple went to Earl Ducie with an Apple after Royal Pearmain, and of a somewhat similar but higher flavour, and more compact shape.

The first prize for the collection of culinary Apples was also credited to the Tortworth orchards, and very clean grown and large the specimens were, especially Waltham Abbey Seedling (Golden Noble), Erabant Bellefeur, and Golden Russet. That favourite variety Cellini (perhaps too late in the season) was not in good condition. Gloria Mundi also was small, and certainly did not earn its synonym of the Monstrous Pippin. A large useful-looking Apple named Greaves' Pippin was unknown to the writer, and looked a very long keeper. B. St. John Ackers, Esq., took second prize with a much smaller collection, but of great excellence, in which that beautiful and useful variety Golden Winter Pearmain was superbly shown.

Pears did not muster in great force. The prizes for collections of dessert Pears were taken by J. B. Littlewood, Esq., with fine specimens, among others, of Beurré Diel, Colmar d'Aremberg, Marie Louise, and Chaumontel. Andrew Knight's varieties (Monarch, Rouse Lench, and Broom Park) were well represented. That fine Pear Duchesse d'Angoulême was poorly shown, while Doyenné du Comice, perhaps the best Pear we have, was strangely absent from so good a collection. Specially worthy of notice were Winter Nelis, Beurré Duhamel, Joséphine de Malines, and Beurré Superfin. Alexandre Lambre looked well, but although fashionable is third-rate in both flesh and flavour, and unworthy of a place in a first-class collection. It only remains to state that G. Deane, Esq., took first prize with Marie Louise (single plate), and second prize fell to Glou Morceau. Time failed to get more than a glimpse at the cider and Pear collections. The fruit seemed far larger than in Herefordshire, as might have been expected from growing in a better soil and less exposed situation. Interesting also it was to notice so many historic varieties both of Apples and Pears.—THE HEREFORDSHIRE INCUMBENT.

WORK FOR THE WEEK.

KITCHEN GARDEN.

GLOBE ARTICHOKEs that were cleared of the old leaves and cleaned will have made some growth and become hardened. Snails and slugs, especially in wet soils, are often troublesome, doing much mischief by preying upon the tender leaf stems

beneath the soil. It is a capital plan to take a little soil out around each stool and give a sprinkling of quicklime, and then fill up with ashes around each plant, about a foot in width all round and 3 or 4 inches thick, which we find the best preventive of slugs. The space between the rows and plants may be covered with litter up to the stools 4 to 6 inches thick, for though this vegetable is hardy, and in light soils will do without protection, yet the less the plants feel of the winter the earlier they will produce heads the following season. Late-sown Turnips should be looked over, and those large enough should be pulled up and stored in sand for immediate use. By removing these the remainder of the crop will be benefited, coming in for later use, or for greens in spring if required. Leeks in trenches should be earthed up; those on the flat may also be blanched by ashes, &c. No opportunity should be lost in having all vacant ground manured, dug, or trenched as will be necessary. The beneficial effects of fully exposing the soil to the ameliorating influence of natural agencies cannot be too highly estimated, especially where the soil is of a heavy adhesive character. Such soils should be placed in ridges in the roughest manner possible, so as to expose as much of it as possible to the influence of the atmosphere, and light soils must also be turned as a means of destroying grubs and slugs.

Mushroom House.—Maintain a temperature of 55° min. and 60° max., and a moist atmosphere, keeping also the surface of the beds coming into bearing moist; but do so without watering over the Mushrooms, even in the button state, and avoid anything approaching to a sodden state of the soil, rather erring on the side of dryness. Collect material for fresh beds, and make them up before it has become dried and spent by heating violently.

Forcing Department.—In order to produce a regular and liberal supply of forced vegetables the operations requisite must be prompt. A commencement must be at once made with Asparagus, Seakale, and Rhubarb. Strong well-developed crowns, and such as have matured early, should be chosen for this early work, as they will break freely, and the produce will be correspondingly satisfactory. Both Asparagus and Seakale early in the season do better when subjected to the stimulating influence of heat arising from fermenting materials than is obtained by any other means. If there is the convenience of hot-water pipes for top heat it will admit of air being admitted to the Asparagus, without which the produce is flavourless. The various modes of forcing the crops named have recently been detailed in the Journal. Chicory being in request for salading, roots should be introduced into the Mushroom house at intervals so as to keep up a supply, placing them in soil up to the crowns, or the roots may be potted. Endive may also be introduced into the same house for blanching. That in frames and pits will need air upon all favourable occasions, keeping it safe from frost by protection in severe weather, and having a portion tied up as required to ensure a supply of blanched heads. French Beans should be sown in pots at intervals, to maintain if possible an unbroken supply. If Potatoes are wanted early early-lifted sets should be placed in leaf soil or spent tan covered about an inch deep, where there is gentle warmth: 55° is ample. When they are sprouted an inch or so they may be transferred to pots or pits. Maintain a supply of Mustard and Cress by sowings at intervals corresponding to the demand. Cauliflowers, Lettuces, Radishes, and Parsley in frames or under handlights expose fully when the external temperature is over 35°, ventilating freely whenever the weather is favourable, removing any decayed leaves, and stirring the soil about the plants occasionally. If slugs are troublesome dust with quicklime or soot.

FRUIT HOUSES.

Vines.—Heavy falls of snow in some parts and rainfall in others have completely saturated the soil and atmosphere, causing Grapes to damp considerably—Hamburgs particularly, which as a rule were badly coloured this year, and those are not keeping well; but as the leaves are now off one of the great causes of Grapes not keeping well is removed. Slight fires will be required to be kept on constantly to maintain an equable temperature, but this must not be high or it will cause the berries to shrivel prematurely, 50° not being exceeded by artificial means, ventilating freely and early in bright weather so as to prevent moisture being condensed by the berries. The outside borders will have been protected from rains and snow by shutters or other material long ago, and if inside borders too are covered with straw (which if done neatly is not objectionable) the Grapes will keep better—or mats will answer. Covering the border prevents its cracking and prevents moisture arising likely to prove injurious. Vines from which the fruit is cut should at once be pruned, &c., as advised in former calendars, and though the houses may be employed for wintering plants it is advisable to keep them cool, admitting air abundantly in all but very severe weather, a few degrees of frost doing no harm to the Vines, but insuring more complete rest. If plants must be kept in the houses do not exceed 40° by artificial means. Turn over the litter in early houses frequently, replenishing it as the heat declines by working-in fresh manure. Outside borders will need to be covered with long litter and have fresh material added as may be required to maintain a genial warmth. The earliest-started Vines will now be showing signs of growth, so that the

temperature may be slightly increased to 55° min., 65° max. by fire heat, with 10° more from sun heat, proportionately increasing the atmospheric moisture. The ventilation will require to be very moderate, and what is given should be at the top of the house; if side ventilation be employed the cold air should be made to pass the heating surface so as to become warmed, as cold currents of air are extremely pernicious.

Strawberries in Pots.—One of the greatest errors in growing Strawberries in pots is the placing of them in Peach and other houses with open ventilators, where from the piercing currents of air evaporation is constant and excessive, which only wastes the energies of the plants, and not infrequently destroys the roots at the sides of the pots. All plants for early forcing should be in frames, with a view to protect them from heavy rains only; those for late forcing are just as well plunged in ashes in a sheltered situation as anywhere, having a light covering of bracken or straw in severe weather. Drought is the great bane of the Strawberry, therefore those in frames or pits must not be neglected for water, the soil always being kept moist. A batch of Black Prince, Vicomtesse Héricart de Thury, and La Grosse Sucrée should be held in readiness for placing in the early Peach house, to which fire heat will be applied early in next month. It is advisable to make up a bed of leaves about 2 feet in height, and place the plants in a frame upon it, packing the spaces between the pots with damp leaves. The bottom heat at the base of the pots ought not to exceed 65°; 60° is more safe, the top being kept cool, 50° not being exceeded, and when mild draw off the lights. This will tend to promote activity at the roots and to push the crowns. After three weeks to a month of this treatment the pots must be raised if the bed still be warm, so as to inure the plants to bear the temperature of the Peach house without check, as would be the case were they taken from a warm bed direct to the shelves. Plants for placing in vineries to be started next month require similar treatment. We place the pots upon reversed turves about 1 to 1½ inch thick; but this is not essential, though we think advantageous in securing more uniform moisture to the roots. Those having the convenience of a house for forcing Strawberries will find considerable advantage in starting the plants in bottom heat as before advised, and if a pit be employed having means of artificial heat, so as to maintain the top heat at 50° in severe weather, keeping them in it until the trusses are pushing clear of the crowns before removing to their fruiting quarters. Time will not only be gained but the result will be more satisfactory, another batch of plants being forwarded in the pit to take the place of the first as they have fruited. If worms have gained access to the pots they should be expelled with lime water.

PLANT HOUSES.

Greenhouse.—Water should gradually be withheld from Fuchsias which have ceased flowering, and when they have shed most of their leaves the plants may be wintered in a shed or other place from which frost is excluded. It is a good plan to plunge the pots in ashes or other material so as to prevent the soil becoming too dry, it requiring to be just moist enough to keep the wood from shrivelling, yet too much moisture is injurious. Young plants struck in late summer and potted off should be kept on shelves near the glass, repotting as required. Keep show Pelargoniums near the glass, and as dry at the roots as can be done without flagging, also keeping the plants cool and well ventilated. Zonal Pelargoniums specially prepared for winter flowering should be placed in a temperature of about 50°, for though the flowers come more quickly in a higher temperature they are not nearly so durable. If the plants are in small pots do not shift them into larger, but feed them with weak liquid manure. Primulas should be kept near the glass, and if the temperature be kept at about 50° they will flower more satisfactorily and be less subject to damp than in a lower temperature. Cyclamens will be throwing up their flowers, and should be kept near the glass, and have a temperature of 50°. This applies not only to those showing bloom, but to successional plants and seedlings. Carnations for producing flowers in succession through the winter must have plenty of light and a temperature of 50° by artificial means; Mignonette must also have light, or the spikes will be puny. Keep the growths neatly tied out, avoiding the bundling system.

Hardwooded plants are at this season much subject to mildew; any that are infested with it should be dusted with flowers of sulphur, but it must be kept from the roots, where it would prove injurious if not fatal. These plants can hardly have too much air, provided they are not subjected to violent currents and cold dry cutting winds, yet no more artificial heat should be given than to keep them safe from frost.

TRADE CATALOGUES RECEIVED.

James Dickson & Sons, Newton Nurseries, Chester.—*Catalogue of Forest Trees, Shrubs, Evergreens, &c.*

Galloway & Graham, 188, Queen Street, Glasgow.—*Catalogue of Roses and other Nursery Stock.*

Kelway & Son, Royal Nurseries, Langport, Somerset.—*Retail Catalogue of Gladioluses.*

W. Cauldwell, The Ives, Wantage.—*List of Select Roses.*

Francis & Arthur Dickson & Sons, The Upton Nurseries, Chester.—*Catalogues of Select Fruit, Forest, and Ornamental Trees.*

Robert Cragg, Rose Nurseries, Car Colston, Notts.—*Descriptive Catalogue of Roses, Pansies, Fuchsias, &c.*

Lawson Seed & Nursery Company, Edinburgh.—*Catalogue of Trees and Shrubs.*

H. & F. Sharpe, Wisbeach.—*List of Seed Potatoes.*

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

AERATING FLOWER POT (E. H. Clark).—We are informed this proves successful. Opinions from gardeners should be obtained, and if favourable advertised.

PRIMULA SINENSIS (W. Minshall, Dingle).—The specimen you sent is one of those curious sports that are met with in the Primrose. It is frequent in the common Polyanthus, and is distinguished by the old name of "Jackanapes on Horseback." It is not at all common in the Chinese Primrose.

STOCKS FOR APPLES (R. D.).—Both the English and French Paradise stocks are employed. The latter is the dwarfier and most generally adopted, but both induce early fruitfulness.

USE OF LATIN (Lincolnshire Vicar).—All knowledge is useful, but we do not consider that the boy destined to be a gardener need know Latin "grammatically and thoroughly." The Latin dictionary and the "Cottage Gardeners' Dictionary" would suffice.

CINERARIAS GRUB-EATEN (F. E. P.).—If the plants have not pushed up flower stalks you may yet save them and turn them to account by shaking all the soil off the roots and replotting in fresh sound soil, and when well established in it give weak liquid manure regularly.

MARÉCHAL NIEL ROSE (Hebe).—Keep your Maréchal Niel in the greenhouse from the present time, and as it is somewhat weakly clear sheep-dung water would do it much good. You can scarcely expect good flowers by Easter from such a plant. The side shoots of a Cabbage stalk that had borne a good heart would yield good seed. There was no seed in your letter.

TUBEROUS-ROOTED BEGONIAS (Sussex).—Tuberous-rooted Begonias will not only answer in a hot sunny aspect under a wall, but may be planted out in June in any of your flower beds just like ordinary bedding plants. They require a light, rich, sandy soil, and are worthy of it, forming as they do most charming masses of foliage and blossom. It is not advisable to leave the tubers out during the winter.

YUCCAS NOT THRIVING (Idem).—There is something wrong with the soil. Take up the sickly plant and replant in a well-drained station of deep rich soil. Yuccas answer admirably in Sussex, small plants growing quickly to a large size and becoming very ornamental.

POLYANTHUSES (William Hand).—If you write to Mr. Charles Turner of Slough he will, no doubt, be able to supply you with plants of show Polyanthus.

LAYERING MAGNOLIA GRANDIFLORA (W. C.).—The shoots may be pegged firmly in the soil now, but two years will probably elapse before they are rooted sufficiently for removal.

PLANTING TULIPS (John Leland).—The present is a good time for planting the bulbs. They require deep, rich, well-pulverised soil, and a dry subsoil. They should be planted about 5 inches apart in rows 9 inches asunder, and be covered 2 inches deep with fine soil.

PLANTING RASPBERRIES (H. F. C.).—We plant three canes to form each stool, as the plantation is rendered more certain and is in profit sooner than when one cane only is planted. There should be no trouble by suckers. Good gardeners thin out superfluous growths so as insure the proper number of strong well-matured canes for fruiting.

BONES FOR VINE BORDER (Jacko).—We do not approve of burying the flesh of animals in Vine borders. Boiled bones by being more rapid in their action we consider preferable to fresh bones, although the latter may be more lasting, the fat which the bones contain retarding the decomposition of the gelatine.

SEEDS FROM TASMANIA (E. R. P.).—All the seeds you name may be sown in March in a slightly heated frame or greenhouse, the soil to be kept constantly moist and partially shaded until the seedlings appear. They must then have abundance of light and sufficient air to keep them sturdy, potting the plants singly when they are large enough to be handled, keeping them close until established, then gradually inure them to light and air, of which they cannot have too much during the summer.

PRUNING VINES (E. G.).—You may prune your Vines at once, and as they have been so much infested with thrips wash the rods thoroughly with a strong solution of Gishurst or soft soap, a strength of 6 to 8 ozs. of soap to a gallon of water will not be too much. Then turn the Vines outside, protecting them with hay only during severe weather. A few degrees of frost will not injure them. The woodwork of the house should also be thoroughly washed with strong soapy water, and the glass with clear water previously to filling it with plants, the walls also being cleansed and lime-washed if that is suitable. A few days of labour devoted to that work will be well and profitably applied; indeed if you do not cleanse the house completely now you will next year have the same trouble with thrips that you have recently experienced, and the insects if not checked will ruin your Vines. The temperature you name is suitable for the plants, but would be too high for the Vines, therefore turn them out as you propose.

SHADING A CONSERVATORY (T. E. C.).—The mixture termed "summer cloud," introduced last summer by Mr. H. Elliott, seedsman, Braywick, Maidenhead, Berks, is an admirable substitute for the old-fashioned blinds. It is applied to the glass in the form of paint, costing about a penny a square yard. It can be had either of a grey or green colour, and is easily removed in autumn.

CYCLAMENS NOT PRODUCING LEAVES (Idem).—This denotes debility induced either by an undue amount of forcing during the season of growth,

or a system of starvation in summer. They do not like hard forcing, nor is it required, the temperature of an intermediate house of 50° being ample, and liquid manure should always be given throughout the flowering period. Both flowers and leaves will decay at the base if water is poured on the top of the corm. Let, therefore, the top of the corm be always raised slightly above the surface of the soil, and take care not to wet it. Old corms often fail to produce good foliage.

VINES INFESTED WITH MEALY BUG (W. M.).—Prune the Vines as early as possible, remove all loose bark from the stem, and well scrub the rods with a strong decoction of Gishurst compound, 8 ozs. to a gallon of water, taking especial care to work it well into every opening in the bark; also have all the interior woodwork scrubbed with hot soapsuds, and the brickwork whitewashed with fresh slacked lime.

TOBACCO LEAVES FOR FUMIGATING (Idem).—Tie the full-grown leaves in small bunches and suspend them to dry in any available shed—a stoker's should be used at this late period of the year. After they become quite dry suspend them in any shed having no fire and they will soon become limp, and should be laid closely together in a heap to induce a slight fermentation, and as soon as this takes place shake them out loosely, let them remain so for a day, and then put them close together in a box or drawer till required for use. Mushrooms can be grown throughout the winter in a brick pit without fire heat provided you exclude frost. The "Garden Manual," 1s. 9d. post free, contains instructions for growing Mushrooms.

MULBERRY CASTING FRUIT (A. B.).—This chiefly arises from dryness at the roots, the soil being dry and shallow. In that case a few good waterings during drought in summer would probably be effectual; but the fruit also drops before it is ripe in soils that are heavy and wet. The cure in that case is improved drainage.

CAPE CHERRY TREATMENT (Idem).—The seeds you have received under that name are possibly the Cape Gooseberry (*Physalis edulis*). The seeds may be sown in March in light rich soil in pots, placing in a hotbed, potted off when large enough to handle, and when well established removing to a greenhouse, shifting into larger pots as required. The shoots may be tied to a trellis or other support, or be planted out in a border in the house where it can have plenty of light and air, and being duly supplied with water it will fruit freely in autumn and winter. Light loam with a little leaf soil or well-rotted manure will grow it well. Or if they are the Winter Cherry (*Physalis Alkekengi*), the plants may when hardened be planted in the open air in June.

PRESERVING BULBS FROM MICE (Idem).—We have had no experience of coating bulbs with linseed oil and red lead, but we know that Peas thus dressed are rendered tolerably safe from mice. A good covering of sharp coal ashes will often preserve bulbs from mice. The real remedy, however, is to trap the vermin.

LIQUID MANURE FOR VINE BORDER (S. S.).—The Vines being weak give the border a good watering when the Vines are being started into growth, using guano water at a temperature of 90°, 1 lb. of guano to twenty gallons of water. Nine gallons per square yard will equal a rainfall of 2 inches; but half that quantity will be sufficient to apply to outside borders so early in the season, covering the surface with dry litter after the watering so as to retain the heat. When the Grapes are set and fairly growing another good watering should be given the border, and again when they show indications of ripening, using the liquid manure in a tepid state, yet not exceeding 90°, and in double quantity to the first watering, or nine gallons per square yard. No injury will be done provided the drainage is good. Allow as much foliage on the Vines as can be fully exposed to light.

SHRUBS FOR BEDS (Birkenhead).—Your idea of having shrubs as permanent centres and edgings to beds is, though not new, good, but your beds are rather small for shrubs to remain permanently, though with cutting they would endure a long time. For centres Gold and Silver Hollies, Aucuba japonica limbat, Osmanthus ilicifolius argenteo-marginatus, Taxus baccata aurea and elegantissima; whilst for margins the silvery Eucalyptus radicans variegata, Buxus sempervirens aurea nova, Hedera arborea elegantissima, H. arborea aurea, and Erica carnea are suitable, and can be kept of a moderate size for a lengthened period.

VINES FOR EARLY AND LATE HOUSES (C. J., York).—For early house—two Black Hamburgs, one Mill Hill Hamburg, one Foster's Seedling, one Buckland Sweetwater, and one White Frontignan. Late house—two of Muscat of Alexandria, one Alicante, one Mrs. Pince, and four of Lady Downe's.

CLIMBERS FOR LOW GREENHOUSE (Idem).—*Rhynchospermum jasmynoides*, *Kennedyia inophylla floribunda*, *Lapageria rosea*, *Jasminum gracile*, *Hoya carnea*, and *Sollya linearis*.

MARÉCHAL NIEL ROSE IN GREENHOUSE (Rose).—It will succeed trained beneath your greenhouse roof, but will not do so well as where it is shaded by the tree. The border should be 2 feet deep and well drained, but as the soil is gravel drainage may not be necessary. Turfy loam rather strong with a fourth of decayed manure form a suitable compost. If the Rose tree has been grown in a pot the shoots will require little if any pruning, and will produce blooms next summer; but if it has been dug up from the nursery it will be advisable to shorten the shoots considerably, so as to induce a free growth and lay a good foundation for a permanent plant. In the latter case you cannot expect many blooms the first year.

BRIARS FOR BUDDING.—Several correspondents wish to be informed where they can obtain these.

POINSETTIA (A. B. G.).—It belongs to the natural order Euphorbiaceae.

CHRYSANTHEMUMS UNSATISFACTORY (A. T.).—The cause of the blooms being small is not the result of any error in temperature, but arises either from the growth not having been well matured or from poverty of soil. If you grow the plants well during the summer, select good varieties and disbud in good time. You will have satisfactory incurred flowers with the conveniences at your disposal.

TREES FOR ORNAMENT (Cartoon).—You will find no trees answer so well upon limestone as Beech, both the green and purple-leaved thriving well in exposed situations. Limes are fine avenue trees, particularly so the red-twigged. Elms, both the English and Huntingdon, are suitable; and Horse Chestnuts are noble trees, the scarlet-flowered and variegated being especially beautiful. Sycamores succeed admirably in exposed situations, the variegated and purple-leaved being very fine. The scarlet Maples—viz., *Acer colchicum rubrum* and *A. virginianum (rubrum)* are not so extensively planted as they deserve. The Occidental Plane has noble foliage; and the

Black (nigra), Golden (concordia), and Scarlet (coccinea) Oaks have fine foliage, the latter being particularly striking in autumn. Poplars, Black Italian, Lombardy, Ontario, and Silver-leaved, the latter very remarkable, may be mentioned as suitable for moist soils. Birch "The Lady of the Woods" is among the finest of trees, the Fern-leaved Weeping and Silver Weeping being particularly attractive. All those should have stems of not less than 6 feet in height up to 8 feet, with well-furnished heads. Such trees are kept in stock by the principal nurseries, and are frequently transplanted so as to ensure their safe removal. Single trees for lawns move quite safely when of such a size as to be effective. A few of the finest deciduous trees for lawns are *Malus floribunda*, *Æsculus rubicunda nana*, *Laburnum* (Cytisus), Parksi, Scotch and Weeping; Thorns, double scarlet, double pink, and double white; Mountain Ash, *Salisburia adiantifolia*; double-flowered Almond, double-blossomed Cherry, and Stag's-horn Sumach, with a number of weeping trees. All should be of good size so as to be effective at once. It is necessary in planting trees on opposite sides of a drive or entrance that they be of the same kind so as to correspond, for to plant a Beech on one side and a Sycamore on the other would be equally destructive of effect as would a very elaborately chiselled gate pillar on one side and a rough one on the other.

ABUTILON (*Abutilon*).—Your seedling is very good; colour rich yellow, petals short and incurved, and flower of good form. It resembles *Reine d'Or*.

NAMES OF PLANTS (*A. C.*).—1, Send when in flower; 2, *Enonymus europæus*; 3, *Escallonia rubra*; 4, *Leycesteria formosa*; 5, *Polygonum vacciniifolium*. (*Sandgate*).—*Gesneria zebrina*. (*D. M. P.*).—*Cestrum* (?) sp. (the flower withered); 2, *Bouvardia* sp. (*F. P. F.*).—*Hibiscus cannabinus*. (*J. W. Hopkins*).—1, *Cobæa scandens*; 2, *Mercurialis annua*. (*A. H. S. Calford*).—We have had some difficulty in determining the name of the *Dendrobium*, which is, we think, *D. aqueum*.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

THE LAYING-OUT AND DIVISION OF ARABLE LAND.

THIS subject may seem comparatively unimportant until it is considered in its various aspects, when we venture to say it will be admitted to form a most essential item connected with the home farm and its profitable management. Railways have effected a great alteration in the face of the country in every district through which they pass, and these alterations have generally been of great benefit to adjoining properties, including both owners and occupiers, and have suggested that alterations may be advantageously made on many estates not intersected by railways. On various properties and home farms which have been under our management we have found fields in a diversity of shapes; and a removal of fences has been the result, with a great gain of land for cultivating purposes; but taking the kingdom at large very much yet remains to be done, the full advantage of which it is impossible to estimate. Railways, although their formation first called the attention of the agricultural interest to the subject, have absorbed extensive tracts of land in this country; it then becomes a question as to how much land can be gained by well-considered schemes of laying out the available land. In some cases as much land may be gained for agriculture as has been taken by the railway, especially when we consider that by the removal of fences large fields are formed of square or oblong shape, which are an improvement for steam culture and also ordinary cultivation.

The first impediment we have to notice to the proper laying-out and division of arable land are the old crooked fences, and more especially those with high banks and deep ditches. Let us for a moment refer to what was originally the cause of the fences for the division of the land. We can only suppose the object was to keep the boundary and fences against animals, also for drainage of the land; but modern improvements have doomed them to be cleared away, and it is only in a few instances when horned cattle are required to be fed in the fields they may be retained. In all those cases where sheep only are kept the live fences and ditches are not necessary, but quite the reverse; and with regard to the drainage of land it must be considered as good policy to drain and fill-in the ditches as it is to drain the adjoining fields, the pipe drain being a better main carrier for any draining in the field than an open ditch, with its constant expense in scouring, &c. Hedges, ditches, and fences upon arable land usually occupy an area which can be turned to much better account; and upon farms in general, particularly where the land is undulating, they occupy the best land, being usually placed in the lowest valleys,

besides which they encourage the growth of timber, which cannot be grown without loss to the occupier between the cultivated fields. The banks and hedges, too, encourage and protect vermin. We have recently noticed the young wheat just vegetated almost destroyed by rats, and it is found necessary upon some farms in certain districts, particularly where there are many rabbits, to keep some persons continually employed to destroy the rats. Fences, also, from various causes are often badly placed; they are either crooked, thereby enhancing the cost of tillage, or placed where they divide the land injudiciously, for each field should be as nearly as possible of the like soil as regards value and texture. We have often been forcibly struck with the damage arising from hedges even in the most exposed situations along the seacoast and in the hill districts in various counties, where they have been retained ostensibly for affording shelter to the corn fields, for we have seen on the lee side of the hedges great damage caused by the eddy action of the wind on the eve of harvest, the ears of corn being twisted and broken off and the grain beaten out; whereas in the open fields where the wind, powerful as it often is, passes over in a regular way, the corn, waving to and fro almost like the waves of the sea, receives scarcely any damage. Again, where do we find most sprouted corn in a wet harvest? Do we not often see the open part of our fields without damaged corn, whilst near the hedges enough is sprouted to injure the sale of the grain? Look also at the effect of banks and fences in fouling the land. In them sufficient weeds are reared and nursed often to seed the whole farm. It is true that cutting the borders for turf and burning it into ashes, or cutting the border grass for feeding cattle, tends to prevent weeds from seeding, but this is done perhaps only by the best farmers, whilst some of their neighbours' seed weeds enough in their hedges to plant a whole parish. As long as hedges and banks are retained they are sure to contribute to feed the fields with couch and coarse grasses, which the action of the harrows, &c., in turning will testify; and further in the case of what is termed the best kind of fence—a trimmed whitethorn—the cuttings and prunings which are often left on the land cause serious injury to sheep when the thorns enter their feet.

We will now allude to the exceptions where fences are requisite—viz., at the sides of roads, the bounds of the farm, the bounds of premises, &c., and particularly the boundary adjoining the pasture or park lands. These fences should if possible be of whitethorn kept neatly and closely trimmed. Our railway companies often set us a good pattern in this respect. We cannot leave this part of our subject without naming hedgerows, as upon many farms they form the divisions of fields, and the argument is still stronger against them than ordinary hedges. The shape of fields should be square or long with square sides, and may vary in size from fifteen to twenty acres each upon small farms, but upon large occupations they may be set out at thirty or forty acres at each roadway connection, having due regard to the roads and approaches at the boundaries. The fields, likewise, when possible should be of similar soil, in order that the cultivation and course of cropping may be regulated thereby. In the arrangement of fields due regard should also be had to access when labour is going on, such as harvesting of corn, the carting of manure, roots, &c., and the facility for steam ploughing with easy access for the removal of machinery, &c., appertaining thereto. The interest of the proprietor should always be kept in view, in order that the land should yield its full value in rent.

We have now stated what we consider the leading points to be observed in laying out our arable lands, and in order to illustrate the matter more fully we cannot do better than refer to what has been done upon farms of our own and others under our superintendence. On one farm in particular which came under our management we found the arable land divided into eleven fields and separated by fences, some of which were capital whitethorn hedges, others were of high banks and deep ditches; and although they had been for some twenty years kept neatly trimmed, still they were a source of expense, and occupied so much valuable land that we determined upon their removal. The argument against the banks and ditches being the strongest they were the first to be removed. The quickset hedges we retained several years longer; we, however, soon felt convinced of the advantage of removing the whole of them by the benefit we derived from the first removal. At the present time we have no inside fences upon the arable land of this farm. The gain in land was upwards of three per cent. for cultivation, saving of expense for trimming hedges, scouring of ditches, &c., and twenty-one less gates and panels of pales to keep in repair, whilst grubbing the fences furnished sufficient soil to cover the adjacent shallow lands. Access to the different fields is now complete, whilst formerly the fields could only be entered by the gateways. At present any carting can be done by crossing the fields in any direction, making a saving in labour in various ways of at least twenty per cent. In the place of a number of short ploughings there are now, but few, and those consequent upon irregular boundaries, which cannot be altered. Roads at right angles through the farm, giving access to all fields not adjoining a highway, are made with or in some cases without gravel, the latter form being useful

for the ordinary work of the farm; when made in proper form—cast-up, rounding, and being highest in the middle or horse track—the cart ruts only require to be picked in and the outside cast into the middle once a year, which serves to keep the roads in shape and the water tables clean and free, and at the same time keeping the borders of fields neat and well defined at trifling cost by manual labour only. The only additional expense incurred by the removal of inside fences is the cost of hurdles or hurdle gates, amounting to only a few pounds on a hundred acres.

WORK ON THE HOME FARM.

Horse Labour.—The wheat season is now so nearly concluded that the land must be managed in a different way from that which has been sown previously. The principal part of the land not sown is that which has grown a crop of turnips and has lately been in the process of feeding-off by sheep. There may be, however, some land not yet sown which has produced a crop of mangolds, or the seed time may have been delayed on land after clover. Under any of these circumstances it is well to plough and sow as we go; for if the land is ploughed beforehand it is never safe to obtain a favourable seed bed, as our climate after we get into the month of November is usually frost or rain, and sometimes both within twenty-four hours. We have found from our own experience best not to trust the weather but to put on horses enough to make two sets, one to plough the land and another to work the land after the drill or the seedman. In this way, although we have often frosts, yet not sufficient to stop the plough, and the work proceeds continuously through the day, so that in the event of rain setting in at any time all the land shall have been seeded which has been ploughed, and thus securing a seed time under the difficulties with which the manager of a home farm has often to contend in connection with the season for wheat. A few weeks ago we were engaged seeding land for permanent pasture: it seems rather late for such work, but we have on former occasions had capital pasture when seeded late. The land, however, was well prepared by a good clean fallow, and laid into form with plenty of water trenches in the case of cold flat land. One advantage in late sowing is that you have hardly any weeds to contend with. It is said that the frosts will kill the young clover plants whilst in their first or seed leaf. We have never found this the case when suckling and permanent white clover is sown amongst the cocksfoot, perennial, and other grasses, as they germinate quickly and with a strong leaf, which overlaps and shelters the clover plants in their infancy; indeed we have had no instance of failure in obtaining a good plant and growth by late sowing—viz., any time from the 1st of September to the 1st of October.

Hand Labour will still have some connection with wheat-sowing where not finished. The pitting of Swedish turnips, too, will still be going on where they have been early sown and become ripe, or where rabbits and hares are kept in considerable numbers, because the roots are apt to rot in the land unless they were late sown, and will now and at all mild intervals during the winter be in the full vigour of growth. These only will stand severe frost. All others should be pitted or stored in some way in order to maintain their full feeding value. The men will also be engaged in enclosed districts in hedging, ditching, &c., and in the hill countries where watted hedges are made this is the time for doing the work. The odd horse or horses will now be in attendance to the requirements of the cattle and sheep. The former will require hurdles drawn and moved from field to field, also hay for foddering them unless the hayricks are made in the fields where the roots are grown, in which case the shepherd cuts out the hay fresh as he wants it and carries it to the racks. This, however, applies more to stock flocks, as fattening sheep often have hay supplied to them as chaff. The supply of roots for cattle, too, is of some consequence at this time; and when a change of food takes place, whether it be from turnips to Swedes or Swedes to mangolds, the roots before any decided change is made should be mixed, so that the animals may become somewhat accustomed to the alteration of food and not suffer from leaving one kind of roots for another suddenly, as they are very apt to scour and lose condition through a sudden change of root food. For the milch cows cabbages will still be available if grown to an extent capable of supplying them until Christmas, which in ordinary seasons should be done. The horned ewes will by this time have nearly all dropped their lambs, which will require the shepherd's utmost care and attention. The wether lambs should be castrated at about a month old; the strongest animals may be done at three weeks old. Women will now be required to prepare and clean roots for the cutter both for cattle in the boxes and in the field before the sheep, taking care that sufficient for a fortnight's consumption be ready beforehand, otherwise when hard frost or snow overtakes the work it may seriously interrupt the system of feeding. Women also may now be employed in forking out the roots and small bunches of couch grass if found either in the rye, vetches, trifolium, or the clover; for we have found from our own experience, that in loamy and sandy soils in particular, that this mode of attacking the grass is not only the cheapest but the surest, and we may almost say the only way to keep it under, so that the seed time of the various crops may not be delayed or damage occur to the growth of cereals

as well as pulse crops. At about this time the fattening cattle should receive an additional supply of artificial food, and those animals intended for Christmas markets may now have the fullest allowance they will require; we never, however, exceed 4 lbs. of cake and 2 lbs. of meal per day for each bullock.

THE CRYSTAL PALACE POULTRY SHOW.

(Continued from page 379.)

Cochins.—The first Black cock capital in shape and very glossy; his condition good too, indeed he looked as bright as a cockerel in head; second, very sheeny but not large, and deficient in shank feathering; third, not quite through the moult, a good bird with splendid leg-feathering. Hens were good. First, a grand bird all round; second, beautiful in shape and glossy, but too big in comb; third, good in form but not large. The first cockerel we think held the same place at Oxford; his form is very good, but he is decidedly small; second, tall with ugly earlobes; third we liked for his green gloss. We could hardly agree with the pullet awards. First had a high bad comb; second was small and rather Langshan-like in shape; third much better, though a little deficient in leg feather. One shown by Mr. Storer was particularly good.

Cuckoos are certainly a new feature; we had no idea that anyone possessed so large a stud of this variety as Mr. Cuff must have to show eight pens. First were a really remarkable pair; second, too long in tail; third, rather light. Mr. Cuff showed one bird so short on the legs that we think he must have had a "dumpy" ancestor.

Spanish.—The cockerel class was the only large one for this variety. The first cock, good in quality of face, with a stout comb; second, a fresh-looking bird with smaller but very smooth face; third, not so good in comb. In hens, the first was in fine condition, but not very smooth in face; second, very good in the latter point. First and second cockerels well placed, both bright-looking birds with good combs and faces; third, very long in face. Pullets were rather good than numerous; the three winners all capital birds. We missed the name of Mr. E. Jones of Bristol in these classes.

Game numbered 269 as against 206 last year. The increase was chiefly in the Black Red cockerels and pullets, which each had thirty-two entries. Several birds were spoilt by fighting with their neighbours. Mr. Billett would be doing a good service to the Game fancy if he would extend the close wiring by one or two wires further. Black Red cocks (fourteen), first (Pope) was a good bred bird with a fine head, but wanting in bloom; second (Lyon), rather coarse. Mr. Matthew's very highly commended bird, 1157, was a fine bird of good colour and style, and long in head, but rather broad in the tail. 1160 (Voisin) was, if we are not mistaken, the cup bird at Birmingham in 1876; he looked wonderfully well considering his age, and might have been higher in the list but for the loss of his tail. 1161 (Maynard), highly commended, we thought one of the best in the class. In cockerels the cup went to the bird which was second at Oxford, and claimed there by Mr. Field; he is a pretty bird, but will hardly make such a good old one as Mr. Matthew's second (1184), which but for a rather dark eye must have been first. 1169 (Pope), third, good colour, but rather too much feather for a cockerel. We liked Mr. Lyon's fourth-prize bird, 1165, more than any of his other cockerels which we have seen this year. 1166 (Pope) was, we think, fourth at the Dairy Show; he is a neat bird, but has an inclination to a light eye. 1176 (Carrington) looked like the first Dairy Show bird; he has good points, but wants bloom. 1191 (Voisin), undubbed, is a bird full of promise. In Black Red hens Mr. Garnett was first with a bird bred by Mr. Pope; she was cheap at the catalogue price. Second and third both went to Mr. Pope for birds full of the quality for which he is so well known; the second-prize bird was also interesting, as being the mother of the £100 cock; the third-prize bird was one of those damaged by fighting with their neighbours. In Black Red pullets Mr. Pope took the cup for the best Game hen in the Show with a bird faultless but for a darkish eye and a white deaf ear; second (Dr. Etheridge) was a neat bird, but also had a dark eye; third went to Mr. Halsall for a bird which bore a strong resemblance to the Dairy Show winner, and fourth to Mr. Matthew for a pullet which looked like sister to the second. 1210 (Pope), unnoticed, we should have liked to have seen second; 1208, highly commended (Lyon), was pretty, but rather red in the wing. 1219, very highly commended (Lampriere) was very good, as also were 1226 (Green) highly commended, and 1233 highly commended (Maynard). In Brown Red cocks Mr. Martin took the cup with a fine bird, full of quality; second went to Mr. Fenwick, and third to Mr. Matthew. In Brown Red cockerels there were no less than six empty pens, so that there were only nine birds to judge. We preferred second and third (Martin), to the cup bird (Taylor); fourth (Matthew), good colour, but full in feather. Brown Red hens were still fewer in number, as there were only eight hens, but the first (Matthew) we thought might have had the cup for best Game hen in the Show; she was a splendid bird in faultless

condition. 1269 (Fenwick) was a good bird though unnoticed. Brown Red pullets mustered twenty-four, and contained so many good ones that it must have been a difficult class for the Judge to decide upon. First was won by Mr. Warde with a pullet pretty in colour but wanting in reach; second (Watson) and fourth (Fenwick) were of the same type; the third (Webster) was more reachy. We liked 1293 (Voisin) as well as any in the class; 1280 (Martin), 1288 (Bell), 1290 (Coulthard), and 1295 (Cameron), were good birds, though we noticed the class for Duckwing cocks brought some good birds together. First (Martin), a very smart bird, though not quite sound in the colour of the wing; second (Cameron), and third (Martin), both good birds. In cockerels first went to Mr. Matthew for his Oxford bird, certainly the best Duckwing of this season, but sadly spoilt here by fighting. Mr. Martin's second was hardly as good in colour as his birds usually are. We liked Mr. Harley's unnoticed pen 1321, better than his third-prize pen. There were seven Duckwing hens; first (Matthew) was a fine hen of genuine Duckwing colour; second (Lyon) a smart bird with good eyes; third (Thomas) we did not like; we should have preferred 1324 (Staveley), this probably lost a place from being pencilled on the wing. In pullets dark eyes and washed-out colour seemed to be rife. We liked 1335 (Goodwin), very highly commended, as well as any. She was very cheap at catalogue price. Messrs. Staveley's second-prize pullet was free from any defect in eyes and of good colour, which cannot be said for the first-prize bird, though she was only good in shape. Mr. Martin and Mr. Oakeley showed good pullets.

Pile cocks (eight).—First, a good hard-feathered bird, but a trifle thick in one of his feet; second, a good-coloured bird, but rather heavy in figure; third, a fair bird; highly commended 1343 and 1349 possessed merit. **Pile cockerels** (eleven).—First and cup for the best Pile was awarded to a grand stylish yellow-legged bird; second belonged to the same owner, a good bird but not so forward; third, a fair bird but lacking the high breeding of first and second. **Pile hens** (fourteen).—First, a stylish hen; second, nearly equal to first, but a trifle more red on wing; third, too pale in colour; highly commended and commended birds were fairly good. **Pile pullets**.—First, a grand pullet all round, we believe second-prize winner at Oxford; second, a good pullet but not so stylish as first; third, of but medium quality.

Malays numbered fourteen cocks and sixteen hens. A big dark cockerel was first, an old bird second, and a very good White third. The first and second hens were very fair.

Lephorns.—The Brown classes were very large—nineteen cocks and twenty-three hens, showing that the breed has become thoroughly popular. We always find considerable difficulty in making up our minds as to the respective merits of these birds; the first cock was rather dull in colour and not over-good in comb, but well shaped and free from the prevailing fault of squirrel tail; second, a pretty bird of much brighter hue. The winning hens were all in good condition with bright combs; there were others whose form and body colour we preferred. The first White cock a beauty in colour and form, and with really white ears; second, well-shaped but not large. The hen class contained a lot of fair average merit, the first winner we thought well chosen.

Andalusians are again becoming a thoroughly recognised breed, thanks in great part, we believe, to Miss Arnold. First cock well laced on breast; second, a very good bird in capital condition, dark in colour. First, a large hen, very fine and barely through the moult; second and third rather light-coloured.

Sultans (eleven pairs).—The first cock very good, though not quite through the moult; second, remarkable for the very good head and carriage of the cock; third were very yellow, we preferred their owner's other pair.

Langshans.—Only two old pairs, not remarkable, put in an appearance. The cup cockerel was a very glossy bird, exceedingly cochiny in shape; the winning pullets were all large, and the first very green, of the Langshan type.

Any other variety.—A beautiful pair of Silkies first; second, trim small Black Minorcas; third, Dominiques. Mr. Dugmore showed a good pen of White Rumpless fowls.

Bantams (Game).—Black Red cocks (thirty-eight).—First and cup a pretty little bird, but rather long in wings; second, a tight-feathered bird but dull in colour; third, very good, we preferred him to second; fourth, a fair bird, but out of condition; fifth, dull in colour; several of the highly commended birds were inclined to be too large. Black Red Bantam hens (thirty-eight).—First and cup, a good pullet, beautiful in colour with a good red face; second, rather too large but otherwise good; third, a very smart bird; fourth, good in colour but short on leg. Several highly commended were very good, especially 2163, 2166, and 2174. Brown Red Bantam cocks (nine).—First, good in colour but not dark enough in face; second, belonging to same owner, had a beautiful laced breast; third, good in colour but too large. Highly commended, 2183, also too large; 2185 we think deserved a card. Brown Red hens (six).—First, a smart gold-hackled pullet; second we liked better, she had a pretty brass hackle; third, very good, equal to first and second. Highly commended, 2192, a good coloured bird. Duckwing cocks (ten).—First, a good bird and well placed; second not so good, as he had a pencilled hackle, we

preferred third to him. Highly commended, 2194, a fair bird. Duckwing hens (ten).—First, a very smart one, but inclined to have a blue face; second, good in colour but too large; third, a smart bird. Pile cocks (twenty-two).—First, good with yellow legs; second also good, running the first very closely; third, good in colour but too large. Highly commended, 2216, a good bird but had been fighting; 2219 dull in colour; 2224 high in tail; 2225 a good bird, but evidently in ill health. Pile hens (nineteen).—First, small and very neat in feather; second, a fair pullet; third, another pullet, we thought her equal to second. Highly commended, 2343, a good shaped pullet. Several of the highly commended birds possessed great merit.

We think attention should be called to the fact that pens 1293 (Voisin) and 1352 (Colgrove), were highly commended in the Judges' book, though they appear unnoticed in the catalogue. It is impossible that in so large a Show as the Palace there should be no oversight, but the press may lend a helping hand to remedy them as far as possible.

Bantams (Black).—The cockerel in first pen was very small and neat; second contained a glossy but large cock, and a very small hen; third, rather too heavy. Booted.—All the winners were White; feathering seems more cared for than their smallness of size in these days, for the winners were decidedly large. We should have put Mr. Holmes' Black in the list. Sebrights seem to get sadly coarse, and are, we fancy, very inferior to their ancestors which we can remember fifteen years ago. First, very good Silver; second, the same colour; third, Golden. Any other variety. —First, Cuckoos; second, pretty Light Japanese; third, the famous imported Dark Japanese.

Waterfowls do not call for detailed criticism. Mr. Fowler of course was first with Aylesbury Ducks; it was amusing to hear the remarks of the gaping multitude upon his wonderful drake. Pekins are certainly a great addition to our ponds; formerly there seemed so little variety in useful (not so in ornamental) Ducks. There were sixteen pens of them in their class, besides several in the selling class. Rouen drakes and Ducks are now shown singly; there were twenty-four of the former and twenty-three of the latter. We still regret to see prizes given to some birds which we feel pretty sure do not breed, and must be much inconvenienced if compelled to walk. Black East Indians were a beautiful and attractive lot; we thought the cup pair the best we had ever seen, the Duck looking as green as many drakes; there was some difference of opinion on this point, owing to the indifferent light they were in from being shown in an under tier. Second were rather larger but very good, doubtless some of those which we so much admired in their home last summer. The other winners both capital pairs; the competition is very keen in this breed. Any other variety.—First, Mr. Serjeantson's well-known Paradise Ducks; we were amused to hear that this pair contrived to let themselves out of their pens after the judging on Monday, were found quietly walking about in the Palace. Second, Ruddy Sheldrakes; third, Spotted-billed. Surely this class requires subdivision, for several inbreeding varieties and a splendid pair of Mandarins went unnoticed.

Turkeys good, not large classes. We learn that the classes for young Turkeys have been much reduced or spoilt by the impunity with which for years exhibitors of old birds were allowed to win in them. This practice seems now in a fair way to be stopped, and we trust that honest breeders of early poult will take courage. **Geese**.—Gigantic Geese first; Greys again second, and Whites third.

The judging as far as we could learn was thus apportioned:—Mr. Hewitt took Dorkings, Cochins, Aylesbury and Pekin Ducks; Mr. Teebay Brahmas and Game Bantams; Mr. Smith Game and Malays; Mr. Dixon Spanish, Hamburgs, the rest of the Bantams, Waterfowl, and Turkeys; Mr. Tegetmeier French, Langshans, and the remaining varieties, some of them with Mr. Hewitt. We cannot answer for one or two of the Pigeon classes, but believe them to have been thus allotted:—Capt. Norman Hill Pouters, large and small; Mr. Wiltshire Carriers; Messrs. Betty and Louth Dragons; Mr. Esquilant Tumblers, Nuns, Trumpeters, Turbits, Magpies, Archangels, and Runts; Mr. Jones Fantails, Barbs, Jacobins, Owls, Antwerps, and young pairs; Messrs. Jones and Esquilant the collections.

BIRMINGHAM CATTLE AND POULTRY SHOW.

THE figures relating to the entries in the various sections show a general increase in all the more important departments, a result very gratifying to the Council in the face of a new and increased competition.

We anticipate that the exhibition in Bingley Hall will take the lead, as usual, in Shorthorn, Hereford, and Scotch breeds, both in point of numbers and quality, whilst the little Devons will be more at home in London, where the numbers will also be chiefly strengthened in the Sussex classes.

As regards sheep, the place to see Shropshires in perfection is Bingley Hall; and this year, owing, no doubt to the extra £50 prize presented by Messrs. Gibbs & Co., there is much stronger competition in South Downs and other breeds.

The pigs will form a larger display than usual, whilst the roots, corn, and potatoes are all far above the average in number of entries.

The Council, at its meeting on Thursday, made arrangements for the use of the electric light.

During the week the arrangements with the various railway companies have been made as to excursion trains, to which we shall refer more fully next week.

The Hall has been painted and coloured throughout, and will be completely filled, every available inch having been eagerly applied for by local and other leading implement makers. Messrs. Robey & Co. of Lincoln supply the engine to work the dynamo-electric machines.

The Council meet weekly on Thursdays to complete the arrangements.

VARIETIES.

AMONG the best sales at the late Crystal Palace Show we hear that the first Dark Dorking cockerel was bought in at fifteen guineas by his owners; the second went to Lord Tournour for £12 10s.; Mr. Norris's very highly commended Dark Brahma cockerel, price £21, had a "sold" card on him, also the cup Buff Cochins cock, price £20; the cup Light Brahma cockerel, £20; third Spanish pullet ten guineas; cup Silver-pencilled cock and pullet, each ten guineas; and the cup Silver Polish cock, £20. In Pigeons the fourth young Black Carrier was claimed for £32; the cup White Foreign Owl for £15; and last, but not least, the prize Black Turbit cock, bought by Mr. Woods for £26 at Mr. Roper's sale, was claimed by Mr. Burnell for £40.

WE hear that the Langshan enthusiasts are about to have a Langshan show, and to start a Langshan newspaper.

THE *San Francisco Chronicle* says:—"Los Angeles and San Diego counties can vie with the world in the quality of their honey, and the only drawback to extensive foreign demand has been the careless and diversified method of marketing. We are glad to see that there is to be a change in this regard in the southern counties. The process of packing to be pursued in future is described as follows: Upon receiving the extracted honey they place it in large settling tanks of 3000 lbs. capacity, and this, securely covered, is left exposed to the rays of the sun for a day or so. By this process all impurities are eliminated, rising to the surface, and the pure honey is drawn off at the bottom. It is then put up in neat tin cans containing 2 lbs. each, and packed in cases of two dozen each, handsomely labelled. The design is to ship direct to Liverpool."

WINTER TREATMENT OF BEES.

PROTECTION is the word that embraces all, or almost all, that is needful for bees in winter—protection from hunger, cold, moisture, and mice. And this protection is better given to bees in autumn before the winter sets in. It is natural for bees to store up a supply of food for winter before the cold weather comes. When weather prevents them from storing up enough, or when their stores are taken from them, artificial feeding should be resorted to in early autumn, and enough of food given them to keep the bees well through the winter. It is not natural for bees to take up artificial food or even honey in cold weather. How many bee-keepers are concerned about their stocks when the bees decline to take the food presented to them? It should be borne in mind that when the mercury of the thermometer falls to 50° or below it, bees naturally cluster closely together for mutual warmth. In such times warmth is preferred to food. Artificial feeding in cold weather is objectionable, because it may tempt the bees to leave their hives and face an atmosphere too cold for them to live in. But as most of us fail sometimes in doing the right thing at the right time, feeding may have been neglected or postponed, and sometimes we may discover that, owing to the weather of autumn being warm and open, the bees have well nigh eaten all their winter stores. Some hives in my garden, very strong in bees, did eat almost all their winter supply before November arrived; hence I have had to give them a second supply in a warm state and in a warm place. The food was made milk-warm and given to them in a hothouse.

Protection from cold and moisture is helpful to bees. I have heard people say that "a green Christmas makes a fat churchyard." Does anybody believe this? No. Statistics abundantly prove that the death-rate of human beings is higher in cold winters than in milder ones. Even in the vegetable kingdom how much we are indebted for the protection of snow. The cold of winter is a bitter reality to beasts, birds, and bees, as well as to poor half-clad human beings. All hives in Great Britain should be well protected from both cold and moisture. Most people know how difficult it is for frost to penetrate a grassy lawn or field. A good coat of grass wards off the frost from the soil below for three or four days—in other words, it prevents the heat of the soil from escaping. A coat 2 or 3 inches thick of dry soft grass or hay placed around a bee hive, beneath the outer covering, is a great protection to bees in winter, and makes their hive a cosy

nest for early breeding in spring. From moisture without and within bees must be protected. Hives should never be made damp by either rain or internal moisture. The hives that let the moisture of the bees pass off, and do not condense it on their sides, are the best for bees in autumn, winter, and spring. The materials of hives are of less importance in summer. The question of ventilation is one of great importance in apiculture, and will by-and-by command the attention of observing and successful bee-keepers. Not only the hives but also the coverings of hives should permit the moisture of bees to pass out and off as soon as formed.

All that is necessary to protect bees from mice is to contract the doors of hives so that the vermin cannot enter. I have known many hives ruined by mice. When bees are sitting closely together, and a mouse can get at them, it carries them out one by one and eats their heads off. I have heard of an Eastern prince who ordered a dinner of peacocks' brains. It appears to me that mice are very fond of the brains of bees, for they eat nothing but their heads. Both house and field mice destroy bees thus, and eat honey when they can get it.

The only winter work in the apiary that cannot be done in autumn is protection from snow. Bees are apt to leave their hives after a storm and before the snow is melted. When they come out at such a time they fall into the snow and die. Their doors should be closed when snow is on the ground, and opened when it is gone.—A. PETTIGREW.

OUR LETTER BOX.

POULTRY FARM (*H. L. Sarge*).—No poultry farm has hitherto been profitable. Our "Poultry-keeper's Manual" contains all the information we possess.

FEATHER-EATING FOWLS (*A. Withers*).—We know of no cure for this vicious habit. If the offender was kept separate from the other fowls for some weeks and supplied daily with vegetable food only it might cause a reform.

AMERICAN BEE JOURNAL (*G. S. Harding*).—Apply to Trübner & Co., Ludgate Hill, London.

FOOD FOR HORSES (*A. Correspondent*).—Farm horses will require whilst the work is severe two bushels of oats per week and a bushel of Indian corn, the flat sort being cheapest; both oats and maize should be crushed, as some animals do not grind their food properly, some from defective teeth and others from hasty feeding. The allowance of fodder may be hay and sweet straw mixed, about 15 lbs. of each per day, cut into chaff to be mixed with about 12 or 15 lbs. of pulped roots, either carrots or Swedes at present; in the spring mangolds. This root food is essential in keeping the stomachs of the horses in a proper state. If the work is easy during the short days the maize may be dispensed with altogether, and resumed when the heavy work of the spring seed time comes on.

REMARKS.

- 13th.—Fair morning, but after 10.30 A.M. cold and damp with drizzling rain.
 14th.—Wet, cold, dreary day.
 15th.—Another wet day throughout; windy in afternoon.
 16th.—Fine pleasant day; misty towards evening; slight rain in evening.
 17th.—Clear fine morning, sunshine at short intervals; showery afternoon and evening, with squalls of wind.
 18th.—Fine day on the whole, with bright sunshine; only a few slight showers; damp evening; starlight and clear at 11 P.M.
 19th.—Very fine sunny day; foggy in evening.
 Temperature nearly the same as last week. The first three days very unpleasant.—G. J. SYMONS.

COVENT GARDEN MARKET.—NOVEMBER 20.

BUSINESS keeps very quiet, the large consignments of American Apples completely paralysing home-grown fruit, unless samples are exceptionally good. Grapes are in better demand, the bulk of Black Hamburgs being now cut. Kent Cobs quiet at previous rates.

From observations taken near London during forty-three years, the average day temperature of the week is 46.9°; and its night temperature 34.4°.

NOTES ON VEGETABLES.

IN some respects the summer just passed has been a remarkable one in the vegetable garden. There has been something mysterious about the Cauliflower crop in many places. The heads produced in spring from autumn-sown plants were all that could be desired; but successional summer crops, although produced in some instances from the same packet of seed, were very unsatisfactory. Such has been the case here, but the autumn crop of Veitch's Autumn Giant is splendid. It has yet to be seen how the autumn Broccoli, a very important crop, will turn out; at present it promises well.

Carrots with me have been good, but there are complaints about them in some places. I think most people sow Carrots too early; there is no necessity for sowing the main crop before the beginning of May. For my part I have no main crop, but sow successions outside from the beginning of April till the middle of July, the later sowing succeeding Ashleaf Potatoes. Carrots are comparatively hardy; those sown late will stand outdoors till February if we have no severer winter than we have had for several years, and they are of far better quality when taken fresh from the ground. The Early Nantes, a comparatively new variety, is the best I know for quality; it is about the size of the French Horn, and ends abruptly instead of tapering, consequently there is no waste. Those who have carefully tested the difference in quality between the small varieties and the larger will never grow the latter except for cattle. I find many people have made up their minds they do not like Carrots as a vegetable simply because they have never had them sufficiently cooked. To be good they should be boiled fully two hours, so that when put into the mouth they melt like a well-cooked Vegetable Marrow.

Celery I have planted for the first time on the flat, manuring and digging the whole ground alike, and planting the rows about 5 feet apart, with a couple of rows of Lettuce between, to the manifest advantage of both crops. Our soil being very shallow as well as heavy it is decidedly mischievous to trench and lay aside the friable sweetened portion and plant in the comparatively sour and sterile stuff at the bottom of the trench. It is true the plants have generally grown tolerably well, owing to the large quantity of strong manure placed in the trench, but the roots were confined to the trench and had no chance of ramifying a yard on each side as they have when planted on the flat, and consequently wanted more attention in the way of watering. Some of the roots now are cut in earthing-up; but as this happens in autumn when the weather is not often dry they are not likely to suffer much from this, and as the drainage is more perfect through the winter we may fairly expect it to have a favourable effect on the keeping. I think, however, the rows should not be nearer than 6 feet on shallow soils, as with the present arrangement I have but barely sufficient friable soil for earthing-up. We are obliged to place burnt clay or something gritty round the stems when earthing-up to keep away the slugs, and it is done in this way: we rear

and secure a board up on each side of the row about an inch from the stems, fill the space between the two boards with burnt clay, and then bank up with the ordinary soil outside of the boards before removing them. I consider Major Clarke's, or Leicester Red, the best Celery when it can be had, but it is of no use for the winter except in the most favoured localities. Williams's Matchless is perhaps one of the next best in quality, and will stand the winter.

I must again praise the Improved Round-leaved Batavian Endive (not Fraser's, mind; that is coarse and not nearly equal to the old Batavian, but the one sent out by the Messrs. Veitch a few years ago, and figured in their catalogue). I have given up growing Lettuces for salad in autumn and winter in favour of this Endive, for when once the warm weather is gone the Lettuce grows slowly and blanches imperfectly, and this Endive is then decidedly the best, for it hearts well, blanches easily, is quite as sweet as Lettuce is at this time of year, and many people do not know it from a good Lettuce in the salad bowl. With sliced Tomato and a little really good oil it makes, in my estimation, a perfect salad. But I have lost my Tomatoes. I was, like some of your other correspondents, under the happy delusion that glass was a safe barrier against Peronospora; the untimely end of the Tomatoes has taught me differently.—WILLIAM TAYLOR.

THE ROSE ELECTION AND THE TEAS.

I HAVE received a letter couched in courteous language asking me, Would it be too much labour to have an exhibition Tea Rose election? There are various reasons against this—firstly, my time; next, that at this season when the nurserymen are all so occupied with executing orders they cannot give the time to such matters really outside their everyday duties, already sufficiently onerous; and lastly, that I think that we ought to get a fair approximation to the best exhibition Tea Roses from the general election itself. That election was an exhibition election, and I presume that the Tea and Noisette Roses named in that list ought to come out at the head, even in an election confined exclusively to Teas and Noisettes. If, therefore, I state all the votes given to this class of Roses in the general election, it may serve as an assistance to some amongst the readers of our Journal.

Altogether there are twenty-five Roses of this class named. Nine of these have been already mentioned in the list of seventy-two—viz., Maréchal Niel, 39 votes from 41 voters; Catherine Mermet, 27; Souvenir d'Elise, 21; Souvenir d'un Ami, 20; Marie Van Houtte, 18; Devoniensis, 18; Niphetos, 11; Gloire de Dijon, 11; Belle Lyonnaise, 8: these were all named in the list of seventy-two best exhibition Roses. Next to them comes the Madame Bravy-Alba Rosea Rose with 6 votes; Madame Willermoz and Souvenir de Paul Neyron obtain 4 votes each; and Triomphe de Rennes, Jean Ducher, and Marie L. Pernet are nominated three times; then follow Comtesse de Nadailac, Céline Forestier, Madame Margottin, Perle des Jardins, Rubens, Anna Ollivier, La Boule d'Or, Jean Pernet, and Madame Caroline Kuster; while one Tea has a solitary vote—viz., Bouquet d'Or.

These I take it, according to the general election, are the best exhibition Teas. Is there any difference in the more select election of seventy-two varieties? Let us see. There we had fourteen electors, and Maréchal Niel 14 votes, Catherine Mermet 13, Souvenir d'Elise 12, Marie Van Houtte 11, Devoniensis 11, Niphetos 11, Souvenir d'un Ami 10, Marie L. Pernet 6, Alba Rosea 6, again make a muster of nine Teas in the seventy-two varieties, thus far in numbers resembling the other election and differing in names only by the substitution of Marie L. Pernet and Alba Rosea for Gloire de Dijon and Belle Lyonnaise. To continue: Madame Willermoz, Belle Lyonnaise, and Comtesse de Nadaillac muster 5 votes, old Gloire de Dijon has 4 votes, Perle des Jardins and Jean Ducher 3 each; whilst Boule d'Or, Madame Caroline Kuster, Rubens, and Cheshunt Hybrid, assuming this Rose to belong to the class, have only 2 votes each, and Anna Ollivier, Céline Forestier, Madame Hippolyte Jamain, Madame Margottin, Souvenir de Paul Neyron, and Souvenir de Madame Pernet have each only a solitary vote. Curiously enough, here also I make the total mentioned to be twenty-five! and the difference between the two lists is simply the naming of Cheshunt Hybrid, Madame Hippolyte Jamain, and Souvenir de Madame Pernet, instead of Triomphe de Rennes, Jean Pernet, and Bouquet d'Or. Taking these two lists together we thus get twenty-eight Roses named in these varieties.

It may further be noted that in the seventy-two varieties nine Teas are named, or exactly one in every eight Roses. Carrying on the comparison, the ratio is nearly the same—viz., 25 in 180, or rather over one Tea in every seven Roses.—JOSEPH HINTON, *Warminster*.

GROWING GRAPES IN COOL HOUSES.

THOSE of us who live in the south, far away from the coal districts, find the cost of fuel an important, often a burning, question in more senses than one. How to keep down the coal bill is a problem which we find very difficult to solve, nor can we hope for much sympathy from northern gardeners, for it is a matter on which they hardly bestow a second thought. "How about coal?" said I once to one of these favoured individuals residing in the south of Scotland, and who had just been enumerating his glass houses by the dozen. "Eh," said he, "Coal? Why, we just send a cart to the pit!" He actually had a coal pit on the estate, and thought no more of it than I do of sand, peat, or chalk, or any other substance which happens to abound in our particular locality. With an unlimited supply of fuel the temptation to apply artificial heat in changeable or ungenial weather, "just to keep the thermometer steady," must prove irresistible, hence the idea that fuel is an indispensable necessity for Grape-growing.

During the past season I have put the matter to a much more severe test than that advised by "A KITCHEN GARDENER" for a vinery, containing in addition to Black Hamburg, two strong canes of Lady Downe's Seedling, two of Alicante, two of Madresfield Court Muscat, and one of Mrs. Pince's Muscat, and had not a single fire from the starting of the Vines till the crop was fully ripe. Now for the result. Madresfield Court Muscat before has never been so good in this house, bunches and berries being of good size, and that delicious flavour for which this Grape is so much valued was fully developed, and the colour was all that could be wished; in fact, the fine crop of fruit was thoroughly well finished, as was that upon the whole of the other Vines. The Black Hamburg and Madresfield Court Muscat are all used, Mrs. Pince's Muscat being in use now, while the Alicante and Lady Downe's Seedling are still untouched, and I have no doubt will keep well as long as may be required.

To close the ventilators with the thermometer at 90° from solar heat is a standing rule during the swelling of the fruit, only broken during the second swelling of the fruit of Lady Downe's Seedling, when if the weather prove sultry the ventilators are thrown wide open night and day, and thus all loss from scalding is avoided.—EDWARD LUCKHURST.

NOVELTIES IN THE ROYAL GARDENS, KEW.

CRINUM FORBESIANUM is one of the most important of the introductions to Kew this year, and certainly ranks high among the finest species. It appears to be very dwarf in habit, the scape not being longer than a foot. The bulb is of large size, from 7 to 8 inches diameter and ovoid in form. The leaves are just appearing and seem inclined to spread;

their margins are finely ciliated. No other species produces so large an umbel. The flowers numbered over two dozen, and each of considerable size, something in form like *C. ornatum*, to which set it belongs. This species embodies a fine feature in the colouring of the flowers; each segment has a broad line of deep rose along the centre, and this rich colour shades off to a pure white margin. It was derived from the Lebombo mountains north of Natal. This plant is in the Begonia house. Close at hand is a remarkable *Hippeastrum* with green flowers, introduced by Messrs. Veitch and named *H. calyptratum*. It appears to flower freely, scapes having been thrown up in succession. In the next house *Mesembryanthemum fragrans* is the only one in effective condition, and this is extremely pretty, with five large yellow flowers nearly 3 inches across, and, as the name denotes, fragrant, and that very sweetly. It is one of the creeping kinds, with deep green very fleshy leaves, forming the tongue-leaved section.

One of the prettiest plants in flower and rare is *Trichinium Manglesi*, in perfection, too, for many weeks past. It is an *Amaranth*, native of the Swan River, and the rosy flowers are mixed with fine white hairs in a dense roundish cluster. It is nearly hardy, but is best grown under glass, at least during the greater part of the year. It is very slow of increase unless taken in hand the right way, and this is by cutting up the rootstock. The leaves are rather scanty, and the flower stalks slender and naturally perhaps decumbent, so that a good specimen can only be had by grouping. We should recommend early propagation by the above means, so that plants are ready for the open ground in May. In September those likely to flower should be taken up to bloom under glass, since no other plant could suffer more from splashing of dirt by heavy rain.

Economic plants are not of general interest, but we may note one of considerable beauty, though only an annual—a class, by the way, increasing greatly in popularity. This is *Guizotia oleifera*, allied to *Heliosis*, and bearing flower heads about 2 inches across with fine bright yellow ray. It yields the important Ram-til oil of India, used in India as a condiment and for burning in lamps. The plant assumes a pyramidal form and flowers freely. The leaves are oblong or lanceolate, and light green in colour. *Osmanthus fragrans* is worth mention for its most delicious perfume, utilised by the Chinese for perfuming tea, hence its position in this house. As an idea we should rather prefer a plant in flower on the table itself, and the tea aroma would mix with its perfume agreeably without doubt. The leaves are dark green and handsome. The plant admits of cutting freely, so that it can be kept to any size or shape, and sprigs are freely available without injury. It is grown from cuttings, or may be grafted on Privet and planted against a wall, though it flowers freely only under glass.

Under our heading above some pardon is requisite for mention of *Aphelandra cristata*, which no doubt will be granted on account of its extreme showiness. It was a novelty 150 years ago. While several other kinds have prettier leaves, such as *A. Fascinator*, no subsequent introduction has surpassed its fiery scarlet flowers, and so we recommend for it a wide cultivation still.

A fine new *Machæranthera*, finer than any hitherto introduced, is in great beauty. No name has yet been given, but a figure will be published in the "Botanical Magazine," no doubt under the genus *Aster*, to which the above has been reduced. It appears of biennial duration, though if sown early, as in this case, flowers are produced the same year. The flower heads are over 2 inches across, of deep bluish purple, and very numerous produced in large panicles. It came from Colorado, apparently with much greater success than the beetle.

In the Succulent house a very fine form of *Agave schidigera* will shortly open flowers. We admire the plant in the first place, the flowers being rather of interest and without beauty. Every leaf is thickly clothed with white threads, which, curling about, afford an unusual kind of beauty. As well known, the collection of this genus is important, some kinds being represented here only, and of this number we might mention *A. dentata*, a plant in the way of *A. attenuata*, but with very minute and numerous teeth. We are especially charmed with a nice plant of *A. utahensis* with narrow silvery leaves, radiating and, as it were, forming a star. It is said to be hardy, but a plant so rare and choice cannot be permitted to prove the question. Of the new species *A. Desertii* and *A. Shawi* are good representatives.

In the Cape house a pretty miniature *Hyacinth* has been flowering under the name *Milla sub-biflora*. It turns out to

be *Hyacinthus corymbosus*, L., a native of the Cape. It grows in a dense tuft only about 3 inches high. The leaves are subulate, among which appear numerous lilac flowers, two or three together on each stalk. Herbarium specimens answer the name much better. The flowers are numerous, in broad clusters, so that by giving plenty of room to the bulbs an equal number of flowers might be produced from each.

THE ROSE SEASON OF 1878.

"WYLD SAVAGE" has given his *résumé* of the Rose year. I should like to give (as I have been accustomed for some years) my review of the past season so far as the queen of flowers has come under my notice. As I have already given some notice of the Rose shows at which I have been privileged to assist, commencing with the pleasant gathering at Holmside near Reigate, of the Brockham Rose Society on June 27th, and ending at Newton Stewart on July 16th (for I do not take into account exhibitions at which the Rose forms a small part, but those only where it is either exclusively the object of the show or else the *pièce de résistance*), it will be unnecessary for me to enter into any detailed reference to these separately, but merely to draw some general deductions as things have struck me.

And first with regard to the season. In my judgment it was not a good Rose year. The winter was very fatal in many soils to the Manetti; the constant wet completely rotted the roots, and I have seen and heard in gardens in Cheshire, Kent, Dorsetshire, and other counties of wholesale losses from this cause. The early part of the spring gave promise of an abundant growth and fine blooms, but spring frosts in some places and the cold cheerless weather in the early part of June completely disappointed these expectations. I was inundated with letters about our National show, complaining that the fixture was too early, that it would be impossible to have blooms in, &c.; then came that extraordinary burst of tropical weather in the last week in June, baffling all expectations and destroying the hopes of many a small grower. So that again we have to say that the season was an exceptional one, as they have been for three or four years; and as exceptional means in this case bad, it is to be hoped that we may soon come to normal seasons. The result was, that taken as a whole Roses were not so good as I have seen them. There was a general want of substance and what I would call finish; and while, as I shall notice, some astonishing blooms were exhibited, the general character was below the average.

The popularity of the Rose seems not only not to be diminishing but increasing. I have been asked this year to officiate as judge at places in our southern counties which are little known, situated on branch lines of railways little frequented by the travelling public, where the Rose was the only flower shown, and was sufficient to draw together all the neighbourhood; while far away in the west of Scotland I hear that the Rosarians' Society closes its year with a handsome balance in hand. The influence, too, of our National Rose Society is telling. Two-day shows have been abolished in some places and will be soon a thing of the past; its rules of judging have been eagerly sought for and are being acted upon; while the immense demand made upon growers for sale, of which I hear from all quarters, shows how widespread this love for the Rose is, and I think I may fairly say has been largely fostered by the work of our National Society.

I do not remember any season when there has been a greater scarcity of good new Roses. Looking down the long list which reached me last November from Charles Verdier I hardly see one that has made any mark. I did see in early spring a bloom of Boiledeau which struck me as very fine, but nothing else has come prominently forward. Whether there may be some flower which has hitherto "wasted its sweetness on the desert air" and is yet to take us by surprise I know not, but I see no sign of it as yet. A good one is sometimes overlooked, as in the case of Comte de Raimbaud, a bloom of which exhibited this year took everyone by surprise. The name even does not appear in the catalogues of most of our leading growers, and is, I am told, only to be found with Mr. R. Veitch of Exeter. But if French Roses have disappointed us English raisers have maintained the glory of the flag. Mrs. Laxton (Paul & Son), John Bright (Paul & Son), May Quennell (Postans, sent out by Wm. Paul & Son), and Penelope Mayo (Davis, sent out by Turner), have all proved good Roses. The first especially is one of the finest exhibition Roses we have. I have watched it as it has been exhibited both in pots and as

cut blooms, and under all circumstances it has proved a first-rate Rose. We have some promising Roses also coming forward, but these notes have to do with the past and not with the future. It is disappointing that out of the thirty-six Roses put into commerce last autumn in France no more can in justice be said, but of late years our gains from these have been few.

While the general character of the bloom was below par there were certainly some of the finest blooms exhibited I ever recollect to have seen, and it is very remarkable how certain Roses in particular seasons come to the front. Last year François Michelin was everywhere good, this year I did not see a noticeable bloom. The Rose of the year, and that in a year when dark Roses were not especially good, was in my estimation Reynolds Hole. I am not likely to forget soon the blooms exhibited at Manchester and Preston, a box at the latter show exhibited by Mr. Cranston being one of the most telling exhibits I ever recollect to have seen. Then there were at the National Rose Society's Crystal Palace Show some stands which will long remain in one's memory; the stand of Horace Vernet exhibited by Mr. Cant, wonderful in size and colour; the magnificent stand of Souvenir d'Elise Vardon shown by Messrs. Mitchell & Son, Piltown, the very perfection of a Tea Rose, and with such substance as one rarely sees; the beautiful box of Capitaine Christy by Messrs. Paul & Son, Cheshunt, showing how valuable it is in such weather as we experienced the last week in June; and the stand of Boule d'Or exhibited by Mr. Cant, a Rose which no one seems able to grow as he does—at least not to open its blooms, it being one of those hard-budded Roses which perplex and worry growers.

Nor must it be left unnoticed how much the seedling Briar is taking the place of the Manetti, and along with it Briar cuttings. On all sides I hear of the favour in which it is held; and although its comparative slowness will not make it commercially so great a favourite with growers for sale, yet I am confident every year will see it increasing in numbers. I do not find it liable to the objection sometimes urged against it, throwing up suckers as the Dog Briar of the hedge does, nor underground shoots as the Manetti is so liable to do. A careful excision of the eyes will in both cases greatly prevent it, and I cannot but think that an indigenous stock is much more likely to suit our climate than one brought from the sunny plains of Lombardy. It may be true that this stock is novelty, having been so long used by French Rose-growers for their Teas, but Mr. Prince's name will be ever identified with the extended favour it has met with in England. Others are following in his wake, but he undoubtedly led the way.

It will have been noticed that the fixtures of the National Rose Society have been already made, the first at the Crystal Palace on June 28th, and the second at Manchester on July 14th. Rose-growers are busy preparing for the battle, and if I mistake not we shall, if spared to see it, see such a "gathering of the clans" as has not yet been witnessed. *Vivat Regina!*—D., Deal.

DRESSING CARNATIONS.

As I read the papers by "WYLD SAVAGE" and "A STAFFORDSHIRE GROWER" on the subject of dressing flowers I had forcibly revived in my memory the words of the great apostle, "For when for the time ye ought to be teachers ye have need that one teach you again which be the first principles." "WYLD SAVAGE" entered into the discussion evidently without an elementary knowledge of the laws which govern its practice, and was so deeply in error as to suppose that gum or other extraneous substance might be used; and "A STAFFORDSHIRE GROWER" thinks that unfair and illegitimate which was set up by the first master of dressing (*vide* Hogg: "One Christopher Nunn of Enfield, Middlesex, a noted florist in his day, was eminent for his skill and dexterity in dressing Pinks and Carnations for prize exhibitions. Some will even tell you Kit was father of the art. Upon such occasions he had as many applications to dress flowers as he had to dress wigs, for he was a barber and friseur by trade, and could both shave and lay a Carnation with the greatest nicety"), and thus traverses not merely the unquestioned and unquestionable practice of our fathers, but all the arts of cultivation.

If it be illegitimate for Mr. Douglas to have the help of his friend and the friend of every devoted florist in the length and breadth of the land (Mr. Simonite), it must be equally illegitimate for Mr. Whitbourn to employ Mr. Douglas, for Mr. Douglas to direct the hand of any save himself, and so on and

on until society had ceased. As a matter of fact I can speak of the existence of the practice for upwards of fifty years, that period having elapsed since I first saw a Carnation show, and never before have I heard it questioned. If "A STAFFORDSHIRE GROWER" will put away the vain fear which, as it appears to me, prompted his questioning, and will bring well-grown flowers to the next London exhibition, I will, if spared, undertake to obtain for him such aid in their preparation as will leave him little room for a grumble; but if, declining this, he will only enter into a competition in which, from his point of view, there shall be an equality of power, I ask him, How will he reply to the novice who, coming for the first time to the exhibition table, says to him, "You have been by your own showing a grower and exhibitor at local shows for many years, and have been fairly successful; I commence to-day only, therefore bring the flowers you first brought and dressed as you first dressed them and pit against mine, or I cannot compete upon equal conditions?" Probably the "STAFFORDSHIRE GROWER" would feel and express much amazement at the pretension of the novice, and he must pardon my saying that most experienced florists will regard his proposition with the same feeling.

If Mr. Douglas had been guilty of obtaining illegitimate aid in the preparation of his flowers at the late exhibition of the National Carnation and Picotee Society the complaint should have been made to the executive of the Society, who would know how to deal with and repress irregularity.—E. S. DODWELL, 11, Chatham Terraces, Larkhall Rise, Clapham, S.W.

GARDEN FENCING.

MR. LAXTON asks for suggestions with regard to a cheap, durable, and reasonably safe fencing. As he mentions wooden walls I will venture to give my experience. As the ground has depth of soil I should recommend, if stone is easily to be procured, to place the wooden posts for the fencing on large stones, fastening them by iron dowels, there is no necessity then to use oak; good red deal $3\frac{1}{2}$ by $2\frac{1}{2}$ inches—that is, a 7 by $2\frac{1}{2}$ batten cut in half and set edgewise, is strong enough. Posts to be placed 7 feet apart and boarded horizontally with inch red deal, each board about 7 inches wide, 21 feet long, and not jointed too close, so as to allow for expansion by wet. Use neither paint, gas tar, nor anything to surface the boards for at least two years, and even then it is better to avoid it if possible. I have known an unpainted wood palisading last nearly thirty years, when the posts had quite perished in the ground.

I presume that as the boarding is to be used for protection it is also to be economised as a fruit wall. I put up one six years ago when taking in some extra kitchen garden. Wanting a protection from the north I made the fence 8 feet high, and trained on it Plums. In two years the Plums had covered the boards, and the second year were covered with fruit. This year again the fruit was hanging in ropes. Stays should be placed from every third post—that is, 21 feet apart, sloping to the south, fixing each post in a stone about 5 or 6 feet from the boarding; put a half-rounded top rail $3\frac{1}{2}$ by 2 on the top of the upright posts, and if the position is much exposed board up by means of a top and bottom rail every other stay, so as to break the force of the wind, protect the trees, and make a warm border. I do not think the fruit wall, if I may call it such, which I have made nearly on these measurements is any worse now than when first put up. The trees are trained on galvanised wires.

It is not generally known that the best and most lasting wood for posts is Robinia pseud-acacia, and that even young shoots will last longer than oak or Spanish chestnut. Unless oak is very full of heart it does not last much longer in the ground than a good piece of well seasoned red deal, and the comparative cost of working and the first outlay is great. A good Onga post will last out two larch posts; but if the ground is moist elm is preferable to either, provided all sap is taken off, and the post is well saturated in gas tar mixed with paraffin or creosote with sulphate of zinc. It is cheaper in the end to cut elm posts out of well-seasoned wood rather than use limbs only squared up and put in undressed, as is so often the case with rough oak posts, &c., for common fencing.

If on one side of the experimental garden a protection against cattle is all that is required, nothing is more inexpensive than a well-constructed wire fence; and I may say instead of expensive wrought iron straining posts I have found that 4 or 3-inch cast iron pipes, such as are used for hot water, cut in half, 12 by 9 feet lengths and fastened into large stones with Portland cement, and properly stayed, form as good straining

posts and as cheap as anything that can be used. Two-inch cast iron pipes are enough for most places, but I have had them 4 and 3-inch in the south straining wire fences against covers, and in a park, and have never found them broken by horses or cattle, though a slight 2-inch one in my lower kitchen garden was broken not long ago by a horse being driven against it when playing with another, having been let loose accidentally from a field. But this was in a position where it would not, except under quite unforeseen circumstances, be exposed to such hard treatment. The stays should be of double bars of wrought iron, with an opening for the wires to go through between them, bolted into the cast iron post just under the top wire, and set in large stones. The stone in which the upright post is fixed, and that which supports the stay, should be connected together by means of a strong iron bar leaded into each stone. I am only speaking now of the straining posts; as iron is cheap now the intermediate posts may be of wrought iron. Note one thing, the top and second wire should be strong and hard drawn, and avoid as a rule contract work with wire fence makers; this, perhaps, is a bold thing to say. Should a wire fence be undesirable, and post and rails, or a palisaded fence preferable, split larch, avoiding that which is too young and quickly grown for rails, and good red deal posts, if acacia or Spanish chestnut are not to be procured. But the posts need not be too thick. Let the strength be laterally, so as not to weaken the post too much by making holes for the rails.—C. P. P.

I HAVE put up many hundreds of yards of continuous flat bar fencing which can erect 4 feet high, with five flat and one round top bar, and stand 18 3 feet apart, for about 2s. 3d. per yard, or 5-feet fence for 2s. 6d. This fence—if well painted in two coats of Hill & Smith's varnish, which should not be put on until six months after the fence is erected, and the first black iron scale rusted off—will last twenty years without repair—i.e., mine has. A Holly hedge, or, if speed is required, a Spruce Fir hedge well clipped inside, will afford as much shelter as a wall, and look neat. Or if you wish to make an impervious fence, a good Thorn hedge trimmed 2 feet higher than the iron will keep out an apple-stealing schoolboy, and that is a good deal; or if he gets in he cannot get out again, as you can neither get through nor over (if the Thorn fence is really well done) from the Thorn side.

Every bar of my fence in each standard is keyed, and each bar riveted to the next. If the fence is well put up the heaviest cattle cannot stir it. It is elastic, and stiff as a wall at the same time.—T. J. LEVETT.

MANETTI VERSUS SEEDLING BRIAR STOCK.

YOUR correspondent, "W. C. A.," asks, How is it the Manetti stock has fallen into such disrepute? I answer for myself—and I believe many others will say the same—because I obtain better blooms on the seedling Briar. My soil being naturally thin and hot I excavate beds about $2\frac{1}{2}$ feet deep, putting a layer of stiff clayey soil on the bottom about 6 inches deep, and then fill up with good loam taken from a neighbouring bullock pasture, adding but little manure to the soil at the time of planting, but giving a good mulch of cow and pig manure when the beds are finished. In the spring, about March, this is pricked in with a fork, but not deep enough to disturb the roots of the Roses. I followed this plan with the Manetti for about ten years, but my blooms were always thin and did not stand well in a hot tent. I then heard of the seedling Briar, and sent to Mr. George Prince for a bundle, and they came—grand robust-looking fellows. I subjected them to the same treatment, and my blooms are now much better and have won many prizes this year. If we could only procure the seedling Briar at the same price as Manetti are offered at in your columns I feel sure the Manetti would sink into the shade. I have tried to bud the seedling Briar, but with very partial success, and I prefer sending to Oxford for plants. I wonder whether "WYLD SAVAGE" has ever tried them. I commend them to his notice. Mine have never suffered much from frost. I always plant them just like the Manetti, covering the worked part with soil about 3 inches. Another objection to the Manetti with me was that when I planted a bed I always found a number of gaps in the following year; this has never happened with the seedling Briar.

I have never tried Briar cuttings. Will some of your correspondents kindly tell me how to manage them? Are they budded on the main stem or on the side shoots like the hedge Briar? One thing more about the Manetti. Singular to say

I never could get any good blooms from my maidens. I had shoots sometimes a yard long, but the blooms on the top were ragged and rough and unfit for exhibition. I may have been wrong in my treatment, but I certainly succeed better with the seedling Briar, and the public generally seem to appreciate them, for I happen to know that Mr. Prince has more orders than he can easily execute. I shall certainly discard my Manettis—about two thousand in number—and go in entirely for the seedling Briar; but £50 a thousand is rather a stiff price.—W. H. J.

CHRYSANTHEMUM SHOWS.

LIVERPOOL.

THIS Society held their winter Exhibition in St. George's Hall on the 20th inst., and was in every respect a great success. Notwithstanding the weather being dull and foggy, accompanied by a sharp, cutting, easterly wind, there was never perhaps a greater assemblage of influential visitors seen in St. George's Hall at any former winter exhibition. As a whole the quantity and quality of the exhibits were quite up to the standard of previous years and in many respects much superior. The cut-bloom classes possessed extraordinary interest, owing to an enlargement in the competition, which was produced by the gardeners of Liverpool subscribing about £10, which was offered in three special prizes for twenty-four cut blooms of large-flowering Chrysanthemums, for which seven lots were staged, one being from Wimbledon, Surrey, and another from the neighbourhood of Wolverhampton, but both were nowhere in the race. The first prize was nobly won by Mr. Tunnington, gardener to Charles McIver, Esq., with a stand of neat well-finished blooms; the second prize was awarded to Mr. Peerse, gardener to R. Raynor, Esq.; and the third to Mr. Elliott, gardener to W. G. Bateson, Esq. Mr. Peerse's blooms were probably the largest ever seen, but coarse in comparison with the third-prize collection. The leading varieties in these three stands were Queen of England, Jardin des Plantes, splendid blooms both bronze and yellow; Empress of India, Golden Empress, John Salter, Princess of Wales, Prince Alfred, Emily Dale, Inner Temple, Fingal, Faust, Golden Beverley, Barbara, Baron Beust, Beauty, Mrs. Heale, Lady Hardinge, Nil Desperandum, Miss Mary Morgan, Countess of Dudley, Eve, Guernsey Nugget, Lady Talfourd, White Globe, Sir Stafford Carey, Mrs. Dixon, Beethoven, Isabella Bott, Cherub, and Lady Slade.

In the classes for eighteen and twelve blooms there was a keen competition. Mr. Knott, gardener to C. Coltart, Esq., was placed first in the eighteen, and Mr. Todd, gardener to J. W. Cropper, Esq., was awarded first in twelve. Both stands contained very meritorious blooms, and bore signs of superior culture. Mr. Tunnington exhibited a stand of Japanese varieties of Chrysanthemum, which were much admired, being a new feature at Liverpool.

In trained specimens, either Pompon or large-flowering, there were little or no specialities, all being trained in the old flat style except one lot exhibited by Mr. Hughes, gardener to R. G. Moran, Esq., which were more conical in shape than formerly, and although only being awarded second prize, they were healthy well-bloomed specimens, particularly Barbara, Fingal, and King of Crimson.

Foliage and flowering plants were well represented. In the class for ten Mr. Peerse was placed first, and Mr. B. Cromwell, gardener to T. Moss, Esq., came in very closely second. Stove and greenhouse Ferns were keenly contested. In the class for six there were seven competitors. Mr. Elliott secured first honours and Mr. Cromwell second. Primulas and Poinsettias were numerous and healthy; Roman Hyacinths were very inferior compared with what we have seen at previous exhibitions. In hand bouquets the quantity was great and quality excellent. Mr. Turner, St. John's Market, carried off the first prize, and Messrs. Davis & Co. of Wavertree second.

Fruit was not very plentiful, but the quality was good. For the first prize in Pine Apples there was a close race between Mr. Tunnington and Mr. Jamieson, gardener to the Earl of Balcarris, Haigh Hall, Wigan, but the prize was awarded to Mr. Tunnington; both exhibitors staged very meritorious specimens. Grapes were very good, particularly the fine bunches of Barbarossa exhibited by Mr. Playfair, gardener to H. H. Nicholson, Esq. In the collection of twelve dishes of fruit Mr. McMaster, gardener to W. Just, Esq., was first, and Mr. Mease, gardener to C. W. Neuman, Esq., second. In the class for six dishes Mr. Hinds, gardener to Sir T. E. Moss, was first, his collection including a dish of large highly coloured ripe Strawberries, which reflected great credit on the skilful cultivator.

A decided improvement in the Exhibition this year was the plan of arranging the plants for effect. The stages which at former exhibitions occupied the centre of the Hall were done away with, and a plan composed of five octagon beds was marked out on the floor by wooden edgings 4 or 5 inches high covered with green baize, the centre of each octagon being filled with the largest Ferns and Palms, surrounded with the smaller plants and specimen Chrysanthemums. The effect produced reminded us of

a well-arranged subtropical garden. The Exhibition upon the whole was a great success, and in congratulating the Secretary and Committee we hope their exertions this year will lead to a still more successful future.

KINGSTON-ON-THAMES.

The Kingston and Surbiton Chrysanthemum Society held their Show in the Drill Hall, Kingston, on the 21st and 22nd inst., and we do not hesitate to pronounce it the best show of the season—a great honour, considering that the Society has not been established two years. The Hall, one of the largest structures in Surrey, was full to overflowing. In the whole of the great collection there was not a badly flowered plant or an unsightly flower, consequently many a good exhibitor was unable to command a prize. The arrangements were tastefully and satisfactorily carried out by the Secretary, Mr. Jackson, jun., ably assisted by his coadjutors Messrs. Puttock and Sheppard.

The schedule comprised thirty-seven classes, twenty-six of which were open to all. Prizes were also offered for groups of miscellaneous plants and for collections of Chrysanthemums, which were arranged in semicircles along the sides of the building, while the cut blooms occupied four tables each 40 feet in length, the collections of dinner-table plants being arranged down the centre of each table between the blooms, the whole producing a beautiful appearance: 1164 cut flowers were staged, 250 of which were Japanese blooms, and the brilliancy and softness of colour of the latter far surpassed the effect produced by the incurred flowers.

The miscellaneous groups of plants were arranged at the foot of the orchestra, the prizes falling to Mr. Buckland, gardener to Mrs. Hodgson, Norbiton Park; Mr. Attrill, gardener to C. J. Freake, Esq., Bank Grove; and Mr. Watson, Surbiton, in the order named. In the class for groups of Chrysanthemums Mr. Lyne, gardener to L. Schlusser, Esq., Belvedere, Wimbledon, won the premier place with plants exhibiting very good quality. Mr. Bond, gardener to Mrs. Beckford, Ham, received the second prize; Mr. James, gardener to W. Farnell-Watson, Esq., Isleworth, the third; and Mr. Levesley, Spring Grove, Isleworth, was awarded an extra prize. Seven collections were arranged. For six trained specimens Mr. Beckett, gardener to J. McConnell, Esq., Esher, obtained the first prize with large and well-flowered plants of Venus, Mr. G. Glenny, Mrs. G. Rundle, Hereward, Mrs. Dixon, and Lady Hardinge. Mr. J. Levesley was placed second, and Mr. Cornhill third. Mr. James also exhibited a grand lot in this class which at many shows would have taken a first prize. In the corresponding class for threes Mr. W. Burns, gardener to W. A. Rigg, Esq., Hersham, Mr. R. Watson, and R. Nagle, Esq., were placed first, second, and third respectively; while the prizes for three standards went in the following order to Messrs. Cornhill, Beckett, and Ploughman. Mr. Beckett was first with a single specimen of Prince of Wales, Mr. J. Levesley second with Jardin des Plantes, and Mr. W. Burns third with Mr. G. Glenny.

Pompon varieties were grandly exhibited, and the first prize for six was deservedly awarded to Mr. James for a collection which rivalled the first-prize-and-cup group at the Westminster Aquarium. The varieties were Mdlle. Marthe, Mr. Astie, Mrs. Hutt, St. Michael, Jane Darnley, and Prince Victor. Mr. J. Levesley exhibited well, and was awarded the second prize. Mr. Cornhill was placed third. In the class for threes Mr. Masters, gardener to F. Day, Esq., Oatlands Park, and Mr. Watson, gardener to T. H. Bryant, Esq., were the only exhibitors, and were placed first and second respectively; and for a single specimen Pompon Mr. James, Mr. Levesley, and Mr. Lyne were placed in the order named. For three standards Mr. Ploughman was first, Mr. Cornhill second, and Mr. Lyne third, all exhibiting well.

Cut blooms incurred.—For twenty-four blooms, distinct, the first prize (a silver cup) was awarded to Mr. G. Harding, gardener to T. O. Galpin, Esq., Bristol House, Putney Heath, for a splendid collection consisting of Queen of England, John Salter, Golden Queen of England, Prince Alfred, Empress of India, Mr. Brunlees, Guernsey Nugget, Alfred Salter, Themis, Mrs. Haliburton, Faust, Golden Dr. Brock, Yellow Perfection, Venus, Beauty, Jardin des Plantes, Novelty, Barbara, Mrs. G. Rundle, Princess Teck, Golden John Salter, Lady Hardinge, Antonelli, and G. Glenny; Mr. Hinnell, gardener to F. Davis, Esq. (the President of the Society), was placed second with very fine blooms; and Mr. Reynolds, Weybridge, third. There were eight competitors. A special class was provided for twenty-four incurred blooms, the first and second prize contributed by S. Page, Esq. There were seven collections. Mr. Croxford, gardener to Mrs. Dunnage, Surbiton, and Mr. McPherson were first and second respectively, both exhibiting well. In the class for twelve blooms twelve collections were staged, and Mr. Higgs, gardener to Mrs. Bryant, Surbiton, was awarded the first prize. His stand comprised White Venus, Rev. J. Dix, Prince of Wales, Princess of Wales, Cherub, Lady Hardinge, Golden Beverley, Princess of Teck, Lady Talfourd, St. Patrick, and G. Glenny. There were several collections of six blooms, and Messrs. Beard, Kendall, and Burnett were placed in the order of their names.

Japanese.—These were splendid. Eight collections of twenty-four blooms, all fine exhibition flowers. Mr. Beckett won first

honours with the finest collection that has ever been staged; the blooms measured from 6 to 9 inches diameter, and comprised Fair Maid of Guernsey, Bronze Dragon, Dr. Masters, Grandiflora, Red Dragon, The Daimio, Baron de Prailly, Fulton, Striatum, La Nymph of extraordinary size, The Sultan, Gloire de Toulouse, Red Indian, Meg Merrilees, Fulgore, and Ne Plus Ultra; Mr. Ploughman was awarded second honours with a remarkably good collection; and Mr. Masters third. Several collections of twelve Japanese blooms were staged. Mr. Watson secured the first place, having, among others, a fine bloom of The Khedive; Mr. Jordan was second with a good lot; and Mr. Burns third. In the sixes Mr. A. Nagle, Mr. P. F. Sutton, and Mr. Benson were placed first, second, and third respectively.

The best stand of reflexed varieties was composed of Chevalier Domage, Golden Christine, Garibaldi, Cloth of Gold, Progne, Ariadne, Beauté du Nord, Mazeppa, Mrs. Forsyth, and Felicity exhibited by Mr. Ploughman; Mr. R. Watson was placed second, and Mr. Harding third; and for twelve Anemones Messrs. Masters, Cornhill, and Watson were placed in the order named. Mr. Lyne was first in the class for twelve Pompons, and Mr. Watson second. The principal contributors among the amateurs were Messrs. Drewitt, Nagle, and Sutton, who all exhibited well.

Numerous collections of dinner-table plants were contributed. The first prize was awarded to Mr. Bates, gardener to W. Punchard, Esq., Twickenham; the second to Mr. Jordan, Wimbledon; and the third to Mr. Beckett, all exhibiting collections of high quality. Chinese Primulas, Cyclamens, Poinsettias, and berried plants were contributed by Messrs. Beckett, Beard, Kent, Watson, and Hinnell, who were the principal prizetakers.

Several good collections of fruit were also staged, especially by Mr. Child, Mr. Baker, Mr. Beard, and Mr. Cornhill; and Messrs. Jackson & Son contributed several boxes of cut blooms of Chrysanthemums, principally of new varieties.

GRAVESEND.

The fifth annual Show was held in the Milton Hall on November 19th and 20th. The quality generally of the exhibits presented a very marked improvement on those of previous years, some of the specimens being particularly good. The method adopted of giving prizes according to the number of points obtained, and in proportion to the amount of subscriptions received and money taken at the doors, is worthy of being imitated not only at Chrysanthemum shows, but also at other shows held earlier in the season. It is a well-known fact that many horticultural societies collapse for want of funds. If, however, societies adopted the plan followed at Gravesend this much-to-be-regretted occurrence would be avoided.

The various classes in the Show were all filled. Only in one instance was it found advisable to withhold the first prize. Amateurs showed in a very creditable manner—namely, Messrs. Carpenter, Dunk, and Bardoe. In the gardeners' class for four dwarf-trained large-flowering varieties Mr. R. Phillips, gardener to Capt. Jackson, Meopham, was first with good specimens of Mrs. Forsyth, Mrs. Sharpe, Mrs. G. Rundle, and Gloria Mundi. Had the plant of Venus staged in the second-prize collection by Mr. Lamkin, gardener to J. S. Dismore, Esq., Gravesend, been sufficiently in bloom the positions would have been reversed, his plants of Prince of Wales, Mr. G. Glenny, and Sir Stafford Carey being very superior. Mr. Lamkin was first for two dwarf-trained plants with Dr. Sharpe and Golden Hermione, and also for four standards with Lord Derby, Lady Hardinge, Mrs. G. Rundle, and Mrs. Dixon. For two standards Mr. J. Boulton, gardener to R. A. Gibbons, Esq., Northfleet, was first with Mrs. G. Rundle and Mr. G. Glenny. The single specimen dwarf-trained and pyramid classes were very good. Mr. Lamkin was first in both classes, in the former staging a remarkably fine well-flowered specimen fully 5 feet in diameter of Mrs. Dixon, and in the latter a good plant of Mr. G. Glenny. The same exhibitor was also first for four dwarf-trained Pompons with Antonius, Mdle. Marthé, Cidonia, and White Cedo Nulli, also for a single specimen pyramid. Mr. J. Boulton was first for four and also for two standard Pompons.

There was a good display of cut blooms. Mr. G. Pender, gardener to S. C. Umfreville, Esq., Greenhithe, and Mr. J. Boulton each took three prizes, the former for twenty-four and twelve incurved varieties, among which were good blooms of Princess Teck, Beethoven, Guernsey Nugget, Eve, Empress of India, Prince of Wales, Mrs. Haliburton, &c., and for twelve Japanese varieties; these included fine blooms of Dr. Masters, Baron de Prailly, Hero of Magdala, Alfred Salter, and Fair Maid of Guernsey. Mr. Boulton was first for twelve reflexed, twelve large Anemone-flowering, and twelve bunches of Anemone Pompons.

Mr. Wright, gardener to E. Bryant, Esq., Gravesend, was first for a collection of fruit, consisting principally of excellent dishes of Apples, Pears, and Grapes, and also for three bunches of Grapes, with very creditable well-coloured Mrs. Pince's Muscats. Collections of vegetables were well shown. Mr. J. Pope, gardener to J. Russell, Esq., was first, closely followed by Mr. J. Fielder and Mr. R. Phillips, who were placed equal second. Mr. Beazley exhibited a monster Gourd weighing 84 lbs., and Mr. J. Coombes, nurseryman and seedsman, Gravesend, an attractive group of plants, fruit, and artificially coloured grasses and flowers. The

Show was well arranged, and reflected great credit on the Secretary (Mr. Wright) and the Committee.

MAIDSTONE.

Under the auspices of the Maidstone and Mid-Kent Chrysanthemum and Fruit Club the annual Exhibition was recently held in the Corn Exchange and Concert Hall, and the exhibits, which were numerous, exceeded in point of merit any show that has taken place in the town during the present year. The schedule was a liberal one, and included two handsome cups—one given by Viscount Holmesdale and Sir W. Hart Dyke, Bart., and the other by Major Ross and Captain Aylmer. These were won by the Rev. Stuart Robson, and the silver cup given by the Society was carried off by the Rev. C. Shepherd. There were other exhibitors not far behind the above. These were Mr. S. Davies, F. Pine, Esq., J. W. Braddick, Esq., and R. Whibley, Esq. The specimen plants, both standards and bush-trained, were nearly perfect in every instance, while the cut blooms for size, symmetry, and colour were difficult to surpass; indeed, it must be very gratifying to those who have had the working-up of this Society, which is yet in its infancy, to see their labours prove so successful in the advancement of the cultivation of a flower which has for years been somewhat in the background in the district.

The display of fruits was equal to what might be expected from the county, all being first-class in quality, and contributed a fine feature to the Show. The black Grapes from Lady Mostyn, and the white Grapes from Mr. Douglas and others, were the admiration of all. The Apples and Pears sent by Roger Leigh, Esq., L. A. Killick, Esq., and Mr. Skinner, as well as vegetables by Mr. Killick, were excellent. There was a full complement of miscellaneous plants sent by gentlemen not for competition, which, when interspersed among the stands of cut flowers and fruit, added greatly to the beauty of the Exhibition.

CHELMSFORD.

After a lapse of twelve years the Chelmsford and Essex Horticultural Society have resumed their Chrysanthemum Show, which was held on the 20th inst. The Show, which was a good one, was held in the Corn Exchange and was largely attended. Messrs. Saltmarsh & Sons were the most successful exhibitors, both their plants and cut blooms being highly meritorious. Amongst amateurs Mr. Tunbridge, gardener to W. Bott, Esq., Broomfield; Mr. Kemp, gardener to James Christy, Esq., Roxwell; and Mr. Smale, gardener to Robert Woodhouse, Esq., Writtle, staged very good specimens. Cut blooms of Pompons were not good, neither were the stove and greenhouse plants. Ornamental-foliaged plants were creditably exhibited by Mr. H. Clements, Mr. T. Harris, and Mr. J. Burrell, who secured the prizes in the order named. Mr. Southgate, gardener to Alfred May, Esq., Chelmsford, exhibited excellent fruit, his Grapes being particularly good. Mr. Clements and Mr. Lay, gardener to C. H. Gray, Esq., Chelmsford, also took prizes for Grapes. Of Apples and Pears there was an excellent display. Mr. James Clark, Writtle, exhibited fifty varieties, for which he was awarded an extra prize. Messrs. Saltmarsh & Sons also exhibited (not for competition) seventy-two dishes of Apples and Pears. Mr. Carver, gardener to the Bishop of St. Alban's, had also good Apples and Pears. Mr. P. Edwards and the industrious Committee contributed much to the success of the Show.

GLOXINIA-GROWING MADE EASY—PLANT PITS.

VARIOUS guides and catalogues are occasionally sent to me many containing long lists and cultural directions for growing this attractive plant. Almost invariably it is stated, "Given a sufficiency of heat and success is easy," and what this sufficiency is another puts in these words, "Gloxinias only thrive well with a bottom heat of 65°, going up to 85°," and so on. I have grown a considerable number of plants during the past year, and have proved that no such high temperature was indispensable or even desirable. In the following brief observations I propose to refer to a few varieties, how I grew them, and what has been the result.

Many of my corms were young, some grown from the leaf-stalks of the previous year—none old; principally Aida, purple rose, shading to blue; Duke of Edinburgh, throat bluish purple, shading to maroon; Esperanza, shaded rose; Princess Royal, throat dark blue, with white tube; with Skeltoni and some other distinct colours. Many of them were upwards of 22 inches across, and produced a great number of flowers in succession, some continuing until the middle of November without any extra heat. They were grown in a moist plant pit, which I shall now describe and recommend. The pit is made like an ordinary frame, but has a shelf around it for small and special plants which require less moisture and do best near the glass. It is facing south, and raised behind to catch every ray of sunlight. In summer the shade afforded by this shelf is found very desirable for cuttings and young tender plants. I find Cyclamens, Gesneras, Achimenes, and many allied plants

in their earlier stages during summer and autumn do remarkably well so circumstanced, and consider it the *best* ideal structure for Primulas, Cinerarias, and Calceolarias, I specially mention this shelf convenience because I have not hitherto seen anything similar, and I have proved its utility. The dimensions of the pit should be to suit circumstances—if too deep it is inconvenient to reach, and in winter and spring the plants become too much shaded when every ray of light should be utilised, and if too large the lights would be difficult to move. At the bottom of this pit, for temporary forcing purposes, I placed 6 or 8 inches of stable manure. I say temporary, for the heat from such a quantity will only last a few weeks; but these few weeks generally answer for striking cuttings and raising plants from seeds. The temperature is regulated by raising the lights by means of a graduated ratchet, which I can lock when so raised. In this inexpensive and useful structure I grew the aforementioned fine specimens of Gloxinias, and many other tender plants generally only to be seen in stoves or forcing houses. I attribute much of the rude health of the plants to the presence of ammonia in the atmosphere of this plant pit.

If these few observations will induce any who appreciate this splendid flower to give it thus a trial I feel assured success will be easily attained.
—W. J. M., *Clonmel*.

CARPET BEDS.

INQUIRIES for designs for carpet beds and modes of planting them effectively are so frequent that we purpose—while there is yet abundance of time for preparing plants and making arrangements for next year's display—submitting a few good examples of carpet beds that were so much admired in the London parks during the past summer.

The bed of which a diagram is given was one of the finest of a very excellent series of beds that were arranged in Victoria Park. The bed was probably rendered additionally imposing by its size—between 20 and 30 feet in diameter—but the pattern can be carried out on almost any desired scale. The bed, as all carpet beds should be, was raised nearly a foot above the level of the lawn, and the surface of the bed was raised in tiers or graduated terraces. For instance, the outer groundwork of *Mentha* (10) was nearly level, still slightly sloping upwards to the next groundwork (4) of *Sedum* glaucum, and again raised still higher was the central groundwork of the dark olive green *Herniaria glabra*. These masses of neutral colours were separated by bright dividing lines. Those radiating from the centre, triple lines, represent a row of *Alternanthera* margined with *Echeverias*, and the outside margin *Sedum* glaucum between two rows of the same succulent. The circles (5) in the elliptical groundwork denote *Chamaepuce diacantha*, and the smaller dots (7) *Sempervivum tabulaforme*. The circles (9) in the *Mentha* each contained a fine plant of *Chamaepuce Cassabonæ*. These with the central *Agave* rising boldly above the smooth surface imparted to the bed a very unique appearance, hence they are specially referred to; and the small cushions of *Alternanthera* (8-11) in the *Mentha* had an excellent effect. It will be observed that the greater portion of the plants employed are hardy or nearly so, the only really tender being *Alternantheras*.

THE SEASON IN THE NORTH.

WE are still favoured with a few relics of what has been, on the whole, an excellent season for the florists. With the Grampians in full view, for some time clad in snow, my garden is still dotted with East Lothian Stocks, red, white,

and purple; Pansies, show and fancy; Mignonette, and double Primroses in three colours. To-day (the 18th) I have fair flowers, for the season, of some Roses—Abel Grand, Antoine Mouton, Cheshunt Hybrid, Maurice Bernardin, Souvenir de la Malmaison, and the unfailing "Glory." Homère on a south wall still displays a few blooms. This plant has been laden with flowers throughout the season, and seems determined to be the last to leave the field as it was about the first to enter it.

From no source has more pleasure been derived this year than from Gladioli; all the varieties have flowered, which was not the case last year. The plants, too, have been strong, and the colours well up; but of some varieties the corms are not turning out as could have been wished. Among others are L'Unique Violet, Madame Desportes, Meyerbeer, and Ondine. Of the first I cannot by experience say much, but the second frequently fails; Ondine is false as fair; and of Meyerbeer

Fig. 61.—Carpet Bed in Victoria Park.

- | | | |

| 1. Agaves. | 5. Chamaepuce diacantha. | 9. Chamaepuce Cassabonæ. |
| 2. Echeveria secunda glauca. | 6. Sedum glaucum. | 10. Mentha Pulegium gibraltaria. |
| 3. Golden Pyrethrum. | 7. Sempervivum tabulaforme. | 11. Alternanthera magnifica. |
| 4. Herniaria glabra. | 8. Alternanthera amœna. | |

neither a friend who grows Gladioluses extensively nor I have one sound root. A well-known grower declared one of my spikes to be the finest of that variety he had ever seen. I remember "D. Deal," mentioned in the Journal that Meyerbeer had one season failed largely with him. This is, however, easily replaced, and the satisfaction derived this season from the culture of these magnificent flowers counterbalances a few disappointments and losses. I think that the splendid stands exhibited this year at our northern shows should incite to a more general and extensive cultivation of the Gladiolus.—A NORTHERN AMATEUR.

EUCALYPTUS GLOBULUS.

IN reply to the question of "C. T." on page 368 with regard to the largest Eucalyptus globulus growing in England, I beg to say that the largest tree growing in Cornwall I believe to be at Penjerick. Miss Fox writes that her tree is about 45 feet high, and that it was planted about ten years ago. It seeded this summer, and I send you a small twig of the tree with the seed on it gathered a few weeks ago and not quite

ripe in consequence. I have a tree at Lamorran about 25 feet high four years from seed, and it has withstood two mild winters planted on an exposed hill, which I have found the best situation for these trees. I fear there is a mistaken notion abroad with regard to the hardness of *Eucalyptus globulus*. I have not found it hardy, or nearly so, in Cornwall. Some twenty years ago I received from a friend in Australia seed of all the *Eucalypti* growing there. I raised from it many hundred plants, but found all the Blue Gum died the first really hard winter. One kind, however—I forget which—lived longer, perhaps three or four years, but died when we had an exceptional winter.—J. T. BOSCAWEN.

The conical fruit, produced in the axils of the leaves, is three-quarters of an inch in length and half an inch in diameter, and when cut has a powerful aromatic odour.—EDS.]

VEGETABLES AT MESSRS. SUTTONS' AND CARTER'S ROOT SHOWS.

MESSRS. SUTTON & SONS.—Leaving to others the task of describing in the Home Farm department of the Journal the agricultural produce, I will confine my remarks to the collections of vegetables and Potatoes. Of these there was a very large number, and the quality was of great excellence. In the class for not less than twelve nor more than twenty varieties of Potatoes the first prize was awarded to C. Eyre, Esq. (gardener, Mr. Ross) for a remarkably even and fine collection of the following sorts—Excelsior, Yorkshire Hero, Snowflake, Main Crop, Climax, Garibaldi, Late Rose, Schoolmaster, Scotch Blue, Magnum Bonum, White Don, Ruby, Early Goodrich, Abraham Lincoln, Rector of Woodstock, Beauty of Hebron, Blanchard, Ashtop Fluke, International, and Lapstone. In other collections some other varieties were seen, amongst them Grampian, which seems likely to be a good variety. The prizes for eighteen tubers of Magnum Bonum brought together a very large collection of beautiful tubers. This variety seems to be a very great favourite. It is very prolific, and on most soils a very well-flavoured Potato. Messrs. Sutton exhibited a dish of their new Potato to be sent out next year—Woodstock Kidney, a very excellent Potato as I can bear witness to, having not only seen but eaten it; and this is after all the true test. A Potato may be very handsome like International, but at the same time be utterly useless on the table. Woodstock Kidney is both handsome and good.

There were some excellent entries of vegetables, but that sent by Mr. Wildsmith, gardener to Lord Eversley, was a long way ahead of the others. All the varieties exhibited were excellent samples with the exception of the Cucumbers which were small, and the Carrots which were "grubby." The collection comprised Intermediate Carrot, Sutton's Sulham Prize Celery, American Red Stone Turnip, Brussels Sprouts (Sutton's Matchless), Dwarf Ulm Savoy, Veitch's Autumn Giant Cauliflower very beautiful, Sutton's Dwarf Red Beet, Trebons Onion very pretty, Student Parsnip, Asparagus excellent considering its earliness, and Tomatoes. The second-prize collection was very good and had, besides some of the above, King of Cauliflowers, Snowball Turnip, Colewort Cabbage, Golden Globe Savoy, and Henry's Prize Leek. The collections of Reading Onions (Sutton's) were very numerous and very fine, as were also those of Carrots and Parsnips. Some plants of Prince of Wales Tomato with its golden yellow pods placed along the centre of the tables where the vegetables were arranged had a very pleasing effect. Anything more complete than this arrangement or more conducive to the comfort of all concerned cannot possibly be imagined.—D., Deal.

MESSRS. CARTER & CO.—There was excellent competition for the prizes offered in the classes for vegetables offered at Messrs. Carter's Great Root Show held in the Agricultural Hall, London, November 25th. The quality of the exhibits generally was very superior to those staged last year, the only exception being the class for Onions. For a collection of twelve varieties of vegetables Mr. W. G. Pragnell, Sherborne Castle, Dorset, was first, exhibiting the following varieties in his well-known style—Tender-and-True Cucumber, Improved Spanish Onions, Pine Apple Beet, Imported Brussels Sprouts, Snowball Turnips, Ayton Castle Leeks, Matchless Red Celery, Schoolmaster Potatoes, Carter's Maltese Parsnips, Veitch's Autumn Giant Cauliflower, James' Intermediate Carrots, and Carter's Heartwell Cabbage. Mr. Iggulden, Orsett Hall, Romford, was a good second, closely followed by Mr. Neal, Bampton, Oxon, who was placed third, and Mr. J. Baker, Broad Street, Bampton, Oxon, fourth. Mr. Iggulden's collection included good Trophy Tomatoes, Veitch's Autumn Cauliflower, Snowball Turnips, Musselburgh Leeks, Snowflake Potatoes, Improved Banbury Onions, and Pine Apple Beet. Mr. Neal staged excellent James' Intermediate Carrots, Reading Onions, Vick's Criterion Tomatoes, Heartwell Cabbage, Carentan Leeks, &c.

For a collection of eight dishes of Potatoes there were fifteen entries, some of which, however, were rather inferior, but the class as a whole was a good one. The first-prize collection staged by Mr. J. Pink, Lees Court, Faversham, consisted of good examples

of Snowflake, Breadfruit, Brownell's Beauty, Red Fluke, Early Rose, Carter's Flourball, Ashtop Fluke, and Blanchard. The second prize was awarded to C. W. Howard, Esq., and the third to Mr. C. Ross, Welford Park, Newbury, both staging very good collections. Mr. Pragnell was first for twelve Onions, and Mr. Cave second. An account of the Root Show will be found in the columns devoted to agriculture and other pursuits.

NOTES AND GLEANINGS.

THE meetings and exhibitions of the ROYAL HORTICULTURAL SOCIETY for 1879 have been fixed as follows:—Meetings—January 4th, February 11th, March 11th and 25th, April 8th and 22nd, May 13th and 27th, June 10th and 24th, July 8th and 22nd, August 12th and 26th, September 16th, October 14th, November 18th, December 16th. Shows—Great Summer Show, May 27th to 30th; Whit-Monday popular Show, June 1st; Rose and Pelargonium Show, June 24th.

— WE are informed that the annual meeting of the NATIONAL ROSE SOCIETY will, by permission of the Committee of the Horticultural Club, be held at their rooms, Arundel Street, Strand, on Thursday, December 12th; and the anniversary dinner will take place on the same evening, when the Hon. and Rev. J. T. Boscawen, Vice-President of the Society, will preside.

— IT is with extreme regret that we record the death, which occurred on the 19th inst., of MR. JAMES McNAB of Edinburgh. Mr. McNab succeeded his father as Curator of the Botanic Garden at Edinburgh in 1848—a position which he filled with singular ability. The garden that was for thirty years under his charge has been rendered by the high qualifications of its lamented chief not only essentially instructive but highly ornamental. No one could visit the garden in which Mr. McNab spent the greater portion of his life as apprentice, foreman, and curator, without being struck by the great beauty and splendid cultivation of the Palms and the fine collections of Conifers and Alpine plants. These are living memorials of a man of great zeal and an accomplished scientific and practical horticulturist. Mr. McNab contributed largely to the horticultural literature of the period, and was the means of disseminating much valuable information on a variety of topics. He was born at Richmond in Surrey in 1810.

— MR. HANBURY of Poles writes to us from Bournemouth thus: "I am staying here, and have been much interested in seeing the beautiful specimens of *EUCALYPTUS* which are grown on the Branscombe estate in the neighbourhood. Many of them are 20 feet high and appear to be growing most luxuriantly. They are planted among the Fir trees."

— THE Committee of the ISLE OF THANET FLORAL AND HORTICULTURAL ASSOCIATION, feeling that some acknowledgment should be made to the Honorary Secretary Charles Dobson Smith, Esq., for his able, energetic, and successful exertions in its cause, have commenced a general subscription to present him with a suitable testimonial, and any sums large or small will be thankfully received by G. E. Hannam, Esq., President, Bromstone House, St. Peter's; W. Manser, Esq., Treasurer, The Coves, St. Peter's; Mr. E. Beaumont, The Parade, Margate; or Mr. H. Austin, jun., Garden Cottage, Fairfield, St. Peter's.

— MR. OGLE of Turnworth Gardens submits the following selection of ROSES for ORDINARY GARDEN DECORATION; they include Hybrid Perpetuals, Bourbons, and Teas:—Charles Lefebvre, Gloire de Dijon, Louis Van Houtte, Madame C. Joigneaux, Monsieur Noman, Duc de Rohan, John Hopper, Pierre Notting, Baronne de Rothschild, Caroline de Sansal, Glory of Waltham, Princess Mary of Cambridge, Eugène Appert, Baronne Prevost, Madame Cambacères, Madame Victor Verdier, Jules Margottin, Comtesse d'Oxford, Souvenir de la Reine d'Angleterre, Paul Neyron, Maréchal Vaillant, Star of Waltham, Général Jacqueminot, Annie Wood, Prince Camille de Rohan, Devonensis, La Ville de St. Denis, Edouard Morren, Marguerite de St. Amand, Baronne de Maynard, Géant des Batailles, Souvenir de la Malmaison, Céline Forestier, Beauty of Waltham, Duc de Wellington, and Lord Clyde. The above, our correspondent states, have proved their free-blooming qualities, and with good cultivation will be found all that can be desired for the purpose indicated.

— THE following are the descriptions of the JAPANESE CHRYSANTHEMUMS exhibited last week by Messrs. E. G. Henderson & Son at the Royal Aquarium, and to which certificates of merit were awarded:—M. Delaux, ruby crimson; form of

flower resembling Garnet; good. *Nuit d'Automne*, rosy crimson, reverse of petals pearly white; form of flower resembling *Fulgore*; distinct. *Rosa Bonheur*, very deep rose suffused with magenta; flower large, with round drooping petals. *Père Delaux*, colour bright chestnut; petals quilled at base; flower small, but very bright. These are promising varieties of a rapidly increasing section of *Chrysanthemums*.

— MR. MOULT of Ravensworth Castle recommends the *Tea Rose DUCHESS OF EDINBURGH* as a valuable variety for affording late bloom, which it continues producing for a long time if kept dry. It is found a good companion for *Mrs. Bosanquet* and *Souvenir de la Malmaison*. The two latter Mr. Moulton considers excellent autumn Roses, and their blooms associate well with *Chrysanthemums* for dinner table decoration.

— THE Hon. and Rev. J. T. Boscawen writes that he is glad "WYLD SAVAGE" had called the attention of the authorities of the NATIONAL ROSE SOCIETY to their duty in the matter of the fixtures of the local Rose shows, and suggests that the secretaries of the country Rose shows write as soon as possible to the Secretaries of the National Rose Society, naming the proposed date of their exhibitions, when no doubt some convenient arrangements will be made to suit all parties concerned.

— A GOOD gardener writes—"Mr. Campbell, Superintendent of the SOUTHPORT WINTER GARDENS, may be congratulated on the quality of the productions of the first *Chrysanthemum* and fruit Show which was held there on the 21st and 22nd inst., as both flowers and fruit were of very high quality. Amongst other flowering plants *Epiphyllum truncatum* *Russellianum* was extremely pretty and well flowered; also some pyramid plants of zonal *Geraniums* from the Botanical Gardens, which being so well flowered, they looked as if it might only have been the month of June instead of November."

— CONSIDERING how useful the brilliant old *SALVIA SPLENDENS* is for autumn and winter decoration, it is surprising that it is not grown in all gardens that have conveniences for autumn and winter flowers. No plant than this is better adapted for associating with *Chrysanthemums*, *Palms*, and ornamental-foliaged plants generally. A great advantage possessed by this *Salvia* is that it will flower equally well in a large or small state. A plant exhibited at the Putney Show last week by Mr. Pithers was about 4 feet high and through, and was a mass of brilliant scarlet. It was one amongst others that, we believe, had been planted out during the summer and potted in the autumn—a simple mode of culture that should insure for the plant a place in all gardens and conservatories. It is valuable also for affording a supply of cut flowers for vase decoration.

— WE recently admired a table of ZONAL PELARGONIUMS at Duneevan. This round table when furnished contains 180 small glasses, each containing a truss of flowers, the whole being arranged with great taste by Mr. McIntosh. During the winter this table is constantly rendered brilliant. The varieties grown include all the best raised by Dr. Denny, Mr. Pearson, and other raisers, and the effect produced by the various colours is extremely imposing. The brilliant group is also rendered instructive, for the names are attached to many of the varieties for the benefit of visitors who are not so well acquainted with them as is their patron—the President of the Pelargonium Society, who grows a very complete collection of these eminently useful plants.

— MR. M. TEMPLE writes in the "Gardener" as follows on *LOBELIA CARDINALIS* :—"This old plant, now seldom seen in quantity, has a splendid effect when grown in groups or lines in the herbaceous border. At an old place on the west coast of Wales I observed a number of plants mixed with *Pentstemons*, having a splendid effect. The *Lobelia's* colour is unique, and when used as a back line nothing in its way can surpass its brilliancy. When returning on my homeward journey I called at the gardens of Powis Castle, where I saw *L. cardinalis* in perfection. In the long herbaceous borders (which have such careful attention from Mr. Lee, the intelligent head gardener), this plant is growing in circular groups, at equal distances, of about ten or a dozen plants in each group. The effect is excellent—*Pentstemons*, *Phloxes*, and other contemporary flowering plants are in harmony with the *L. cardinalis*. Circular specimens of *Clematis Jackmani*, at equal distances in this border, were also very telling. The arrangement of these hardy plants on the terraces of this grand old place makes a most favourable contrast with the ordinary

bedding plants, and is much in character with the ancient buildings.

— THE yield of the CALIFORNIAN VINEYARDS for 1875 was about 8,000,000 gallons. That State has, says a transatlantic contemporary, land enough adapted to Grape culture to make as much wine as France, Germany, Hungary, and Spain combined could produce, and there is no doubt among those who have given the subject the closest study that California will in some future time outrank every other wine-growing region in the world. The foot hills of that State, which are held at one-tenth the price of land in France, have a vast productive capacity, and seldom fail to produce a good crop.

FISH IN A GARDEN AQUARIUM.

IN a former communication on aquatics I did not enter at all into the pleasure which possessors of even a small garden may derive from combining the use of the tank, or artificial pond, for their display with the culture of fish as objects of ornamentation or as pets. Both are compatible, while the daily interest of marking the progress and gradually expanding beauties of the plants and flowers will be greatly enhanced by the additional pleasure of noting the habits and history of their living associates. The former subserve the useful purposes of oxygenating the water and forming a pabulum for the aquatic molluscs and insect forms which are food for the latter, and which thus are prevented acquiring an injurious preponderance.

A few dozen of *Paludina vivipara*, a large dark periwinkle-like shell, ornamented with darker spiral bands; of the various species of *Planorbis*, popularly known by the name of Trumpet-shells, but which can be likened more exactly, so far as external form goes, to the extinct *Ammonites*, so common as fossils in the countries formed by the secondary formations; of *Lymnæa*, such as *Lymnæa peregrina*, *L. auricularis*; of *Luccinia putris* (or the amber snail), and of the liliputian freshwater cockle (*Cycas corneus*) will be sufficient if introduced in the spring time, and a little before the fish, to start a stock which the latter will never entirely eradicate.

These may all be readily procured in most of the ditches having access to the Thames, or in small natural ponds in the vicinity of London. They will of themselves afford considerable amusement in watching their development and habits, propagating freely during many months of the year by spawn deposited in gelatinous bands (some of extreme beauty) on the under side and stems of plants, growing rapidly, and dotting prettily in groups of all sizes the sides and bottom of the tank, or clambering about among the submerged leaves; some even, like the *Lymnæa stagnalis*, a large and very common species, which from its voracity is doubtfully worthy of introduction, skating or gliding body downwards along the underneath part of the surface of the water. Numerous insect forms will inevitably introduce themselves, either transported in the supply of water or entangled in the roots and attached mud of the plants which may have been procured from the neighbouring streams and ponds.

Various species of the *Ephemera*, &c., will be noted as having their successive and limited period of rising during the spring time; the burnished and sprightly *Libellula* will emerge and hover over in a beauty strangely contrasting with the hideousness of their larval condition. Water beetles of all sorts and sizes, both in their perfect state and in their transitional larval state; the so-called divers, swimmers, boatmen, and scorpion—all these will be noticed alternately basking and hunting through the water for prey with restless activity. The *Gyrinus natator* will be seen passing its existence in an endless mazy dance upon the surface with its fellows, while the *Hydrometra*, or Water-measurer, skips, skates, and slides over it by the aid of a special provision of floating foot supports with which it is provided. An infinity of *O. Nixæ* or water woodlice of various species, *Entomostraca*, minute bivalved crustacea, and of other minute and almost microscopic forms of aquatic animal life, will rapidly furnish additional sources of food supply to the fish, which are the subject for our next consideration.

The most suitable are the gold and silver carp, the English carp, the crucian carp, the tench, the perch, the gudgeon, and the minnow. The first are so well known that nothing need be said in respect to them; of the others all are easily fed, become tolerably tame, are hardy, will increase in size, and breed in ponds of even small dimensions.

The comparative shyness and tameness of fish are affected

by the amount of shelter they enjoy and the season of the year. The Crucian carp, which love so well to bask under the great Lily leaves during the hotter weather, spend also a large portion of their time beneath any artificial shelter which may be provided, and are in that case more sensitive of observation than they would be if entirely exposed.

Centre pieces of hollow rockery doubtless conduce to the comfort and welfare of the fish, but prevent them from becoming thoroughly familiar excepting for a portion of the year. During the winter the fish are comparatively torpid, feeding little, and only showing in the fairest weather.

With early spring they appear daily, and by the end of May or beginning of June have become perfectly tame, racing eagerly to be fed, and even seeming to show curiosity when the water is disturbed with the hand or otherwise. Now the male may be seen following the female, and the spawn is

Fig. 62.—*Erica exudans* (see page 411).

deposited, not in ribands or bands, but in countless scattered grains, apparently attached to and entangled amongst the filamentous confervæ and the complex leaping of *Cerastophyllum demersum*, &c. The young appear not to take more than a week or ten days in hatching (though on this point I admit that I need further observation), and would soon vastly outstock the capacity of the pond were it not for the havoc made amongst them by their rapacious insect enemies, of which some mention has been made above.

Immediately after spawning the parent fish become less and less-fold, and withdraw more and more from observation as the season advances. The Crucian carp is a handsome golden-yellow fish, and may be readily procured from 6 to 8 inches in length from any of the purveyors for aquariums.

The English carp is in habit much like the preceding, but is less easily tamed and less likely to breed. It can be added when a few large showy fish are required. All the carps thrive best (in addition to such food as they may naturally obtain) on boiled potatoes reduced to a mash; bread is objectionable, except in small quantities.

The tench is a very handsome bronze-yellow fish, somewhat shy, but fond (like the carp) of sheltering underneath broad leaves near the surface. In the winter they nestle right in amongst masses of confervæ or other weed, using it as we might a blanket for protection from the cold.

Both carp and tench thrive much more rapidly under a higher temperature than that of the external air; the former, as is well known, growing to large size in a few of the waters attached to factories in the north and heated by condensed waste steam. The latter I have experimented on myself in a tank of some size enclosed in a greenhouse and heated by hot water pipes to a temperature often ranging as high as 86° Fabr. Tench bred in this house became rapidly tame, darting eagerly forward to be fed, which was done at first with finely grated raw meat, and afterwards with large and small worms. One of these attained the length of 1 foot within fifteen months of being hatched.

The perch is a handsome bold fish, a little impatient of heat and exacting of air supply; with these care must be taken not to overcrowd the pond; they require feeding with worms, tadpoles, or small fry, and when liberally supplied will grow rapidly to a good size, even in a pond of small compass. As an illustration of this I may state that the whole of the perch now stocking so abundantly, and with fair fish, many of the Australian lakes and rivers were bred in the course of a few years from the descendants of fish exported from England a few inches in length, and raised in a small pond not exceeding 12 feet in the square in the garden of an enthusiastic pisciculturist, Mr. Allport of Hobart Town. These reached in the course of a year or two as much as 1 lb. and 1½ lb. in weight, and the rapid increase of their progeny may be inferred from the statement made some time back in Australian papers that several tons weight had been taken in one season by angling in the large lake adjacent to the town of Ballarat.

Gudgeons breed freely, but the adult fish are shy and rarely show. The small fry coast about during the first season in shoals near the margin of the pond, and are amusing from their vivacity. These, like perch, require frequent partial changing of the water during hot weather, which is easily effected when a tap is laid on. All the other fish can be retained in the same water without change all the year round provided that an abundance of plants are grown.—J. P.

SKIMMIA OBLATA.

RECENTLY in Mr. Shaw's nursery at Bowdon I had the pleasure of noticing a few small plants of this ornamental shrub in fine berry. They were not more than 6 inches high, each having three or four shoots. At this size the plants were extremely effective, and would be valuable for table decoration or for the front row in a show house. *Skimmia oblata* has very fine bright berries; they are much larger in size than those of *Skimmia japonica*—more like the *Aucuba* in that respect, and the berries are closer together in the head than they are on *japonica*. Anyone desirous of working up a select stock of berried plants for table or other purposes of decoration should, I suggest, include this plant in their list. There is also a variety of *S. oblata* with fine variegated foliage, which if well berried would have a pretty and novel appearance when in good form.—R. M.

OUR BORDER FLOWERS—CENTROCARPHA GRACILIS.

AMONG our many beautiful hardy perennial border flowering plants I have one under the name of *Centrocapha gracilis*. The plant is possessed of very attractive properties, is of good habit, attaining the height of 2 feet or more under some circumstances, and when established is very beautiful. At a distance it is one of the most telling plants I know of for open spaces in the shrubbery or any other place, but it must have light and air for its development. It will endure a good deal of rough usage and a considerable amount of drought without any apparent injury. It is perfectly at home in the herbaceous border.

I have an impression that it might be turned to good account for vases or pots for plunging in places where single specimens are required. Our plants commenced blooming in August and continued in great beauty until the November frost put an end to their beauty. They were admired by all who saw them. The ray-florets are a beautiful orange colour, the disc black, which is a fine contrast. It continues long in flower, and is

useful both for cutting and for exhibition. It thrives in ordinary garden soil, having a preference for good loam and efficient drainage. It is readily increased by division in the spring or autumn. It is the only plant I know under this name, but I am not able to find the name in any of the leading catalogues. I should esteem it a favour if you can inform me if it has a synonym.—*VERITAS*.

[*Centrocapha gracilis* is a North American herbaceous perennial, growing about a foot high. Some of the *Centrocaphas* are synonymous with *Rudbeckias*, and your plant is probably *Rudbeckia gracilis*.—*EDS.*]

CAPE HEATHS.—No. 11.

NOVEMBER.

THIS dull month does not favour the opening of many fresh kinds of *Ericas*. We have, however, the bright blooms of

Fig. 63.—*Erica pellucida*.

E. gracilis still to form a pleasing contrast with the white and sweet-scented *caffra*; then again the ever beautiful *hyemalis* is now bursting into beauty. *Mutabilis* also begins again to put forth its bright flowers, whilst *tubiformis* seems to have re-awakened, and is now gay with its second crop of blooms; others, such as *taxifolia*, *grandinosa*, *verticillata*, *curviflora*, *lutea*, *colorans*, and *nitida*, are still yielding a supply of flowers, so that even now this family of plants can still hold their own amongst the pets of the greenhouse.

We have now the whole of these comfortably housed, and all we have to do whilst in their winter quarters is to keep them in a fresh free atmosphere, carefully watering them as they require it, to retain any that may have grown out of order, adjusting the shoots of those inclined to ramble, and keeping a sharp look-out for mildew, so that it does not gain a hold and work its mischief before detection. The following may be added to the list of kinds which bloom about this season:—

Erica evandans (fig. 62, page 410).—A showy kind having linear-obtusate leaves, which are hairy and of a clammy nature, arranged in fours, and dark green. Flowers terminal on the

small branches, mostly in fours, cylindrical, slightly curved, red; style exserted.

E. decora.—A pretty species. Leaves arranged in sixes, linear-obtusate. Flowers axillary, forming a long spike, bell-shaped, ribbed, light purple.

E. pellucida (fig. 63).—Leaves arranged in fours, bright green. Flowers in fours, in closely-set terminal bunches, clear white.

E. discolor.—Leaves arranged in threes, linear, smooth, and bright green; habit erect. Flowers terminal, in threes, tubular, red and green.

GARDENING AT CYFARTHFA CASTLE,

MERTHYR TYDVIL.

CYFARTHFA CASTLE is situated close to the greatest commercial centre in South Wales, Merthyr Tydvil. The elevation is some 700 feet above the sea, and in going up the valley from Neath to Merthyr some of the grandest scenery in South Wales may be seen, as the whole length of the valley abounds with mountains, woods, and rugged streams; but the scenery around Merthyr itself is not very attractive unless it is the monster iron works (now unfortunately at a standstill), belonging to the respected proprietor of Cyfarthfa. The garden, however, will well repay anyone going a long distance to see, as Vines, Pines, and Peaches are more extensively cultivated at Cyfarthfa than any other place I ever saw.

The fruit houses are about three dozen in number, and most of them are large, some of the vineries being over 100 feet in length and 20 feet wide. Some of the Pine stores are about the same size, and the Peach houses are still larger, one, if not more of them, being about 150 feet long. Respecting the Vines, a house has been erected specially for nearly every kind of Grape in cultivation; other houses are planted with all kinds of Grapes together. In this way the merits of all have been, and are, thoroughly tested, as particular treatment when necessary can easily be given to any kind of Grape by having it in a house by itself.

Black Hamburg has come out well under all kinds of treatment, consequently it is grown extensively. Vines in pots of this kind fruit in March, and Grapes are cut from the earliest vinery in April. Many of the Vines had been cleared of their crop at the time of our visit, but one span-roofed house particularly attracted our attention. The borders belonging to this house are inside; the Vines were rooted from eyes in the spring of 1877, and planted out in the borders about the month of July of the same year. This "planting in a growing state" seems to have agreed with them, as they made such strong canes up to the very top of the house last autumn that Mr. Battram did not cut them back at all, but left them as fruiting rods. The crop these have produced this year is still hanging, and a better crop of Hamburgs we never saw on Vines of any age. The four and five bunches on each Vine will average quite 4 lbs. each, and they are perfectly finished in every respect; many bunches of equal size were cut off, as Mr. Battram does not practise heavy cropping for a year or two, and crippling or killing the Vines, and throwing away and planting again. Indeed, the very opposite to this appears always to have been practised, as the majority of the Vine rods appear to be old. Mr. Battram attributes his success with these young Vines and all others more to abundant watering at the root than anything else, but no doubt this must be much assisted by the great attention given to all operations it is necessary to perform during their period of growth.

Muscat of Alexandria is next to the Hamburg in quality. Some houses filled with this fine Grape were perfect pictures to look at; not a single defect in "setting" could be detected in hundreds of bunches, and the form of the bunches and their colour were quite faultless. When thus cultivated Muscat of Alexandria is one of the noblest of all Grapes, but it is not the finest white Grape at Cyfarthfa; that honour must be awarded to Canon Hall Muscat. This is one of the parents of Golden Champion, and as fine a Grape to look at in size of berry, &c., but like its progeny the Canon Hall is not without its faults in the hands of many cultivators. The great difficulty is to induce it to set well and to swell evenly. Canon Hall Muscat is only grown as a single rod in many places, and not at all in others. At Cyfarthfa, however, there is a large house chiefly devoted to it, and it is cultivated to a state of perfection which I never saw equalled. The bunches were about as well furnished with berries as the finest formed bunch of Black Hamburgs, and the berries were of fine size and

colour. Its cultural requirements do not differ from that given to ordinary Grapes; it is only in "setting" it well that the whole secret to success lies, and this Mr. Battram overcomes through carefully fertilising the flowers. Anyone acquainted with this Grape will have observed that when the flowers are just ready for opening a little globe of glutinous matter holds the stamens together at the point. It is when the flower is held together in this way that the berries do not form, and it is by carefully brushing off these little globules with a feather that the berries form so well.

Gros Colman is grown in quantity, but its appearance is more favourable than its qualities, unless it is ripened early and allowed to hang late. Black Alicante is also grown extensively and well, and so is Lady Downe's; the bunches, berries, and indeed the whole crop of which was extremely fine. Duke of Buccleuch was planted on its first appearance in public, but although it has been tried with every attention in several houses it will neither grow nor fruit freely, and it is now put aside as a variety not worth extending. Golden Champion has been placed on the same list, but neither of them will be much missed with Canon Hall so fine. Madresfield Court has done well from the first, and Mr. Battram thinks very highly of it as a summer and autumn Grape; a quantity of it was hanging that had been ripe for a considerable time, yet it showed no signs of decay, and a few berries we tasted were quite firm. Most of the early Pine borders are inside, consequently no fermenting material is used at starting time, and it is considered that even with the borders outside this is unnecessary when the Vines are in good health. None of the borders are mulched or covered up at any time, but great quantities of water are given, and the surface is kept clean, free and open at all times. The strong wood, clean foliage, and heavy well-finished crops all indicate that this treatment may be strongly recommended. All the Grapes were remarkable for their fine bloom, the result of care being taken that the berries are not touched during thinning or rubbed afterwards. Many Vines in pots which were struck from eyes in the spring of 1877 were bearing about 12 lbs. of fine fruit each. Most of the kinds planted out are fruited in pots to fill up spare corners, and a few dozens are started early to fruit in March before the late ones are finished.

A stock of 1500 Pines are kept up, and about half this quantity fruit every year. Large houses are set apart for each kind. One house full of Black Jamaicas were all in fruit at different stages of development; 3, 4, and 5 lbs. is the general weights these attain, and for winter use it is considered the finest flavoured Pine extant. Many housefuls of Queens were coming forward for next spring and summer fruiting, and the fine state of the plants gave great promise of a heavy return. Some of the Providence and Black Prince varieties were bearing fruit 10 lbs. in weight, and Mr. Battram showed us photographs of former fruit weighing 11 and 12 lbs. It is indeed a gratifying sight to see such magnificent fruit. Many of the plants are grown in pots, and many are planted out in beds. Good yellow loam mixed with a little manure is what they are grown in, and after they are come into fruit guano water is plentifully supplied.

We were rather late for seeing the Peaches at their best, but the crops of former years were magnificent, and the trees are in as fine a state of health as ever they were. Figs bear great crops; the trees are planted out in the centre bed of a large span-roofed house. Winter Cucumbers are clean, healthy, and fruitful in pits, and Melons are grown in large quantities in low frames in the middle and end of the season, and in little span-roofed houses earlier.

Besides such quantities of fruit there are many large plant houses and frames containing choice collections of indoor plants all in fine health and growing luxuriantly. One very large house of Heaths is particularly noteworthy as containing such specimens of all the leading kinds of these fine plants as one has seldom the pleasure of seeing.

Out of doors the vegetable crops all looked well, but Cyfarthfa is not a place for fine shrubs. No kinds of Roses do well in the open air, and the choicer kinds of bedding plants do not succeed well either. The Pampas Grass was growing luxuriantly, however, and one of the houses in Merthyr was beautifully covered with the coral-berried Cotoneaster. It is surprising how all kinds of fruit and plants are brought to such perfection under glass in such a situation; it certainly proves that Mr. Battram is a master of his calling. It must be stated that through the much-lamented ill health of the proprietor the garden has lost its chief supporter and some of the

houses are in a dilapidated state. Let us hope, however, everything connected with this great garden may soon be restored and placed on an equal with the productions which few can have seen equalled and none surpassed.—M.

ROSE ELECTORS.

I MUST thank Mr. Hinton for his remarks in his "Rose Olla Podrida" upon what I have recently said in the *Journal of Horticulture*, but he has quite misunderstood me if he thought I wished to have an election of electors. I only want one amateur—say Rev. S. R. Hole, as President of the National Rose Society—to name six nurserymen, and let Mr. W. Paul as a non-exhibitor, or Mr. Charles Turner, name six amateurs who shall be noted exhibitors, and who are well known as competent authorities especially in the matter of new Roses. Many amateurs cannot afford space nor money nor time to try the newer Roses; yet with our past experience, and when we look back on the recent acquisitions of late years, it is to the interest of all rosarians to have some competent verdict on the newer introductions. Why I want both amateurs and nurserymen, and only a dozen, or say a baker's dozen, is that the raisers of Roses are too fond of their own children, and yet practical nurserymen have more varieties pass under their notice than amateurs, and have comparatively more opportunities of observation; though I say again that the amateur, with a more discriminating taste and judgment, and who rides perhaps only one hobby, is more disposed to make an impartial judgment, than one whose trade interests are at stake, and who must have many branches of his profession to carry on.

After Mr. Hinton's experience in the qualities of electors I would venture to lay before him, or say a meeting of the Committee of the National Rose Society, the names of twelve electors—half amateurs and half nurserymen—whose decisions would be accepted, and who, I think, would be willing to act. I am very glad to find that in nearly all points we are so much in accord.—C. P. PEACH.

DOES THE MANETTI THROW UP SUCKERS?

I ADD my testimony to the Rev. C. P. Peach's remarks on this subject. I do not remember to have seen a genuine root sucker attached to the Manetti, but have seen plenty of shoots from the stock, caused, I have no doubt, by careless people leaving the eyes in.

I have looked over all that have been prepared by myself or by the young man who assists me in this work, and there is not a sucker or shoot of any kind to be seen, while on looking over a flat of three thousand stocks budded this season which were bought I see numbers of shoots from the bottom of the stocks, and am convinced they are all from eyes that have not been properly cut out.

Is not the Rev. W. F. Radclyffe joking when he names six of our most vigorous Roses as growing well on the seedling Briar? What stock will not such Roses grow well on?—F. BOYES, *Beverley*.

WORK FOR THE WEEK.

HARDY FRUIT GARDEN.

THE early pruning of bush trees, such as Gooseberries, Currants, &c., as well as Apple, Pear, Plum, and Cherry trees, is desirable. The sooner such work is done after the leaves fall the more expeditiously it is performed. There is often, however, considerable damage done by birds, and where these are numerous and of a kind likely to prey upon the buds it may be a lessening of anxiety to defer pruning until spring, in the hope that there being more buds in an unpruned tree or bush than one pruned, there is likely to be more buds left on the former than latter. Unfortunately the birds appear to relish the plump fruit buds, not caring for the lean buds so long as fruit buds are obtainable; therefore it is questionable whether late pruning preserves the fruit buds and crops. Our experience is the other way, and we can only preserve the buds from bullfinches by employing the gun, it being astonishing what an extent of mischief a pair of these birds can effect in a short time. Pruning may be stated to consist in cutting off certain shoots or branches of a tree for the purpose of modifying its form, increasing its fertility, or stimulating particular parts to increased vigour. It is difficult to give instructions suitable alike for pruning all descriptions of trees, the difficulty being increased when dealing with those having little gardening experience. Generally we may say that Apples and Pears grown as pyramids should not be allowed to become too thick, not only as regards the spray but also the main branches, as the fruit buds require to

be freely exposed to light and air, the fruit attaining to fuller perfection when fully exposed. All the spray should be cut back to within an inch of its origin, presuming the shoots to be several inches in length, but if they are not more than an inch or two long they must not be shortened, as, though they may not be terminated by a fruit bud, such stubby shoots usually form spurs. The branches should be 12 inches apart, and in the case of trees not fully formed the lead should be cut back to 12 inches of the current year's growth, and the extremity of the side branches to about 6 inches, more or less, with a view to the symmetry of the trees. In the case of bushes it is best to allow them to carry strong branches from the base to the top, spurring or cutting in the side shoots so as to leave three buds or so, keeping the centre of the tree open. Plums and Cherries may be similarly treated. The best practitioners are averse to pruning in frosty weather. In making a cut the knife should pass through the wood close to the eye, leaving no portion of wood to die back. After pruning the surface soil may be scraped off and a top-dressing given of turfy loam and decayed manure in equal parts, or if the roots are near the surface a mulching of partially decayed manure may be given. There should be no attempt at digging or disturbing the roots, but rather make the surface firm if at all loose by treading it. Gooseberries and Currants should have all the side shoots cut back to within an inch of their base, keeping the centre of the bushes open and the branches from 9 to 12 inches distance apart. Full-sized bushes may have the leads spurred-in, but those admitting of extension may have the terminal shoots left from 6 to 9 inches in length according to their strength, and judiciously placed for the formation of the bushes. The soil may then be removed from around the stems to the extent of about 18 inches and down to the roots, and be left so for a few (three) weeks if the trees have suffered from attacks of caterpillars, then filling in with well-decayed manure, the spaces between the rows being manured and dug in, but not so deeply as to injure the roots. If the trees grow very vigorously prune less closely and omit the manure. Black Currants must not be spurred, but have the old wood well thinned out, encouraging the young growths. They, too, should have a good manuring, merely pointing it in near the stems, but somewhat deeper in the centre of the spaces between the rows.

FLOWER GARDEN.

All winter and spring bedding ought now to be finished, and the walks, edgings, and turf put in proper order for the winter. Beds or borders that are to remain unoccupied through the winter should now be manured and deeply dug or trenched as may be required, so as to afford the soil the full benefit of exposure to frost. This more particularly applies to ground intended for Hollyhocks, Dahlias, Gladioluses, &c., during the ensuing season. Gladioluses of the *Ramosus* section plant now 4 to 6 inches deep; Turban Ranunculuses plant 2 inches deep and 6 inches apart; also Anemones, except the choice varieties, which are best planted in early spring. The planting of all kinds of trees and shrubs should be pressed forward whenever the weather is favourable, avoiding work of this kind in very wet or frosty weather. Levelling, taking up, and relaying turf, with the making of new walks and alterations generally, should be proceeded with as rapidly as possible. Box edgings may now be replanted, but avoid cutting the Box, or it will be browned by frost. Keep leaves raked or swept up as they fall—a tiresome process, but one that pays from the value of the material for heating and compost-forming purposes. Admit air abundantly to all bedding plants in frames or pits whenever the weather permits, removing all decayed leaves, as at this season damp is the worst disaster befalling these plants. Great care is required among Echeverias, being careful not to over-water them; indeed these and all succulents should be kept near the glass, and as dry as possible without shrivelling. Agaves will exist a long time without water, but their leaves are not so long-lived as when water is duly supplied. Seeds of succulents, such as Echeverias, &c., may now be sown; also Centaureas, Acacias, Chamæpices, and others requiring a long time to make good plants for next season's bedding, they succeeding in a warm house, keeping the pots near the glass after the plants appear, watering carefully, or the seedlings will damp.

FRUIT HOUSES.

Cucumbers.—Cold weather necessitates sharp firing, which where there is little piping dries the atmosphere more than is good for the foliage, the fruits becoming stunted and swelling indifferently, and when the pipes are in close proximity to the roots the soil is dried too much for healthy growth. One of the greatest evils in all houses requiring to be kept at a high temperature is too little heating surface, the water requiring whenever the weather is severe to be kept up to near boiling point. Be careful in giving air, affording it, however, whenever a favourable opportunity offers, but exclude it when the external air is sharp and cold. In bright but cold weather turn off the top heat when the sun is powerful and likely to raise the temperature beyond 80°, in such weather damping the house morning and afternoon, closing early. Care must be exercised in damping so as not to wet the embryo fruits, or they will damp off. Water will be required at the roots about twice a week. A temperature of 60° to 65° at night and 70° to 75° by day is suitable. The winter fruiters or plants from

the August sowing and planted out in late September will have grown to the extent of the trellis, or nearly so. Unless there is undue vigour in the plants they should not be allowed fruit for a few weeks. Attend frequently to the stopping, thinning, and tying of the shoots, avoiding overcrowding and overcropping as the two greatest evils, subduing canker with quicklime well rubbed into the parts affected, removing every decayed leaf promptly. If mildew appear dust with flowers of sulphur, it being well to dust some over the leaves with a view to its prevention.

PLANT HOUSES.

Greenhouse.—If Lilioms have not been potted they should be attended to without further delay, as the early-flowering sorts—*L. auratum*, *L. speciosum*, and *L. longiflorum*—will by this time be pushing fresh fibres, and great injury results if these are disturbed. Potting, therefore, should be done so soon as the stems have died down. Remove the top soil down to the bulbs and any loose soil from amongst the roots, removing the drainage, and if increased pot room is required afford it, but avoid over-potting, it sufficing in most cases that the bulbs be returned to the same sized pot as before, clean and fresh drained. Place the bulbs sufficiently deep in the pots as to admit of the roots which form on the stem being covered with fresh rich compost in spring. About a fourth of the depth of the pots will be sufficient for that purpose. Good turfy loam with a third of well-decayed manure or leaf soil and a free admixture of sand is suitable. The pots may be plunged outdoors in a sheltered situation and be covered about 6 inches deep with cocoa refuse, but are preferably wintered in pits or frames. The soil should be kept moist, but avoid heavy waterings until the tops appear. If kept in a greenhouse assign them the coolest part. Lachenalias keep near the glass so as to prevent their foliage being drawn and to bring out the leaf-markings. All dwarf-growing plants should be kept as near the glass as practicable, and every opportunity should be taken of affording ventilation, giving no more water than to prevent flagging in the case of plants at all liable to damp-off, such as Primulas, Cyclamens, &c., but when the soil becomes dry water it thoroughly—dribbles are dangerous. Where it is desired to keep up a good display of bloom the temperature should be kept at 50° by day and 45° at night. Tuberous *Tropæolums* require to be kept near the glass and to have their shoots regularly trained, for if at all neglected they soon become an entangled mass. The bottom of the trellis must in all cases be well covered with the young shoots before they are allowed to ramble to the top, or there will be great difficulty in covering the lower part. Be careful in watering; the soil must be moist but not wet. Nothing contributes more to the appearance of plants than clean pots and clean surface soil. Fumigate upon the first appearance of aphids, and dust with flowers of sulphur any plants infested with mildew. Chrysanthemums will in many instances be plentifully furnished with suckers. The strongest should be taken off when from 2½ to 3 inches in length and with a small portion of root-stem. These should be inserted about half their length singly in 3-inch pots in a mixture of turfy loam, and a fourth of leaf soil, and a sixth of sand, watering and placing them in a cold frame, where they will root slowly but surely if kept moist to prevent flagging by exposure to bright sun. Afford protection in severe weather, avoiding anything approaching to coddling, and the plants will then be sturdy instead of drawn and weak.

Where large quantities of forced flowers are required a house or roomy pit should be set apart for the purpose, for where forcing has to be carried on in stoves the necessary conditions of light, air, heat, and moisture cannot be afforded the forced plants without interfering with the general stock. A low, light, well-ventilated house is particularly useful at this season of the year for forwarding such plants as *Azalea indica* vars., greenhouse *Rhododendrons*, *Bouvardias*, Tree Carnations, Pinks, Callas, *Daphne indica*, Cyclamens, and many others that require the temperature of an intermediate house to enable them to produce their flowers through the winter months. Abutilons and Zonal *Pelargoniums* require for continuity of flowering a house with a temperature of 50° to 55° by artificial means, with an advance to 65° by day.

TRADE CATALOGUES RECEIVED.

James Yates, Underbank, Stockport.—*Catalogue of Bulbs and Flower Plants.*

A. M. C. Jongkindt Coninck, Dedemswaart, Netherlands.—*List of Coniferae and Fruit Trees.*

Hippolyte Duval, à Montmorency (Seine et Ouse), France.—*General Catalogue of Roses.*

L. B. Case, Richmond, Ind., U.S.A.—*Botanical Index and List of Plants.*

TO CORRESPONDENTS.

* * All correspondences should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

NATIONAL ROSE SOCIETY (C. J. D.).—Write to the Rev. H. H. D'Ombraim, Westwell Vicarage, Ashford, Kent.

ROSES IN VINERY (R. T.).—There is no foundation for the statement that "Roses will communicate disease to Vines and plants." If the Roses are neglected and are permitted to become infested with aphids the insects will certainly spread to other plants, as they appear to have done in the case of your Calceolarias; but by judicious syringings and occasionally fumigating the house all the occupants of the structure may be kept healthy provided generally good cultivation is exercised. The Calceolaria leaves sent are slightly affected by insects. The plants have probably been kept in a too dry atmosphere during the early autumn months. Keep them free from insects and the roots active, and the plants ought to recover. The publication of this reply has been accidentally delayed.

RASPBERRY CANES (E. G.).—The Fastolf and Yellow Antwerp. Any nurseryman can supply them.

COKE FUMES (T. Ballard).—We do not know of anything that will absorb the fumes of coke burned in a hothouse. Troughs of water would absorb a little sulphurous acid, and quiklime some of the carbonic acid, but not so thoroughly as to preserve the plants from any injury.

DISSOLVING BONES (H. K. M.).—1 lb. of bones, 12 ozs. of oil of vitriol, and 12 ozs. of water mixed and left for twenty-four hours.

ERRATUM.—In the notice of Holey Hall on page 391 it was inadvertently stated that the houses were heated by Messrs. Walker & Emley instead of by Messrs. Dinning & Cooke of Percy Street, Newcastle, hot-water engineers of established reputation in that town.

ADDRESS (Mr. B., Liverpool).—Write to No. 3, Westminster Chamber, Victoria Street, London, S.W.

COTTAGE GARDENERS' DICTIONARY (P. Inghald).—You must write to the publishers, Messrs. Bell & Daldy.

PREPARING GROUND FOR ROSES (A. H.).—We should trench the ground quite 18 inches deep, turning in the turf, chopping it in pieces as the work proceeds. It should not be nearer the surface than 6 inches. Break up the subsoil deeply, but do not bring much of it to the surface. If the soil is good it ought to produce very fine roses.

LEAKAGE IN GREENHOUSE (Idem).—If during a dry day you rub some putty firmly between the squares from the outside, finishing it off smoothly, it will speedily set, and we think stop the leakage. When partly set the putty protruding on the inside of the house can be removed with a sharp knife.

ROOT-PRUNING FRUIT TREES (J. B.).—The best time for root-pruning is the present month. The best method depends on the condition of the trees and the skill of the operator. If you have had no experience in root-pruning, the best method for you to adopt will probably be to dig exactly half round the trees, as if commencing to dig them up, undermining them quite to the centre and cutting off the strong roots smoothly with a sharp knife at a distance from the trees of from 2 to 3 feet, according to their size. If that does not check their luxuriance sufficiently the other half of the trees can be treated in a similar manner next year. In replacing the soil round the roots press it rather firmly, selecting dry weather for doing the work. We do not approve of excessive root-pruning in the case of very small trees. If the branches of trees are sufficiently thin that every leaf can have light, fruit spurs usually form without the roots being greatly mutilated.

PLANTS UNHEALTHY (J. T.).—We think the plants were placed in the new house too soon and have been injured by the paint. Paint on the pipes is not injurious when it is perfectly set and sweet. With careful attention and good cultivation your plants will improve, and such others that are introduced now may be kept in good health.

EUCALYPTUS GLOBULUS (G. H. V.).—It is not at all unlikely that the tree to which you refer is *Eucalyptus globulus*. We know of several trees in the southern counties 18 feet high, but they would not have been so high had the two last winters been severe instead of mild. The leaves are only tinted with blue when in a young state. As the tree attains age the foliage changes both in form and colour. The leaf you have sent is very small.

STOVE (W. D. P.).—We are not in possession of information enabling us to answer your questions relative to the stove referred to being withdrawn from sale.

MUSHROOM BED NOT PROFITABLE (Inquirer, Manchester).—If the bed is really dry you had better give it a thorough watering with tepid water, and when the surface has become moderately dry cover it 4 or 5 inches thick with soft hay. The hay should be moved frequently to prevent its adhering to the soil. Apply the water at a temperature of about 85°.

WINTERING TYDEAS (Kittie).—Considering that you have only a greenhouse you have ordered the Tydeas, Gesneras, and Nægeliass too soon. You had better place the tubers in dry sandy soil, yet not absolutely dust dry, and place the pots in a warm position of your greenhouse. In the spring, when the temperature increases so that the house can be kept at about 60°, apply water sufficiently to keep the soil moderately moist, and as soon as signs of growth are apparent the tubers may be potted in a compost of peat, loam, and leaf soil in equal parts. You may place them singly in small pots, or three or more in pots of larger size. They are stove plants, but will thrive in a warm greenhouse. A heated cucumber frame would be of great assistance in starting them into growth in the spring. You will be fortunate, however, if you preserve all the tubers through the winter. Syringe the pots occasionally to prevent the soil becoming excessively dry, or the tubers will shrivel; if, on the other hand, it is too wet they will decay.

FERNs FOR ENTRANCE HALL (A Twenty-five-years Subscriber).—No plants endure so well as Palms, Aralias, Dracenas, foliage Begonias and other plants with persistent foliage. Ferns suitable for your purpose are *Blechnum occidentale*, *Doodia aspera monstrosa*, *Asplenium diversifolium*, *Pteris serrulata*, *P. serrulata cristata*, *P. cretica albo-lineata*, *Polypodium pectinatum*, *Phloxipolepis davallioides*, *N. pectinata*, *N. tuberosa*, *Platyloma Brownii*, *Pteris umbrosa*, *Lastrea decomposita*, *Cyrtomium falcatum*, *Adiantum*

formosum, *A. cuneatum*, *A. assimile*, *Asplenium præmorsum*, *Nephrodium molle corymbiferum*, *Lomaria gibba*, *L. Patersoni*, *L. L'Herminieri*, and *L. discolor bipinnatifida*.

CHARRING HEDGE TRIMMINGS (B.).—The only way to form them into charcoal is to stack the trimmings, forming a pyramidal pile, and cover it with turves both at the sides, ends, and top, the wood being laid moderately loose so as to admit of the fire passing through the whole, having openings at the sides for lighting, which should be charged with dry material, and a few openings at the top to ensure the necessary draught. When the fire is well going it is necessary to see that it does not break through, the holes at the top being closed, and when the whole is charred to the centre of the wood it will be necessary to put the fire out. Some experience is necessary to make charcoal, especially of small material.

TRANSPLANTING WELLINGTONIA GIGANTEA (F. E. D.).—There is some difficulty and danger of removing a tree of so large a size, but we should risk it, digging a trench at 3 feet from the stem, tying the branches up to keep them out of the way so as to facilitate operations, and all round down below the roots, and from this work under the roots towards the stem, and removing the loose soil with a fork, the tree may in all probability be moved with a good ball of earth, in which case there is then no danger; but if the soil be loose, most of it coming away from the roots, it would be well to fill-in the soil again and defer the removal until another year. We find the best time to move *Wellingtonias* is, in spring just when they are commencing growth, or early in autumn.

POSITION OF FURNACE (Munster).—The fire should be taken along the front and back of the house, and the furnace is preferably placed at one end so that the fire be taken across the end to the front, across at the other end to the back, along it to the end where the fire entered, where, of course, should be the chimney. It will not be practicable to heat by fires two houses from one furnace, unless you intend both compartments to be kept at a similar temperature. If you have two furnaces they may be in the centre so as to have both in one stokehole, taking the fires across the end along each side the division to the front of the houses.

DAISIES ON LAWN (Idem).—There is no better plan than to grub-up the Daisies with a knife, a boy removing a great many in a day. Lawn sand is highly spoken of, but we have no experience of it. Can any of our correspondents having given it a trial state what its effects are on Daisies and other lawn weeds?

GERANIUMS NOT FLOWERING (L. B., Bromley).—The glass not being clear is to some extent in fault, but the principal reason of your plants being flowerless is a deficiency of heat. To have Zonal Pelargoniums flowering freely in winter they require a temperature of 50° to 55°, and to have plenty of light.

MUSHROOM BED (A Lady).—Remove the hay as it is wet. The moisture at the surface, if entirely due to the heat arising from the bed, is a good sign, yet we do not like so much moisture given off as to render the covering wet. Have patience, and if the bed dries it is likely you may have plenty of Mushrooms.

FRENCH BEANS NOT GERMINATING (Idem).—Either the seed is bad or there is not sufficient warmth for its germination. The soil requires to be moist, but not wet until the plants appear. The temperature should range between 55° and 65° by artificial means, rising to 75° from sun heat. The seeds should be planted an inch deep.

PEACH WOOD NOT COLOURED (Idem).—The wood being firm and the buds plump there is nothing to fear, only do not allow the soil to become dry or the buds will probably fall. A much lessened supply of water is needed in the winter half of the year, yet the border should be watered so as to keep it thoroughly moist.

NAMES OF CHRYSANTHEMUMS (T. A. N.).—We do not usually name varieties of florists' flowers. No. 1 resembles Christine; 2, Maroon Model; 3, Golden Cedo Nulli.

STOCKS FOR FRUIT TREES (F. C.).—They are grown extensively by nurserymen in the neighbourhood of Woking.

ROSES (F. R. M. R., Kilkenny).—Your letter shall be answered next week.

ARUM DRACUNCULUS (G. W. O.).—This plant and *A. crinitum* are not generally included in select lists of border flowers, but are enumerated in regular lists of herbaceous plants. The plant first named is also known as *Dracunculus vulgaris*.

CELOGYNE (Subscriber).—The plants do not flower because the growths are not well matured. It appears you have flowered one plant freely. If the others have their pseudobulbs similarly ripened they will flower equally well whether the plants are grown in pots or on blocks of wood.

NAMES OF FRUITS (A Thankful Subscriber).—Burré Dial. (E. H. S.). Suffolk Thorn.

NAMES OF PLANTS (Fifteen-years Subscriber).—*Cypripedium insigne*; the yellow Orchid, *Dendrobium chrysanthum*.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

SHEEP FOR THE HOME FARM.

THERE can be no question that the stock of sheep to be kept upon the home farm is a matter requiring great and deliberate consideration, because the county and district must be considered. The climate of England, Wales, Scotland, and Ireland is so various that certain districts of each are found to favour the sheep generally reared in them. The soil and climate go a long way to define and establish different breeds of sheep as belonging to certain counties; hence the Sussex downs, the Hampshire downs, Leicesters, Lincolns, Cotswolds, horned Dorsets, and the little

horned Portland sheep, which resemble the mountain sheep so much prized by Welsh farmers. Then we have also the black-faced horned sheep of the mountains and the chevriots of the lowlands in Scotland. We have thought proper to name these as some of the sheep stock peculiar to certain districts, and likely to influence our choice in selecting sheep stock for the home farm, because we write for the benefit of farms situated in every district of the United Kingdom, which of course includes Ireland. The breed of sheep generally kept upon the rich soils in Ireland are for the most part white-faced, polled, and woolled, whilst those called Kerrys and Wicklows are of a similar type with the horned Welsh mountain sheep, although natives of the mountainous districts of Ireland.

We shall have to consider the requirements of the home farm as in some cases only requiring to keep enough sheep for killing to supply the mansion. In other cases we find a considerable extent both of arable land, park, and pastures upon which sheep must be kept or reared with the view of profit connected with the occupation, and from which the sheep, in considerable though in varying numbers, must be sold at the market price to the butchers; we therefore propose to divide our subject under two headings. First, sheep to be kept and fed for home consumption; and secondly, those to be fattened and sold for profit in the open market.

In the purchase of sheep for consumption we must necessarily take sheep of light weights, in order that small joints of mutton may be obtained which are so much required in the establishments of the wealthy; and it must be remembered that unless a breeding flock is kept the animals must be purchased, particularly as it is desirable to have sheep of two years old and upwards, so that meat of the highest quality and fullest flavour may be secured. This may be done upon a home farm where there is a sufficient extent of land, both arable and pasture, to keep a breeding flock, with the South downs only, as all the other breeds of sheep furnish heavy joints of meat at over two years of age, except the small mountain breeds, which we have before named; but it would not answer to keep breeding flocks of these kinds, unless in some special cases, where we find the home farm situated in some vales in the mountain districts, in which case the small mountain varieties of stock may be reared for fattening, but even then they must be brought into the vales and enclosed lands for twelve or fourteen weeks' good feeding in sheltered situations.

It is necessary to consider that our South downs or Sussex sheep when well fed will furnish capital mutton of moderate-sized joints, still they want the peculiar and venison-like flavour of the horned mountain breeds produced by feeding on the hills upon the heather, wild thyme, and grasses, the produce of the mountain sides.

Upon certain home farms we have for many years brought into the southern counties the black-faced horned sheep from the mountains of Perthshire, but upon their arrival upon the enclosed pastures and park lands they wander about and seem lost, and are with difficulty kept within the bounds assigned to the home farm. It is in such cases that wire fencing is entirely useless to keep mountain sheep within the required bounds, and it is just the same when they are put on to the arable land for a course of root-feeding, as the wattled hurdles are of but little use unless they are set up endways; nor is yarn netting of any service, for being horned sheep they get entangled in the nets and drag down the whole dividing fence of the folding upon root crops. The same argument applies to other mountain breeds, but not with so much force, because the other mountain breeds, and particularly the Portland sheep, are of a more docile temper, and instead of taking the Scotch sheep from Perthshire we are now taking the Portland sheep in preference for feeding upon the home farm. The same may be done with the small Welsh and Irish mountain sheep, because we find numerous home farms attached to the residences of gentlemen distributed over the whole United Kingdom.

We must now consider, whether we take the horned sheep of the mountains or the Sussex downs for fattening, the best mode to be observed in feeding and the mode of management as regards folding, &c., preparatory to being fed upon root crops, and also the time of year when the feeding should commence. In the case of mountain sheep they had best be taken and placed in the park pastures where the grass is highest in our estimation by its stimulating and nutritious qualities, which is about the month of August. There is then plenty of grass, or ought to be, for them to feed upon whilst roaming at large; and finding that they are in good pastures and subject to kind treatment by the shepherd or herdsman they soon become accustomed to the overlooker, who after about a month or so may venture to entice them into a small enclosure or paddock well fenced once a day and offer them food in the troughs, and then they will, if only for sake of curiosity, examine them. Attractive food should then be put in the troughs, than which there is nothing better than carrots in small quantities, the aroma from which is exceedingly grateful. In order that the carrots as soon as the sheep begin to eat them should not scour the animals at this early period, bean meal or barley meal or de-

corticated cotton cake in meal, about half a pound per sheep per day, should be used in conjunction with the roots, the carrots being cut into small pieces by passing twice through Gardener's turnip cutter, and the meal strewn over them will prove the best of all food, and will have the effect of improving the mutton by raising up a good proportion of lean meat as well as fat, for it must be recollected that the small-horned sheep are naturally deficient in flesh. After this mode of feeding in the paddock has been carried out for some little time the animals will become accustomed to be driven better, and will respond to the careful attention of the shepherd. When the pasture feeding is at an end they should be placed upon root-feeding by the shifting fold; but such is the habit of these sheep on their native hills that they seldom entirely forget to value their liberty, we therefore under ordinary circumstances prefer to paddock-feed them until fit to kill, or to keep them in a shifting fold in the field, and to give them rack food, the fold being bare where the root crop is stacked or pitted. There will be no enticing turnip greens outside the fold to induce them to break their bounds. When the animals are settled down into close fold feeding they should of course have the best of hay, which is composed of Dutch and suckling clover or of sweet-scented park hay. This is the only food they will require, besides the above named mixture of meal or cake with the roots, and whether carrots, Swedes, turnips, or mangold are used nothing should remain in the troughs until next day. We do not advise the feeding with linseed cake meal, as it appears to us to induce fatness without producing a due proportion of flesh, besides which we are inclined to the opinion that linseed cake will be more likely to destroy the flavour of the meat to a greater extent than other food, which was originally obtained by feeding upon the heather and herbs of the mountains. After the course of feeding we have recommended these sheep will be found when killed to give mutton of great excellence, of full flavour, and unless fattened beyond the usual period of fifteen or sixteen weeks they will not exceed in weight 14 or 15 lbs. per quarter. Before leaving this part of the subject we must refer to the forest breeds of sheep of the west of England, these being the Exmoor and Dartmoor small breed of small-horned white-faced sheep, located in the high lands of Cornwall and Devonshire, and when taken into feeding as before described they yield very good meat of extremely light weights, being when fat seldom over 12 lbs. per quarter. The method of feeding the south down and other breeds of sheep will be referred to in our next.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour will be rather severe for some time yet, for until the autumn ploughing is done so as to lay the land up high and dry for the winter no relaxation for the animals will be possible, except now and then a wet day, therefore the horses' keep must be liberal and nutritious. Animals for farm work ought to be powerful and capable of drawing from a ton to 24 cwt. each, also able to each of them turn a furrow in ploughing—that is to say, two horses to a double furrow plough, or one horse to draw a single furrow plough; and in ordinary soils such as sand, loam, gravel, and hazel loam or chalk, if the horses are upstanding, and not under 16½ or 17 hands in height, with weight and strength in proportion, and in particular if they are of the Clydesdale stamp and in good condition, they can do this work without being distressed by it if fairly used by the teamsmen. If soils are stronger than those named two horses to a furrow will sometimes be necessary, but then we prefer such work to be done by steam when it can be hired or is kept for use upon the farm. Many farmers will take exception to the point here put forward—that of each horse turning a furrow in ploughing, but objectors in such cases are often acting upon their prejudices or preconceived notions, or otherwise they have in use only small light and under-sized animals, and perhaps out of condition by not receiving rations of corn, fodder, and roots sufficient to keep them in working order, for it must be remembered when horses are full of flesh and condition their actual weight largely increases their power for work. Some chalk carting may now be done, as there are but few farms which do not require chalk or lime in some of the fields, even in those districts where chalk underlies the surface. It is often said on the light chalk hilly soils that it is only to plough a little deeper and to bring up chalk to mix with the surface soil; but this is a mistake, for that which is near the surface is not chalk but merely rubble, it having been robbed of its lime and the other constituents of chalk proper by the action of air and water and the roots of plants during a long series of years, and instead of acting as chalk is required to do, it simply makes these light soils more hollow and unproductive. It is, however, a matter worth consideration, instead of carting chalk when the land rests upon chalk subsoil, especially where the surface soil is heavy and sour, as to the propriety of sinking wells in the fields, as this work is often done by contract, and the chalk when procured by the well-digging process is all hand labour and done by contract at so much per acre, the men lifting the chalk from a considerable depth, and the greater the depth from which it is recovered the softer and better it is for manurial purposes. These wells after furnishing

the chalk required are partially filled and made secure by the tractor, so that in the future the horses can pass over them in security during tillage operations. There are other methods of obtaining chalk in certain districts which must be described on another occasion. The carting and storing of roots or filling-in the field must be continued if not already completed, for although the weather may continue wet it is better than frost for securing roots, the only drawback being the treading of horses and cutting the land into ruts by the cart wheels. The roots if put into store wet will gradually dry if the heap is covered with straw, but not with earth until they are found to be dried in the heaps. At every opportunity wheat sowing will still be continued, only the land at this time must not be ploughed beforehand, but ploughed and sown every day, for when fit to plough the land is fit to receive the seed, especially after turnips fed off by sheep. There is, however, at present prices not much inducement to sow more wheat than can be sown at the usual time, especially upon good barley soils. It would be much better to sow barley in the spring, not only after turnips fed off, but after mangolds pulled, and if the land is clean it should be ploughed in proper-sized ridges according to soil, and remain until the spring, when the first and best season may be obtained, and be likely to produce the best malting barley.

Hand Labour will still be employed in hedging, ditching, banking, wood cutting in the copses, cutting and making the water carriers for irrigating the meadows, also trenching in the meadows and park pastures particularly flat-lying ground, otherwise rushes will make their appearance and injure the quality of the grass and hay, for wherever the rushes and aquatic grasses are found the best and sweetest herbage dies out. Men and women also may now be employed in the meadows and park pastures, taking up docks, brambles, and other wood plants which have arisen from seed or otherwise, the best implement for this work being a small pickaxe with one sharp end $1\frac{1}{2}$ inch wide, the other end pointed. This is called locally when in use a tomahawk, and is extremely useful for weeding at all seasons. The ant hills in the park pastures should be cut down with a sharp spade, and spread and chopped so as to take the frost and kill the ants, and where there are many to dig out and spread the chain harrow may be employed with advantage when the weather is dry enough. In some light sandy or gravelly soils heather and gorse plants will sometimes be found; these also must be lifted and carried away, this being the time of year when they may be rooted out easily, the ground being soft, and some of these may be pulled by hand and a stout harvest glove whilst the plants are young. The yard man must now give attention to the breeding sows and young pigs; this is also the time to put up some pigs to fatten for home use, both for pork and bacon. The best breed of pigs we shall describe before long.

THE POULTRY CLUB'S RULES FOR SHOWS.

We published in our issue of October 10th some rules issued by the Poultry Club for obligatory insertion in the schedules of all shows held under its patronage. They have the merit of brevity and conciseness, and we think that the Club has done wisely to publish them in this form; at the same time we hope that the larger and more general code of rules for the good management of shows before published has not been entirely rescinded, but will, as promised, be speedily incorporated in the rules of the Club, for their object is excellent, and, to judge from a bundle of schedules now before us, their influence has been considerable. We will briefly comment upon these six rules in order.

"1, Any exhibitor who has been disqualified by the Committee of the Poultry Club for fraudulent practices is ineligible to compete at this show." At first sight this looks somewhat over-stringent, but when we analyse the other rules of the Club we find that this disqualification is no arbitrary proceeding. When the judge of a show held under Poultry Club rules has disqualified a pen the matter will be laid before the Committee of the Club. Of course it is not their province to revise the decision of the judge, which is final in the particular case, but there may be extenuating or almost absolving circumstances—*e.g.*, the exhibitor may be a person unacquainted with the secrets of poultrymen, and may have lately bought the bird or birds from some too-talented vendor. If in such a case the exhibitor is willing and desirous to trace the guilt home to the guilty party it is obvious that no blame beyond that of carelessness can attach to him, and the Committee of the Club would prevent any further consequence following the disqualification. Or again, an exhibitor may employ a poultryman who is solely responsible for the fraud. Of course care must be taken that dishonest fanciers do not screen themselves behind their servants; but we think it but fair that in such a case, should it be clearly proved that the blame attaches entirely to the servant, the master should have one warning, and, should he continue to employ the man, then be considered responsible for any of his tricks.

"2, No person is allowed to exhibit borrowed birds." This is a very plain rule, and we hope pains will be taken to carry it out. Borrowing of birds for show is for many reasons a most objectionable practice, and one which we believe has often been resorted to

by really honest exhibitors simply because it has not been clearly forbidden. Point cups have encouraged it much. We have a lively recollection of having once competed for a point cup and lost it by one point, simply from an exhibitor having won first prize in several classes with birds well known to be borrowed.

"3, Exhibitors and their servants will not be allowed to pen or unpen their birds." This rule we desire to see fairly and firmly carried out. It is not that we distrust the large body of exhibitors, or would willingly debar them from the satisfaction of seeing their birds safely into their pens, but experience has shown us that many who cannot be trusted often get beforehand into exhibition rooms and have often done much harm. It is fairer, too, for all that no one should have the opportunity of giving a last smoothing touch to birds ruffled in their baskets, as all cannot possibly give it. Some distinction may plausibly be drawn between the cases of penning and unpenning. Committees are glad to get a lot of pens belonging to one exhibitor quickly taken off together, and so generally encourage this personal removal; but it is very easy for exhibitors to hand-in a list of their numbers and for a committeeman to collect them and hand them over to their owner. The rule used to be well and successfully carried out at the later Bristol shows. The reason of this we happen to know. We were present at the close of one of the shows some seven or eight years ago. A lot of people came in to take away their exhibits late at night. Suddenly there was a scuffle after a Spanish hen which had escaped. She was caught and the supposed owner promptly carried her off. It was soon, however, discovered that the whole affair was a trick, and that one of the first-prize hens, considered worth £20, had been stolen by some unknown individual who had entered a worthless pair simply to gain the *entrée* to the building. As far as we can recollect the police were never able fully to track out the offender.

"4, No bird may be removed from the show before the close of the same, save on account of illness and with the Secretary's consent." This might be thought quite a superfluous rule, but it is by no means so. It is not an uncommon thing, of course with the connivance of the authorities, for a bird to be taken out of its pen after the first day of a show, or even soon after the judge has been round, and sent to win at another show, an inferior specimen being substituted for it. The public are hereby taken in, having paid to see the prize birds and being shown others in their stead. We were astonished one year at Birmingham (of all places!) to discover that something of the kind had been done. We wished on the last day of the show to examine some famed Dark Brahma pullets which had won. On looking them over we observed, "after all one is not so extraordinarily good." "Oh!" replied a person in the secret, "the real one is winning to-day at—Show; she was taken out last night, and this one sent in her place." On the other hand we remember one year at Oxford a Dorking champion really looked mopy, but not seriously so, yet the Committee steadfastly refused to let him go home, for the good reason that they must not break faith with the public.

"5, It will be open to anyone to lodge a protest for fraudulent practices against an exhibitor on paying £1 deposit, and such further sum as shall be necessary to defray the expenses, the deposit to be forfeited should the protest be considered frivolous by the Committee. Should the protest be sustained the deposit will be returned and the expenses paid by the Poultry Club." This seems a good and carefully drawn rule. It is often expensive to bring a judge back to a show which he has left; this difficulty is obviated by the provision concerning expenses. There is also some temptation for a judge to declare a protest frivolous, the decision on the point is therefore left with the Committee. While the deposit should be enough to deter all foolish protests, the liberal offer of the Club to pay all expenses in the case of those sustained should be encouragement to exhibitors not to shrink from their duty to point out malpractices where they are evident.

"6, An exhibitor who shall be disqualified for fraudulent practices shall forfeit all or any prizes or cups that may have been awarded to him or her at this show in addition to entry fees." We have often contended for the adoption of this rule, and so need say little more about it. It was disgraceful that, as heretofore, at the greatest shows a person might carry off a ten-guinea cup in one class, and in another be disqualified for pulling out hock feathers or carving a comb. It is a further question whether some provision could not be made for the payment of prizes to an exhibitor who has one pen disqualified owing solely to the fault of another person. Such cases, however, are rare, and we incline to think that he should pay the penalty of carelessness.—C.

LANGSHANS.

THOUGH not an exhibitor at shows I have been an observer and a breeder of poultry for many years, and without hesitation I say that the Langshan is the most meritorious breed that has ever been introduced into this country. At first sight, when the chickens leave the nest they are exceedingly like Cochins China chickens, destined to be black and white, but all so exactly like each other as to show at once that they are in all probability a

distinct breed. One can scarcely imagine that such chickens can ever become black; yet as the feathers appear, except in the wings, the first feathers (in which are mostly white—the white down) disappear, and there can be no doubt any longer as to what the colour will be, for black takes the place of white. As the chick grows its bony frame is observed to be much lighter in build, like a thorough-bred horse in comparison with a cart horse. The bird is more active and able to make more use of its wings than a Cochins or Brahma; its breastbone is much longer, the thigh much smaller in proportion to the breast, the legs less feathered and without a trace of yellow, being black, pink, and white, with the nails on the black claws pearly white. The skin is delicately white, and the flesh upon the breast abundant in comparison with either the Cochins or the Brahma. Of two chickens hatched in the same nest and reared together, the one a fine Dark Brahma cockerel, the other a Langshan, at a little more than three months old as nearly as possible of the same size in appearance, I carefully measured the length of the breastbones. The Brahmas measured $3\frac{1}{2}$ inches, the Langshan's $4\frac{1}{2}$ inches. My Langshans are pure-bred birds, obtained from Mr. Crood of the Manor House, Durrington, near Worthing. Their purity of breed I have ascertained to my own satisfaction thus: I obtained some very pure Duckwing Game birds, and have bred a cross between these two pure breeds; now the cross-bred birds are all so exactly like each other as to exclude the most remote probability of any taint of blood in the parentage on either side. I have done more: I have proved that a Light Brahma hen, supposed to have been a pure-bred fowl, is nothing of the kind, her chickens being of all colours when crossed with the pure Langshan; a White Dorking hen also, which I knew was not quite true bred, throwing chickens of all colours in the same way. I think the above facts satisfactorily prove that my Langshans and Game birds are pure breeds, and that the slightest cross in either parent will be unmistakably shown by varieties in colour, &c., in the produce of such birds, every breed as it were peeping out here and there. I have no doubt that several of the birds exhibited last year at Birmingham as Langshans had a considerable amount of Black Cochins blood in them; but in time this mixture will be recognised and all contamination will be got rid of.

I have a rose-combed variety of Langshan, and I understand in the pure bred tufted birds appear occasionally. I do not think the best Langshans have yet been brought from their native country. Everybody knows how perseveringly the Cochins and the Brahma will sit, and how frequently they want to sit. The Langshan is very easily prevented, and if allowed to sit is very apt to desert her nest before the time of hatching has arrived. Langshans are extraordinary layers, their eggs being not large for the size of the bird but very rich. The colour of the shell varies from a dark brown to almost white, and is sometimes spotted like a Turkey's egg. It is a richer and better egg than the Cochins' or the Dark Brahma's, the Light Brahma's egg coming nearest to it in quality.—JOHN GABB, *Surgeon, Bewdley.*

ROOT SHOWS.

THE first condition for securing good crops is to obtain good seed—pure stocks of approved varieties. Without this, cultivation fails in the object desired; with it success, so far as the elements permit, is certain. Where good seed and good culture are combined remarkable results are achieved, of which a trio of root shows recently held afforded sufficient evidence. Alike on account of the magnitude of the exhibitions, the excellence of the produce, and the enterprise of the promoters of these great agricultural gatherings, the shows in question merit notice. First in order of date was the exhibition of

MESSRS. WEBB & SONS.

During previous years great displays of roots which have been grown from seed supplied by Messrs. Webb & Sons have been arranged in their capacious warehouses at Wordsley near Stourbridge. This year the Show was held in Curzon Hall, Birmingham, where it opened on the 20th inst., and was the most extensive of its kind that has ever been seen in the midland counties. The value of the prizes offered was £300, making a total of £500 offered by Messrs. Webb during the year for superior cultivation. The number of entries for the Show was 1612 (comprising 25,000 roots) against 1308 in 1877. Amongst the exhibitors were Her Majesty the Queen, His Royal Highness the Prince of Wales, the Duke of Portland, the Duke of Sutherland, Earl Beauchamp, the Earl of Dartmouth, the Earl of Northbrook, the Earl of Powis, Earl Redesdale, the Earl of Stamford, the Earl of Warwick, the Earl of Wemyss, Lord Bateman, Lord Hampton, Lord Moreton, Lord Northwick, Lord Willoughby de Broke, and many other large landed proprietors.

Webbs' Imperial Swede, of which there were 511 entries, formed a prominent feature of the Exhibition. Mr. Joseph Beach won the cup with produce of remarkable quality. The first prize for weight of roots was taken by Mr. R. Lloyd, Kidderminster. The twelve heaviest Swedes in the hall weighed 268 lbs. Of Webbs' Improved Colonel North Mangold there were 214 entries. The

first prize for the "best" was won by Mr. T. H. Farrer. The heaviest single Mangold of this variety in the hall weighed 39 lbs. Webbs' Mammoth Long Red Mangolds were extremely fine. Mr. F. Lythall was awarded the first prize for the best roots. The prize for the heaviest was won by Mr. T. Moxon, Easenhall, with a collection of twelve, weighing 479 lbs. A single root of this variety, shown by itself, weighed 62½ lbs. Sir R. F. Sutton won the chief prize for Webbs' New Kinver Yellow Globe Mangold. The heaviest collection of Globe Mangolds weighed 363½ lbs., and the heaviest single specimen 39 lbs. Webbs' Yellow-fleshed Tankard Mangold was well represented; Mrs. Cubberley, Alcester, securing the first prize. For Webbs' Intermediate Mangolds there were forty-nine competitors. Turnips, Kohl Rabi, and Cabbages were all excellent.

Superior vegetables were exhibited, and five hundred varieties of Potatoes grown by the firm on their trial grounds at Kinver attracted much attention.

The cereal classes contained excellent samples of Webbs' Challenge White Wheat, Kinver Chevalier Barley, Black Tartarian Oat, and Challenge White Oat. 4600 visitors attended the Show on the first day, and 7321 on the second.

The Exhibition on the whole was an excellent one, and highly creditable to Messrs. Webb and their numerous customers.

MESSRS. SUTTONS & SONS.

Only those who have visited the Royal Berkshire Root Show can form any just conception of its magnitude and of the vast concourse of visitors which crowd around the collections. The prizes offered by the firm during the year amount to £500, and are competed for by cultivators in almost every county in the kingdom. Amongst the exhibitors at the Show in question were Her Majesty the Queen, H.R.H. the Prince of Wales, the Duke of Northumberland, the Duke of Portland, the Marquis of Ailesbury, the Marquis of Donegal, the Earl of Craven, the Earl of Northbrook, Earl Bathurst, the Earl of Redesdale, the Earl of Warwick, Lord Calthorpe, Lord Camoys, Lord Chesham, Lord Eversley, Lord F. Kerr, Lord Moreton, Mr. W. H. Smith, M.P. (First Lord of the Admiralty), the Countess of Yarborough, and many other principal landowners and tenant farmers.

The number of entries was 1574. Tons upon tons of the most splendid roots of Mangold Wurtzels, Swede Turnips, Parsnips, and Carrots, &c., were gathered together in the magnificent premises of Messrs. Sutton in a room 180 feet long by 60 wide, and in four other rooms adjoining, probably the largest in the world used for such purposes. "My farming," observed a visitor speaking of the Show, "is of a limited character, but I have some idea that a produce of 110 tons an acre is a pretty considerable amount for even Mammoth Mangolds; that for six Long Red roots to weigh 233 lbs. is no little matter, and that it cannot be a baby root that is 3 feet 3 inches long, 3 feet in girth, and weighing 47 lbs." Yet such were a few of the recorded weights, and even large farmers were astonished at the excellence of the display.

In Class 1, for the "grand prize," a gold cup value £20, for thirty-six roots of Mangold Wurtzels in three of Messrs. Suttons' varieties, there were twenty entries. The Judges, after long and close examination, awarded the prize to Sir Paul Hunter, Bart., Mortimer Hill. The twelve roots of Suttons' Mammoth Long Red weighed 406 lbs., a similar number of Golden Tankard weighing 315 lbs., of Sutton's Berkshire Prize 377 lbs.—total, 1098. This was a splendid collection, many of the roots being handsome as well as large, but others were undoubtedly somewhat coarse. Much more attractive in appearance were the roots exhibited by R. Burn Blyth, Esq., Woolhampton, who was awarded the second prize of £10. The aggregate weight of the thirty-six roots was 770 lbs., but for smoothness and shape they were far in advance of all others, every root being a model of good culture. In this fine class size triumphed over quality, but in the next class for six Suttons' Mammoth Long Red Mangolds—a remarkable class of nearly a thousand roots—quality was worthily recognised in the first-prize collection of Sir F. Smith, Bart., Acton Burnell, which weighed 205 lbs., against the second-prize six of Sir Paul Hunter, weighing 233 lbs. The class for six roots of Suttons' Berkshire Prize Yellow Globe Mangold was a very imposing one, the roots combining size with quality in a remarkable manner. The first-prize collection of Mr. Richard Webb, Beenham, weighed 181 lbs. Similarly fine was the class of six Suttons' Yellow Intermediate Mangold, where Sir Paul Hunter was again in the first position with roots weighing 161 lbs. The same successful exhibitor was first in the class for six roots of Suttons' Golden Tankard Mangold with a collection weighing 181 lbs.; some of the roots were a foot out of the ground, and of the true tankard shape. A fine class.

Swedes were remarkable for their numbers and general high quality. For twelve roots of the famed Suttons' Champion, J. F. Burrell, Esq., Frimley, won the first position with short-necked smooth handsome roots of great solidity. Many other collections were nearly equally good, no less than thirteen exhibitors receiving honours in this class. The same number of competitors was honoured in the class for twelve roots of Suttons' Imperial Green Globe Turnips, J. S. Calvert, Esq., Witney, heading the list. The class was an excellent one throughout, the majority of the roots

being models of their kind. Similar remarks apply to the White Globe Turnips, in which class Mr. Wills, Lambourne, secured the chief prize. Other varieties of Turnips were very fine, notably Suttons' Green-top Yellow Hybrid, in which class Sir Curtis Lampson, Bart., Rowfant, was awarded the first prize. Kohl Rabi was excellently represented, and Drumhead Cabbages attracted much attention. The three heaviest weighed 161 lbs., the heaviest single specimen weighing 56 lbs. Mr. S. Robinson, Melbourne, was the premier exhibitor. White Carrots were much better than the Reds, and Parsnips were numerous and superior. Classes for roots grown with sewage were well filled, the Reading Sanitary Authority being the most successful exhibitor with produce of very high quality. The Show throughout was a splendid one, and the arrangements were complete in every detail.

MESSRS. CARTER & CO.

This annual Show of roots which have grown from seed supplied by Messrs. Carter & Co. was held in the Agricultural Hall, London, on November 23rd. The prizes offered were of similar value to those provided by the firms above noticed. The Show was undoubtedly one of the best ever held by the firm, not only on account of the immense number of roots exhibited, but also in consequence of the very superior quality of some and the general excellence noticeable throughout the many well-filled classes of the Show. The root crops are a very important element in the food production of this country, and much credit is due to the great seed firms for the encouragement given to the production of superior and heavy crops.

This year Messrs. Carter exhibited a large consignment of extraordinary roots grown from their seed in Canada. This transatlantic produce attracted much attention. The roots consisted of the following varieties—Carter's Mammoth Long Red Mangold, the heaviest weighing 63 lbs., and eight roots 480 lbs.; Carter's Warden Yellow Globe Mangold, the heaviest 60 lbs.; and Carter's new Yellow-fleshed Tankard Mangold, the heaviest weighing 32½ lbs. From the Royal farms of Her Majesty the Queen and H.R.H. the Prince of Wales came a group of the different varieties of Carter's Mangold. These were not entered for competition, but were of excellent quality, not particularly large, but very clean and shapable. The following noblemen interested in agriculture were represented in several of the classes—the Duke of Northumberland, Earl of Harrington, Lord Redesdale, Lord Clinton, Earl of Warwick, Lord Sondes, Sir Wm. Farquhar, Sir Curtis Lampson, Sir Charles Russell, Admiral Sir G. N. B. Myddleton, Sir Richard F. Sutton, Major Allfrey, &c., and there were contributions also from large farmers, schools, asylums, and sewage works.

In the class for twelve roots of Carter's Imperial Hardy Prize-winner Swede there were seventy-three entries. E. Pilcher, Esq., was first, Messrs. T. C. and A. H. Borthwick second, and W. Beckett, Esq., third. This class was remarkable for the evenness of the roots, hardy appearance, and truthfulness to name. For the heaviest root of this variety T. Moxon, Esq., was first, and for the handsomest the Middlesex County Asylum (Mr. F. Alderton, steward) gained a similar award. For eight roots of Carter's Warden Yellow Globe Mangold there were sixty-seven entries. T. Southern, Esq., was in the first position. This was another grand class, the variety a very handsome one. For the heaviest root J. Clarke, Esq., was first; and for the handsomest, T. H. Farrer, Esq. For eight roots of Carter's Mammoth Long Red Mangold there were forty-seven entries, J. Clarke, Esq., winning the first prize. The specimens generally were not only large but of excellent shape. For eight roots of Carter's Intermediate Mangold there were thirty-nine entries. Mrs. Morten (Mr. J. Cave, steward) was placed first. A really fine class. For eight roots of Carter's Yellow Tankard-shaped Mangold there were thirty entries. J. Clarke, Esq., was first. A clean good class of an increasingly popular variety.

For twelve roots of White Globe Turnips there were eleven entries. Mrs. Morton was first with superior produce. The competition in the Turnip classes was weaker than usual, the season having proved unfavourable to their growth. The prizewinning roots in all the classes were remarkably handsome, notably in that for twelve roots of Red Lincoln or Paragon, and for twelve roots of Carter's Imperial Green Globe. For eight roots of Carter's Imperial Green Kohl Rabi there were twenty-three entries, the Birmingham Corporation Sewage Farms (Mr. J. Anscombe, steward) securing the first prize. This was by far the best lot of Kohl Rabi ever seen at Messrs. Carter's Show.

Silver cups were gained by Lord Warwick for six roots of Carter's Warden Prize Mangold, and the Eton Local Board (Mr. C. Tough, steward) for six roots of Carter's Imperial Mammoth Mangold. A silver cup offered by Messrs. J. Gibbs & Co. for the best collection of roots grown with their manures was taken by the South Metropolitan District Schools. Another cup offered by Messrs. Ohlendorff & Co. for the best twelve roots of two varieties of Mangold grown with their guano or phosphatic manures was awarded to Messrs. E. & R. Emery. Some idea of the extent of the Show can be formed when it is stated that the whole of the gallery surrounding the hall was occupied by the various ex-

hibits. Messrs. Carter are to be congratulated upon the extent and quality of the produce, and also upon the able manner in which the Show was managed.

VARIETIES.

We were glad at the late Crystal Palace Poultry Show to see traces of benefit from the International Exhibition in Paris. In the Any other colour Polish classes Mr. Beldon's magnificent Buff hen which took second prize, and Mr. Reville's pure White cock and hen which took third prizes were, we feel certain, birds which won at the Paris Show. These two breeds were almost or quite extinct in this country, and we are very glad to see some chance of their being resuscitated through these new importations.

— THE Lancaster Poultry Show which was to have taken place last week, was indefinitely postponed in consequence of the very small number of entries. The course taken by the Committee—viz., that of returning all entry fees, was a straightforward one, and far preferable to the too common practice of touting for late entries. The cause of this failure of entries was doubtless due to the earlier date chosen this year for the Show. The prize list was liberal, and eminent Judges were secured, so we can see no other reason for the failure of what has hitherto been a large and successful meeting. We do not believe that any show on a large scale, save so old-established a one as Oakham, will prosper between the Crystal Palace and Birmingham.

— THE Bexley Heath Show is among the number of those for which application has been made for late entries in special classes. We should like to see this practice stopped, especially as it appears from the discussion of the subject at the late meeting of the Poultry Club, and in the columns of a contemporary, "that the admission of entries after the day on which they are stated to close is positively illegal." There seems little doubt that an unsuccessful exhibitor would have a good case against a committee who had accepted post entries.

— We hear that the Committee of the Poultry Club has been invited to consider the question of railways, who declare that they will not be "common carriers of poultry," and who require consigners of poultry to sign a paper to the effect that they consign them at their own risk. Strong evidence is forthcoming that the Companies break the law by this requisition, and are very well aware of the fact, but continue to rely on public ignorance. We hope that the Club, if after due notice these Companies do not abandon such regulations, will try a test case and publish the result to all the poultry-fancying public.

— We have a large batch of schedules of forthcoming shows before us. First in magnitude and importance is that of Shrewsbury, fixed for January 2nd and 3rd. There are forty-four classes for live poultry, which, save in the case of Game, are shown in pairs of cock and hen. The prize list is very liberal, there being three prizes in each class, the first of £3 for the more popular varieties, and £2 for the rest, and this with an entry fee of only 5s. There are three classes for Dorkings, four for Cochins, seven for Game, five for Hamburgs; Malays, Leghorns, Andalusions, Sultans, Langshans, and Silkies all have classes. There are also four local classes for dead poultry. Pigeons have twenty-five classes, with the unusually low entrance fee of 3s. The subdivision of varieties is good, and we are specially glad to see a class for "Short-billed Frilled varieties," which will doubtless be a well-filled and very attractive one. The Judges are for poultry Messrs. Hewitt and Teebay, and for Pigeons Mr. Esquilant. The Show adopts the Poultry Club rules, which are printed in the schedule. The Swindon Show will be held on December 31st and January 1st. There are twenty-eight open classes for poultry shown in pairs, and eighteen for Pigeons partly shown singly and partly in pairs. There are also many local classes. The programme includes an exhibition of Cage birds, Rabbits, and Cats. The Judges are to be Mr. John Martin, Mr. P. H. Jones, and Mr. H. E. Gilbert. The Poole Show is fixed for January 1st and 2nd. There are twenty-five classes for poultry, twenty-one for Pigeons, and eight for Cage birds. It will be held under the rules of the Poultry Club. The Judges are Rev. Grenville Hodson, Mr. W. B. Tegetmeier, and Mr. Billett. A Show will be held at Jersey on January 8th and 9th. The classification is good, and birds are shown singly. There are forty-four classes for poultry, nine for Pigeons, and ten for Cage birds. Many cups and special prizes are offered. The Judge is Mr. O. E. Cresswell. In addition of these poultry-show schedules we have those of the Oxford and Surrey Columbarian Societies. The former will hold its Show at Oxford on December 11th, and the latter at Guildford on December 10th and 11th.

— THE *Prairie Farmer* alludes as follows to American exports, which now exert such a great influence on the food supply of this country. In 1858 the population of Great Britain, exclusive of the army, navy, and seamen abroad, was 28,389,770. In 1877 it was 33,444,419. In 1858 the total value of imports of live cattle, sheep, and swine was £1,390,068; of dead meats and provisions, £4,343,592. In 1877 it rose to £6,012,564 for live stock,

and £30,144,013 for dead meats and provisions. Thus the imports of Great Britain of animals alive and dead has increased from a total of £5,733,660 per year to £36,156,577 per year. The import of wheat, other grain and flour, has steadily increased from £20,164,811 in 1858 to £63,536,322 in 1877, making a total import for 1877 of live and dead animals, and animal products, grain and flour, of £99,692,899. Last year we had over a hundred million bushels of exportable grain. It is estimated that this season we shall have 180 million bushels for export.

WINTERING BEES ECONOMICALLY.

THERE is no greater blunder in practical bee-keeping than the retention at the end of the season of an array of weak and sparsely peopled hives, which, like Pharaoh's lean kine, eat up the fat, and very probably in the long run giving way after consuming a considerable amount of both food and trouble, which is altogether wasted and as bad as thrown away; whereas, by uniting two or three such hives together, say one on either side, to a central, a first-rate dependable stock is established for the succeeding season, and in that excellent translation by the late Miss Graham of Duntrune of Jonas De Gelieu's interesting work "The Bee Preserver" we find that author takes credit for the discovery of the fact that such conjoined stocks can be wintered as economically as any one single kept separate. The soundness of this position he incontestably proves by lists of experiments repeated over and over again, and yet confesses his inability to account for, to him, the surprising and unexpected result. His talented translator gives copious proofs in the appendix of her experience with her own and her gardener's hives, and the diminished weights from September to March of the years 1828 and 1829 confirmatory of the hypothesis, only one of which I will adduce. She says, page 133, "The gardener's hive No. 2 received two swarms in addition to its own, and this allied army took possession just as peaceably as the others, and actually consumed less honey during the winter than No. 1, which was only doubled."

Every tyro of our day has verified this discovery for himself, and ought to be able to satisfactorily account for it. The natural heat emanating from the combined body keeps up the temperature of the hive to the required point, and the inmates are thus enabled to enjoy their comparatively undisturbed dormancy with the minimum of exertion and consequent consumption of store; whereas in the sparsely peopled hive the quickened respiratory action and increased muscular exertion to raise the temperature demands food to supply the waste of the system, clearly resulting in the fewer months of the separate and more active consuming as much food as the conjoined.

Your correspondent Mr. Pettigrew having previously challenged the accuracy of the observations of the illustrious Huber, which notwithstanding will continue to elicit the admiration of the apiarians of all time, is it to be wondered at if the discovery of the gentle Swiss pastor should be scoffed at, and the credulity of the advanced bee-keepers be denounced from "the paddle box" as follows, page 269?—"What a mistake the Swiss clergyman made in asserting that a large swarm of bees does not eat more food in winter than a small one! and what a strange thing that so many advanced English bee-keepers believed his statements!"

It may prove interesting here to note that the above highly accomplished lady, who moved in the best Edinburgh society of half a century ago, and whose ready wit drew forth the encomiums of such celebrities as Scott and Jeffrey, died towards the end of last year, having attained the great age of over ninety-five years. She was the last representative of the old family of Graham of Claverhouse, one of her ancestors being Viscount Dundee, better known in Scottish history as "The Bloody Claverhouse." She retained all her faculties to the last, and with them the warmest interest in her old favourites. A letter she addressed a few months before her death to the present writer on our common hobby was alike remarkable for the chasteness of its style as well as the beauty of its calligraphy.—A RENFREWSHIRE BEE-KEEPER.

BEES' UNPRODUCTIVE EGGS.

A RECENT correspondent of this Journal, in his observations on the subject of unproductive eggs in a particular hive to which I drew attention some weeks ago, has missed the singularity of the particular circumstances as detailed by me. Everybody knows that bees not only remove eggs when they do not want them but even devour them freely, as for instance in the case of a sudden glut of honey coming on as well as in the cases described by him. What I remarked upon as singular was that the bees in this case, at the very time they were being liberally and continuously fed for the express purpose of encouraging an increase of population, yet not so bountifully as to amount to a glut of food supplied, allowed the queen to lay again and again a quantity of eggs which the bees did not suffer to reach maturity, but appear to have devoured for some inscrutable reason, and quite out of their usual custom when being so fed. If they did devour or remove them, which is your respected correspondent's only solution of the

matter, I think it a very curious circumstance. I ventured upon suggesting two other causes as possible; namely, either a temporary weakness—call it impotence or barrenness on the part of the queen or a weariness on the part of the whole hive—at the usual rest period of the year, after the labours of an exhausting summer. It does not seem to me as if either of these suggestions is absurd or beyond the reach of probability as an explanation.—B. & W.

THE NATURAL AND THE ARTIFICIAL.

ABOUT five months ago some notes from my pen appeared in the columns of the Journal under the above heading. The price of artificial comb foundations was referred to, and this question was asked, Are they worth their price? Mr. Arthur Todd answered this question from the distant land of Algeria. I was pleased with the tone and earnestness of Mr. Todd's letter. He energetically endeavoured to prove that they are well worth their price and most useful to bee-keepers. His figures I could not understand, and certainly they did not touch the comparisons of my letter between the cost of artificial foundations and perfect combs made by bees from sugar syrup. I may here say that I never disapproved of the use of artificial comb foundations. From the first notice of them I have been of opinion that they would be of great service in apiculture if bees readily adopted them. In the first number of the Journal for 1873 my letter on "Bee-keeping, Past, Present, and Future" appeared; and in that letter I predicted that with artificial comb foundations in use supering in the future would assume new proportions and eclipse supering in the past. I am of the same opinion still. The instrument that makes the foundations and the foundations made by the instrument are wonderfully perfect. Mr. Todd says, "I quite agree with the best American authorities in that for the brood chamber the artificial foundation is a magnificent success; but that for supers, unless an excessively thin foundation be used, it is best not to tack on the word artificial to super honey, and so leave it open to the charge of being adulterated." I am disappointed to learn that Mr. Todd does not approve of the foundations being used in supering or for super honey, for, as I have already said, I have been in great hopes that the foundations would be most useful in supering. Notwithstanding what he says in disapproval of their use I still cherish the idea that they will be very serviceable and extensively used in supering. On writing on this subject before I stated that wax as well as flax could be bleached, and that the foundations for supering should be made for white or bleached wax. Some of the foundations that come down from London at present are of a golden colour and will not do for supering. It is to be hoped that attention will be given to the manufacture of foundations white enough and thin enough for honeycomb. As far as Mr. Todd's experience goes the foundations answer well for hives and broodcombs, and that bees take to them readily, and this certainly is no small gain and advantage in bee-keeping.

As to price, it appears to me that while wax sells at 2s. per lb. the foundations must cost considerably more if made in England. In America both honey and wax are cheaper, and foundations may be sold at a lower price there than they can be in England.

In comparing the cost of artificial foundations with that of natural combs made from artificial feeding, in my first letter I found a margin of gain on the side of the natural. From 20 lbs. of sugar we obtain 40 lbs. of syrup, and from this a swarm of bees in September or October can fill a bar frame or straw hive full of beautiful white combs and store up about 20 lbs. of syrup honey; all this for 5s. If the bees be removed there remains a hive full of pure white virgin combs half filled with syrup. Of course the syrup should be removed from the combs before they are used for supering, and the only way of getting it out is to let the bees of other hives or another swarm take it. Thus perfect and beautiful natural combs may be had for supering, incomparably better and probably cheaper than artificial foundations. The trouble of filling supers thus in autumn with perfect combs would be great, and therefore the artificial foundations are welcomed amongst us; and I earnestly hope that all that has been said in their favour may be fully realised in the future experience of British bee-keepers.—A. PETTIGREW.

MELTING COMBS DOWN INTO WAX.

THE first time I tried the boiling plan I found it so much trouble and took so much time that I made up my mind if I could not find a better plan I should melt no more except a little for my own use. I now take a large dish of any kind that will stand the heat of an oven, such as a common pie dish, or a roasting tin will do—anything that will hold water; then put another smaller dish inside that for the wax to melt into; then fill the bottom dish with water, and cover the inside dish with a piece of fine copper gauze turned up a little all round to prevent the combs from falling off. On this gauze put the combs, squeezing them together so that it will hold more; the wax will melt through and leave the refuse on the top. Turn it over a little now and then, so that the wax may find its way through the refuse, and press it gently but not too much, else the dirt will go through as well as the wax.

When there is a refuse on the top take it off, throw it away, and replenish again until all is done.

There is not much wax wasted by this method. The water in the bottom dish is to keep the wax from burning in the inside one. The mistress of the house can do it while she is attending to her ordinary house work, for all that is needed is to keep plenty of combs on the gauze and turn it over now and then. It is also much safer than boiling, for there is no fear of its getting on fire. It is also more expeditious, at least for anyone who has not special advantages. With large dishes and a good hot oven many combs may soon be melted. Cleaning the utensils used for boiling is tedious, but by this method only one dish needs to be touched with wax. When the dish is full of wax empty it into small moulds to suit the requirements of the owner.—P. RAINFORD.

THE STEWARTON HIVE AND OTHER MATTERS.

I AM described on page 359 as "a fault-finder with almost everybody and everything." Would your correspondent Mr. Pettigrew be pleased to point out where I have used personal allusions of a character not suitable for the intelligence of the present day, or employed the slightest discourteous expression towards Mr. George Fox or any contributor to the *Journal of Horticulture*? Where did I say the bar-frame hive was wrong? Who ever dreamed but himself that two 6-inch boxes formed a Stewarton set? I never used, much less had been successful in filling supers on any such. These are all inaccurate assertions.

I am also accused of finding fault with Mr. Pettigrew's last year's article on the Stewarton hive, wherein he quotes from Mr. Hunter's book. So far from this being the case I am innocent of writing a line in this periodical for six months after that article appeared, and was forced to break that silence on finding our captain so far out of his reckoning as to introduce comb foundation as a novelty of American invention in a journal which had recorded its German discovery fifteen years before! and so clearly defined its advantages that its fabrication became an indispensable in every advanced Scottish apiary since.

Your correspondent has asked me to demonstrate how "the deeper mysteries of apian science are to the skepist a sealed book, while to the bar-framer they are laid naked and bare for inspection." The paragraph is from a communication of "A LANARKSHIRE BEE-KEEPER" on "Fertile Workers" page 120. It explains itself. The hive is the apian book, the skepist reads his upside down—an unscholarly position—the bees resent the indignity, fustian rag smoke is blown up amongst them, and the living type to be read drop from their position amongst its leaves, or combs. These are sealed by being skewered fast with five or six cross sticks through them; they cannot be moved or turned. They are peered into like a sealed book, and the peerer turns on his heel and imagines a thing or two. On the other hand the framist can by gently withdrawing a slide on either side read one leaf without disturbing the rest, or page by page as he inclines; or for more careful study transfers them all to his observatory, which, like a glazed newspaper stand, can be perused on both sides by different students at one and the same time, and with what different conclusions from the skepist! Take fertile workers as an example. These were first noticed by Riem, the rudiments of the ovary in all workers established by the clever anatomist Miss Jurine, their experiments confirmed by Huber and all apianians down to our own Woodbury, parallel instances occurring in the humble bee, the wasp, and the ant, in each case, like the hive bee, an exclusively male progeny resulting. I have possessed on several occasions, even in one season, queenless nucleus with fertile workers depositing one to four drone eggs in worker cells. "A LANARKSHIRE BEE-KEEPER" has had such frequently, and, to dispose for ever of all cavillers, offered this last summer the fertile worker for public inspection, and that able entomologist Mr. R. J. Bennett has quite recently given his testimony. But what does Mr. Pettigrew write?—"I fearlessly affirm that there never was and never will be a fertile working bee." I respectfully submit, Is this the language of "a lover of truth more than his own opinions?"

Long before Mr. Pettigrew came amongst us I pointed out the necessity on breaking-up hives of keeping separate and distinct the sealed from the unsealed honey; his pet twice swallowing and disgorging theory I much fear is without any foundation in fact. According to it we storifiers would see the honey deposited in the body during the day and at night transferred to the supers; on the contrary the honey gathers stream right up to the supers with their loads. In the observatory the individual bee can be traced from the entrance direct to the upper honey cell, and the extraction of the watery and aerial element before sealing, which enables the sealed honey more readily to consolidate and keep.

All animated nature must rest; even the busy bee, as I have already put it, enjoys its well-earned repose. Your correspondent may not be aware bees work in relays. We readers of the open book—the observatory—can at all times see the parties on as well as those off duty, either by night or day. Ceaseless toil is but the skepist's dream.

Under like favourable circumstances after many years' obser-

vation we have never had the good fortune to see workers setting eggs, or yet met with any bee-keeper who had. Being so profoundly ignorant of the matter I would be delighted to receive information how it is gone about. Are they carried like pollen? To the supporter of the egg-setting theory I would suggest a little experiment. With a needle remove and set artificially say the lucky baker's dozen, and kindly report the number of chickens hatched. On trial it will be found that egg-setting is easier talked of than effected.—A RENFREWSHIRE BEE-KEEPER.

OUR LETTER BOX.

HOUDANS (J. C. C.).—If you wish to have the strain less dark mate with a light-coloured hen. If the same coloured plumage is wished to be continued mate with a dark hen.

INCUBATORS (J. L.).—We cannot give you any information. Those who make them should advertise them.

AVERAGE FARM CROPS (A. B. C.).—These vary extremely according to the nature of the seasons. On ordinary good land in the midland counties the following may be described as average crops.—Wheat, 4 quarters 2 bushels (63 lbs. to the bushel); barley, 5 quarters (56 lbs. to the bushel); oats, 7 quarters (42 lbs. per bushel); beans, 4 quarters; peas, 3 quarters 4 bushels; turnips and Swedes, 22 to 24 tons per acre; mangolds about 30 tons. As instances of the variation of crops we know land that in 1868 yielded 8 quarters of wheat per acre, the same land in 1876 only producing 2½ quarters. We have also known upwards of 70 tons of mangolds per acre.

PARROT (Cardiff).—Ask your surgeon to look at the lump in the bird's throat. He could tell whether there is matter in it that could be removed by opening the lump.

CHANGING THE POSITION OF HIVES (C. P., Herts).—Let your bees remain where they are till after Christmas, when they may be safely removed. On placing them in another position let everything like a hive or cover of a hive be removed from their present place, and every vestige of the present stand, for if anything of the kind be left some bees flying around their old haunting place may alight on it and be chilled. January we think is the best month for removing bees from one corner of the garden to another.

REMARKS.

- 20th.—Fine pleasant day, but without sunshine.
 21st.—Clear, bright, very fine day; starlight night. [and dry all day.
 22nd.—Clear fine morning, overcast and rather dark after 11 A.M., but fair
 23rd.—Frosty morning and slight fog, sunshine for short time in middle of day, gloomy and cold rest of the day.
 24th.—Wet morning, thick, gloomy, and damp all day; heavy rain at night.
 25th.—Warm damp morning, little sunshine between 11 A.M. and 1 P.M.
 rest of the day dry, but gloomy. [day.
 26th.—Damp morning, rain commenced at 11 A.M., very gloomy rest of the
 Average temperature nearly the same as during the previous fortnight.
 It would have been much lower but for the sudden warmth of the 25th.—
 G. J. SYMONS.

COVENT GARDEN MARKET.—NOVEMBER 27.

WE have no alterations to report from last week. Business quiet.

From observations taken near London during forty-three years, the average day temperature of the week is 47.5°; and its night temperature 30.0°.

ZONAL PELARGONIUMS IN WINTER.

NO class of plants is more valuable for winter decoration than Zonal Pelargoniums, and no plants are more accommodating to the cultivator than they are. No flowers are more showy than these, nor better adapted for cutting purposes, for they last well in a cut state. On the plants for the decoration of the conservatory the flowers continue in beauty for a great length of time. Their flowers indeed are freely produced at all seasons, but are never more welcome than during the winter.

We have watched with much interest from time to time how some growers have weighed Vesuvius in the scales and found it wanting. This variety was at one time highly popular, but now large-trussing varieties are advocated to be grown instead. Why this should be the case we are at a loss to know. We have tried a number of the large-trussing varieties and have certainly found them fall very short of producing the quantity of flowers that Vesuvius does; and further, if we had relied entirely upon those that produce large trusses we should not have had the fine display of bloom we have had for some time past. Vesuvius through the dark and dreary months of the autumn is just as free as it is at midsummer, while the other varieties do not produce their blooms so freely in winter. We have, on plants treated the same in every respect, four or five blooms on the above-mentioned variety to one on the others. Our plants are principally grown in 6-inch pots, and many of the Vesuvius have twenty trusses open on one plant propagated in March last, while the others rooted at the same time have only three or four, and many only one and two trusses. Vesuvius produces its flowers in great profusion, although not so large in the truss, which renders it better adapted for cutting purposes, and they last when cut equally as long as the others.

Our plants are chiefly struck from cuttings and rooted during March and April in thumb-pots, afterwards potted-on as they require more root room until they are placed in 6-inch pots. As soon as all fear of frost is over in early summer, the plants previously well hardened off are placed outside on beds of ashes, and are liberally supplied with liquid manure through the summer, the shoots being stopped and the blooms picked off as they require it. We pot them as firmly as possible in rich fibry loam and sand, adding to the loam a little bone dust. The old plants that we save and repot to grow into a little larger size are rested after blooming for a time; they are then cut back, and after they have well broken they are taken out of their pots and the whole of the soil is shaken from their roots; the plants are then placed in smaller pots, kept close until they take to the new soil, and then hardened off and placed outside, and treated the same as the others. They remain outside until frost compels us to take them in.

An early vinery or Peach house where the trees and Vines have cast their leaves is a good place for them at first, or better still is a light airy house where they can be placed near the glass. As we want them to bloom we introduce

them where the temperature can be kept at 50° at night, which is sufficient to bloom them in; if much lower when the plants are in flower the petals soon damp. We have a sport from Vesuvius which is equally as free as the original, but a little larger in the truss and more of a rosy-scarlet colour; it possesses all the good characteristics of its parent, and is very useful. Wonderful will, we believe, turn out to be a good winter-blooming variety. We have not tried it largely yet, and are not in a position to say much of its merits. If for winter work with its double flowers it is as free as its parent it certainly will be great acquisition; but we shall not discard Vesuvius until we find something better.

The following varieties are worth growing for winter decoration:—Miss Strachan, Mrs. Jacoby, White Princess, Mrs. Hetley, May Queen, Harry Turner, Miss Skipworth, Rainbow, Overall, Mrs. Whiteley, Mrs. Huish, Rob Roy, Mrs. Groves, Mary Pearson, Brutus, Incomparable, Matilda, Mrs. Muster, Lady Emily, Prince of Wales. The latter comes next to Vesuvius for freeness; then Mary Pearson, Mrs. Jacoby, J. Gibbons, a good dark; and Matilda and Lady Emily are good pinks. Many others are worth growing, if not so free, for the distinct shades of colour they possess.—WM. BARDNEY, *Norris Green, West Derby.*

THE TOMATO DISEASE.

BLIGHTED TOMATOES are becoming as common as blighted Potatoes, simply because both of these vegetables are subject to the same kind of disease, arising in each instance from the same causes—a falling temperature and heavy rain; or, in other words, cold and wet. This fact renders the cultivation of Tomatoes in the open air an exceedingly speculative matter, and even when planted against walls there can be very little certainty of securing a crop unless the plants are brought on under glass and have the fruit set by the time the plants are turned out. Then by planting in rich soil, by exposing the fruit fully to the sun, by retaining only enough branches and foliage to insure a quick swelling of the fruit, to promote which bi-weekly applications of sewage or rich liquid manure should be given, we may fairly hope to save the crops before the fatal change of weather sets in during August.

A remedy which will occur to all is to plant under glass. This, however, will prove a delusion and snare if due watchfulness and care be not exercised to exclude cold draughts, especially if dull, chilly, wet weather set in. It was only last summer that I learnt this to my cost, and it may help others if I tell how it happened.

In a long lean-to Peach house many Tomatoes were planted, some close under the glass along the front and others against the back wall between the trees. At one end a considerable space of bare wall was entirely devoted to Tomatoes, and they were so vigorous that they had grown right up to the top 10 feet high, and were laden with large clusters of green fruit. To retard the ripening of some of the Peaches the ventilators were kept wide open along the top day and night, and while this was done the weather became dull and wet, and gusty winds were prevalent. Two

days of this weather with open ventilators led to the total loss of these fine Tomato plants and not a single fruit was saved. Luckily the plants along the front of the house were quite unaffected and afforded an ample supply of excellent Tomatoes, owing, no doubt, to not being immediately under the ventilators, and also to the prompt exclusion of cold draughts as soon as the disease was perceptible upon the wall plants.

Due attention being given, then, to the exclusion of cold cutting draughts, a three-light garden frame or two would afford enough fruit for the requirements of an ordinary family. In such frames it would, I think, prove a good plan to treat the Tomato as a trailer, for from the tendency of the stem and main branches to emit roots I have no doubt they would lay hold of the soil like the Cucumber, and the fruit could of course be readily kept from contact with the soil and exposed to the light on blocks or inverted pots just as Melons are.

Vick's Criterion Tomato proves to be a real acquisition. It is a strong grower and bears abundant clusters of large round fruit, most of it without any indentures, and of a peculiar crimson hue when ripe that renders it distinct from all other Tomatoes. The first batch of plants of it have been in bearing for quite four months, and were so satisfactory that next season preference will be given it for the general crop, with a few plants of Orangefield for early fruit.—EDW. LUCKHURST.

ABOUT VINES.—No. 4.

My Vines were all cut back to within about 3 feet of the base of the rafter to commence the second season. They broke strongly; and, as I think a certain index of health, they were thickly clustered with gummy globules. To let well alone I have since learned is the best practice, and if I had acted on that principle at that early stage of my experience I undoubtedly would have escaped several mishaps.

The first misfortune was with guano. I had been told to put it in the pans on the hot-water pipes. A few days after I observed that the foliage was being injured, and at the first opportunity drew a gardener's attention to the injury. The consolation I got was the remark—"Oh! but you have not kept the pans full of water." Of course I had not. I had never heard of the necessity; and then learning to reap any advantage from guano so used it was necessary to keep filling the pans, I have not used any in the pans since. To water with guano well diluted, which I afterwards did, is safe practice; and perhaps the less ammonia arising from the border is not injurious and may be beneficial, but I have had no guano this season. I still had a hankering after the fumes of ammonia, of which I had read so much, it being advised as deterring to red spider; and I concluded I would make one more trial to have those fumes which Vines delighted in and spider abhorred. I had some fresh cow manure, and mulched with it about 2 inches thick. One end of theinery I covered it over with burnt wood ashes, and the other end for the first night I left it uncovered. I thought I had enclosed plenty of ammonia, but I never had the least dread of injury. The next morning a portion of the fine dark healthy foliage was hanging, where the manure was uncovered, like Rhubarb after a frost. These leaves I removed by degrees, taking off those most injured at once.

In the middle of July a friend pointed out two Vines on the back wall which were slightly attacked with red spider. The news seriously alarmed me, but then I had read of a certain cure with sulphur. So long as the sulphur only boiled upon a heated brick or shovel I had understood there was no danger; and, moreover, I had read somewhere that sulphur was certain death to spider. Previous misfortunes made me rather cautious, but if the spider was certain of suffering before the foliage the task was easy enough. Armed with a magnifying glass, the better to observe the effect upon the enemy, I procured a leaf with some spider upon it, and set to work with the hot bricks, each brick being tested with the sulphur before being brought into theinery. To my surprise, instead of the sulphur fumes killing the spider, it only made the little pests move all the quicker, and I held them pretty close to the bricks. After doing twelve Vines on the back wall, I thought me that another night would answer the same purpose, and that I had better leave off to see how the experiment answered. The sight the next morning alarmed me. The leaves of the twelve Vines were nearly all black, and the truth is I was near despair. But the most galling thing was, on bits of green left on the Vines affected there was the spider as live as before. I then removed the leaves hopelessly dead, leaving

those partially injured, and this year I had an abundant crop of fruit. In a few days the spider disappeared, and I have not seen one in the house since. My firm belief is, if you commence when thinning to paint the hot-water pipes with plain sulphur and water, and keep your Vines reasonably healthy, no spider will injure them.

I will conclude here about Vines at present, but if anything should occur that I consider of service to the readers of this Journal I shall only be too glad to return to the subject another time.—JOSEPH WITHERSPOON, *Chester-le-Street*.

TEA AND NOISSETTE ROSES.

I CANNOT conceive why anyone should wish to write down such a beautiful and fragrant Rose as Gloire de Dijon, unquestionably the finest Tea Rose in cultivation for every purpose. The commonness of this Rose is, I think, its only fault, if that be a fault, for I apprehend what makes a Rose very common is its ability to withstand every vicissitude of soil and climate, coupled with so much beauty that everyone likes to see it, and therefore everyone grows it. It has such a scent, too, that a basket of it is always welcome in a room, and to hospitals, infirmaries, and invalids in general it is a boon that cannot be replaced. What other Rose can replace it? None other, for it has no equal. Give Gloire de Dijon the same treatment that the other exhibition Roses receive and it will not disappoint you. It is too often allowed to exhaust itself with blooming, and seldom receives proper attention, in many cases none whatever; but unkind treatment will not kill Gloire any more than unkind words will make one plant of it be grown the less; it is of too good a stamp for that. Give honour where it is due, and think of the Roses we should be without had Gloire de Dijon never come to light. But the more we think of it the more we must honour it. Gloire has not won its fame in a season; it is an old and tried friend, seldom absent from its post, the delight of thousands, loved and cherished by us all, and I fear it will not be in the lifetime of any of us that so good a Rose will be raised again.

About Maréchal Niel I have nothing to say. "HEREFORDSHIRE INCUMBENT" says it is the grandest of all Roses, and I agree with him. Would that it had the hardihood to bear our climate. I object to the laudation of Madame Berard both by "WYLD SAVAGE" and "HEREFORDSHIRE INCUMBENT." I admit its fine copper colour and its vigour, but it will never become popular like Gloire de Dijon, it is too shy a bloomer for that. One plant of Gloire will give more blooms than a dozen of Madame Berard, and in my opinion superior blooms both for show or any other purpose. Madame Berard has no scent—a fatal objection to its ever becoming popular, and one that ought to carry some weight even for exhibition; for what is a Rose after all without scent?

I would suggest to "HEREFORDSHIRE INCUMBENT" that instead of naming Souvenir d'Elise twice he substitute Jean Pernet; it is a grand colour, but it needs more substance. Céline Forester is also worth a place, as it is one of the very best Roses for all purposes—vigorous grower, fine colour, richly scented, and an excellent autumn Rose. It is no doubt rather small for exhibition, but I have seen it very fine. Mr. Charles Turner always shows some grand specimens of it in pots. Is your correspondent correct about Madame Riza du Parc? It may be, as he says, the finest Tea Rose sent out for some time, but I do not like its colour, it seems to me to have no purity. It is a very good grower, fine habit, and if I am mistaken about the colour it will be a great addition. Madame Margottin is a fine Rose, but with me it has a bad habit of coming with double centres and ill scent. Why is Cheshunt Hybrid omitted? Because it is not a true Rose? Will it not be allowed to compete again as a Tea? I am sorry many of those mentioned by "HEREFORDSHIRE INCUMBENT" will not bear the Yorkshire climate; they may do so in exceptionally good situations. Homère I find is one of the hardiest, generally small, but sometimes very beautiful; unfortunately it has no scent.—F. BOYES.

EUCALYPTUS GLOBULUS.

I BELIEVE the largest Eucalyptus globulus growing in Ireland stands within the walls of the vegetable garden at Johnston Castle, Wexford, the seat of the Earl of Granard, K.P. Its height is 42 feet, circumference at 1½ foot from the ground 37 inches. When planted nine years since it was between 4 and 5 feet high. It was raised from seed there, and has con-

tinued to flower and ripen seed in abundance during the past four years. There is at present a quantity of fine young plants raised from the produce. I have no doubt its proximity to the sea (five miles) has influence over its existence. They are planted both on loam and peat. On the latter they have doubled the others in height. They are planted in open spaces but not exposed.—R., *The Gardens, Castle Forbes*.

GARDENING OF THE PAST.

ABOUT 1820 I remember that those who took pride in their gardens were in possession of many useful species and varieties of plants and fruits, which afforded them many hours of pleasure amidst the turmoil by which they were surrounded. Even in fruits there were several varieties that are still in the first ranks of the lists. Ribston Pippin Apples were grown at that time, and Keswick Codlin and Hawthornden were just coming into note, the latter fruit free from specks and produced on trees free from canker. Jargonelle Pears had a place then, and so had Green Chisel, the latter the especial favourite of schoolboys. Green Gage Plums were to be had also, and certainly May Duke Cherries were quite as good at that time as they are now. Gooseberries were general favourites, and it is interesting to remember that some of the varieties now extensively grown in the south of England to supply the requirements of the great metropolis were known at the time spoken of. Rifeman, Crown Bob, Ploughboy, and Lancashire Lad were especially popular. Strawberries had not been neglected, for good crops of Hautbois were oftener met with than then now, and Keens' Seedling was not unknown.

Turning to flowers, my memory points back to a time when many cottagers' gardens possessed rows of the double yellow Primrose as edgings to paths. These Primroses were plentiful about 1824, but about a dozen years ago I had some difficulty in obtaining a plant or two of this favourite old sort. Double Daisies were largely grown; Auriculas were also cultivated, and very good Polyanthus by those who made the plant a specialty. Stocks were very popular, and would certainly contrast favourably with the Brompton and East Lothian varieties now in vogue. Double and single Wallflowers were also in fashion; one of the most popular amongst them was the pale double yellow. The dwarf double white Rocket was a great favourite rarely seen now. The old double yellow and white Batchelors' Buttons were common then and contrasted favourably with many things that are fashionable now. Pinks and Carnations occupied a prominent place, and a bed or more of Tulips, and, if the soil suited, Ranunculus also. Hyacinths were not such great favourites, and Crocuses found a place in patches amongst the flower borders; and the most showy ribbon border I ever beheld was one formed entirely of Crocuses of different colours that had stood several years in the same position.

The Dahlia came prominently into notice soon after 1826, first as a single flower, then semi-double, and eventually double. Springfield Rival was the first important double flower that had a long reign, for it was grown through the most important period of the Dahlia's popularity, say from 1835 to 1845. The Pansy also had its admirers, and its rise as a fancy flower was even more rapid than that of the Dahlia; but the introduction of the zonal Geraniums, the Verbena, and other plants into flower beds between 1835 and 1845 revolutionised the whole system of the flower garden, and it is to be regretted that some of the old flowers have been much neglected since, notably the blue varieties, or perhaps species of *Anagallis*, of which there used to be fine beds of healthy compact plants about 1840; now it has degenerated merely into a name amongst annuals. After the bedding period set in Tulips and Ranunculuses and some other flowers lost their positions, but Pinks and Carnations retained their ground. Roses were favourites then as now. I can carry my memory back to fine rows of that most superb old Rose the York and Lancaster, than which I know of nothing at the present day to compare; also Moss Roses and the old Tuscan and the common bluish China to cover walls, &c., were plentiful. The first worked standard Rose I ever saw had more attractions than any I have seen since, for it had three or four varieties all worked upon it and all in flower at the time, the common China and a pale Moss being two, while the old French White yields to none at the present day for sweetness.

Our gardens are now enriched with many things our elders never possessed; still we must not deny them the merit for what they had done, as they bequeathed us a host of useful

plants the beauty of which still forms so important a feature in our gardens. We must not despise what was done in the olden times, when such shrubs as Lilacs, Laburnums, Rhododendrons, Camellias, Myrtles, Laurustinus, &c., were introduced, and which will long retain a prominent place amongst our cultivated plants.—J. ROBSON.

DECORATIVE USES OF CONIFERS.

IN a preceding number of the Journal Mr. Wright called attention to the usefulness of Conifers, hardy shrubs, &c., as winter-bedding plants. Messrs. Veitch's grand and suggestive collection staged at South Kensington on October 15th not only looked attractive as arranged in baskets, but the shrubs would look equally well if bedded-out during the winter and the summer months. This all who have seen the two large beds filled principally with this class of plants in the grounds of the Crystal Palace will, I think, readily admit; therefore I would suggest the advisability of having permanent beds of small Conifers, &c., somewhere in the ground, which, if tastefully arranged, would attract much attention at any time, for the shrubs, &c., referred to are emphatically fine-foliaged plants.

There have of late years been many fresh introductions of Conifers, some of which are decided acquisitions and deserve to be better known than they are. What adds to their value is their extreme hardiness, which admits of their being grown in many places where the more expensive luxury of a stove is not indulged in. Some of the varieties of Conifers are not perfectly hardy; these, however, may be grown in pots or tubs in a cool house, and not only these, but others of known hardiness may be similarly grown, and they with very little trouble will be found to give quite as much pleasure as most kinds of tender plants. During the summer months specimen Conifers are extremely useful for standing in groups or singly on wide paths, drives, terraces, &c., or plunged in suitable places in the turf. Instead of Conifers we frequently see in front of villas, &c., miserably grown Pelargoniums in large pots, which look anything but attractive. Of course in large places where Conifers are extensively planted out there is not so much necessity for keeping them in tubs. In places of limited extent, if the plan of growing them in tubs is followed and ordinarily fair treatment given, a great variety of attractive specimens may be had which anyone might be proud of owning.

Tubs are preferable to pots for Conifers on account of the latter, unless plunged, being liable to be broken by frost, and also tubs do not absorb the moisture from the soil to such a great extent as pots do when exposed to solar heat. Fair-sized (medium-priced) plants should be started with, using tubs 18 inches in diameter and 17 or 18 inches deep, and these look extremely well "oak-grained," the iron hoops and handles being painted black. No particular mixture of soil is necessary; two parts of turfy loam to one of leaf or peat soil, with a light addition of sand and decayed manure, will grow them well. Failing this, the best garden soil obtainable may be used; to this should be added, if rich and heavy, broken crocks, mortar rubbish, or sand in sufficient quantities to keep it porous; if light and poor a good quantity of old manure. Good-sized pieces of crocks or mortar rubbish may be advantageously used in any kind of soil, as they not only keep it open, but also help to keep the roots from too quickly penetrating to the sides, thus utilising the whole of the soil. The tubs or pots should be carefully drained, the plants well and firmly placed in them, and the soil should never be allowed to become dry, as Conifers, I believe, have their root-action constantly on. The tubs should be raised on blocks or bricks, as the tubs will then last much longer and will be also out of the reach of worms, which are apt to take possession of them much to the plants' injury, especially in the early stages of growth, before the roots have fairly taken possession of the soil. When the plants are well established an occasional dose of liquid manure will be very beneficial to them, and, in fact, is almost indispensable when they have to remain in the tubs some years. Messrs. Barron & Son, Borrowash Nurseries, near Derby, have of late years exhibited Conifers in tubs successfully at the great horticultural shows. At Preston they gained the first prize, staging good plants of the following, the names of which I append and also a few brief notes taken on the ground:—

Abies Parryana (native of Colorado).—The hardiest of the Spruce Firs. Is very glaucous and attractive.

Abies Alcockiana (Japan).—Of good habit, very hardy, ornamental, and free-growing. The under side of the leaves

is very glaucous, and they remain on the trees for several years—an unusual feature.

Abies polita (Japan).—Very distinct, hardy, robust, and free-growing. Leaves bright green, which stand out boldly, and these, too, remain on the trees many years.

Abies Pattoniana (California).—A distinct and handsome species of the Hemlock Spruce section, which is not so generally grown as it deserves to be.

Arthrotaxus selaginoides (Tasmania).—This belongs to a genus generally considered too delicate for this country, but this species has proved itself perfectly hardy. It is very distinct, of a fine golden tint. No collection is complete without it.

Abies (*Tsuga*) *Sieboldii nana*.—Probably the most distinct of this section. Naturally dwarf and graceful. It is very hardy and rather scarce.

Cupressus Lawsoniana lutea (garden variety).—Of free-growing dense habit, and probably the best golden-coloured Cypress extant.

Dacrydium Franklinii, the Huon Pine (Tasmania).—A very interesting and distinct species, the growth of a beautiful green colour, very pendulous, and graceful. Well adapted for crowning or planting in rockeries.

Picea magnifica (California).—Somewhat resembling *Picea nobilis*, but is more robust and of greater value from the fact of its being about a month later starting into growth, thereby escaping the May frosts, which are frequently so disastrous to this section of Pines. The timber of this species is known to be the best of this section.

Picea bifida firma (Japan).—Of unusual bold foliage, and is an excellent and distinct variety. This, too, is, like the preceding, about a month or six weeks later starting into growth.

Pinus Jeffreyi.—Considered one of the best of the Californian Pines, is handsome, and the constitution good. Foliage of a pleasing bluish green.

Podocarpus alpina (Tasmania).—This genus is not generally considered hardy, but this species, however, is probably the hardiest, and is but little known. The Yew-like growth is naturally pendulous and is very attractive.

Retinospora plumosa aurea (garden variety).—One of the best Golden Conifers. Well adapted for nearly any position or use.

Retinospora plumosa argentea (garden variety).—Of dense compact growth. The tips of the branchlets are white. A very hardy and effective variety.

Retinospora filifera (Japan).—As the name implies, the branchlets are like so much whipcord. Is perfectly hardy, and is very effective planted in rockeries.

Sciadopitys verticillata (Japan).—This is better known as the Umbrella Pine, so called from the umbrella-like disposition of its leaves. It is a remarkably distinct variety, but unfortunately of doubtful hardiness; it is, however, becoming more acclimatised, and doubtless will succeed in well-drained and sheltered positions. In Messrs. Veitch's Coombe Wood nursery it thrives exceedingly well, never failing to attract the visitors' attention.

Taxus Dorastonii aurea (garden variety).—A variegated form of the Dovaston Yew, remarkable for its almost regular tiers of decidedly pendulous branches.

Taxus adpressa (Japan).—A distinct and highly ornamental Yew with very short dark green leaves.

Taxus baccata aurea (garden variety).—A very hardy and free-growing golden Yew. Easily trained into various shapes. Many remarkable examples of pyramidal and other modes of training this variety are to be seen in the grounds at Elvaston Castle, Derby, some of which may be correctly described as resembling pillars of gold.

Thujaopsis dolabrata (Japan).—Considered one of the most beautiful of evergreen trees. In most districts perfectly hardy. Of good pyramidal habit; the foliage deep green, very elegant, and of great substance.

Among the one hundred hardy plants exhibited by the same firm at the Preston Show there were a few newer and very attractive varieties of Conifers, which will eventually become very popular. These included nice plants in pots of

Retinospora tetragona aurea (garden variety).—Considered the loveliest of all the *Retinosporas*. It is of moderate growth, well furnished with horizontal branches, tufted at the extremities with tetragonal or four-edged pendant branchlets of a beautiful golden colour, which in time change into a deep green—a strong proof of a good constitution.

Retinospora obtusa compacta.—An excellent variety for pot culture or small gardens.

Picea concolor (Colorado).—A new hardy and distinct species. The leaves are long and of a beautiful glaucous blue.

Cupressus Lawsoniana pyramidalis alba spica.—Considered the best silver-variegated Conifer; no collection complete without it, and

Cupressus Lawsoniana lutea (new garden variety).—Of free-growing dense habit, and probably the best golden-coloured Cypress extant. This and preceding variety are perfectly hardy.

Chamaecyparis sphaeroides aurea (new garden variety).—In the way of *Cupressus Lawsoniana lutea*. Colour very good, habit compact.

Taxus baccata Elvastonii aurea.—This is a very distinct variety of a bright orange self colour, which it retains to a remarkable degree during the winter. It is a sport from the common Yew, and the original branch is still to be seen growing vigorously from one of the many remarkable clipped specimen Yews at Elvaston Castle.

Wellingtonia gigantea lutea.—A sport from the *Wellingtonia gigantea*, possessing most of the good qualities of that variety, in addition to which the young growth is very golden, changing in late autumn to a beautiful green, consequently is perfectly hardy.

All the varieties mentioned are undoubtedly well tried and selected from the almost innumerable varieties of modern introduction, and offer an equally good selection either for tub culture or for planting out on lawns, &c.—W. IGGULDEN, Orsett Hall.

MARÉCHAL NIEL ROSE—DISBUDDING.

MARÉCHAL NIEL and many others of the class do well worked as standards on the Briar in the open, and if the branches are tied back or downwards plenty of blooms will generally be obtained, and those on the Maréchal being pendant will be well protected and shaded. Many complaints have been made that this Rose when worked on the Briar goes off after a few years, and ultimately dies, the apparent cause of failure being a peculiar cankered swelling at the junction of the bud with the stock, and which I attribute to the inability of the roots of the Briar to keep up the great quantity of the particular nourishment requisite for the healthy maintenance of the Maréchal when fully bloomed. I have never seen the defect with this variety on its own roots. A like premature end, however, attended Maréchal Niel, which I double-worked on the vigorous and hardy Noisette America, with a Briar root. The Maréchal went off as usual at the junction, but the portion of the stock supplied by America was sound and healthy. Doubtless exhaustion, caused by the overflowering of the Maréchal, has something to do with this failing; and when the immense number of blooms which a single plant is sometimes allowed to carry, and the weight of each bloom and the multitude of large petals it contains is taken into account, it is not surprising that the drain should be inadequately met by the roots of an artificial stock. It may be urged that the massive blooms of Gloire de Dijon are almost as exhausting, and so they are, and when the old Rose is worked on the Briar it in time exhibits a similar failing, although not so early as the Maréchal nor in so marked a manner; but there is this difference between the two, that whereas Maréchal Niel has one principal blooming period—usually in spring, and draws excessively, and at one time on the roots, and perhaps before the root-action of the Briar stock is in full play—the blooming of Gloire de Dijon is more distributed over the whole year.

Surely those who would prohibit the disbudding of Roses for show would hardly extend their doctrine to Noisettes, and especially to such varieties as Triomphe de Rennes, Lamarque, &c., which in many seasons cannot properly open all the buds they show, and even when they are able to do so it must be at the cost of permanent injury to the plants. My advice to growers of the Maréchal and all over-blooming Roses, if healthy plants and good blooms are wanted, is to disbud, removing all irregularly formed and ill-placed as well as many of the smaller buds. Theorists lose sight of the fact that Nature to some extent provides a remedy for this in "the worm in the bud," and whose uncertain work the zealous cultivator attempts to counteract. Setting aside the question of beauty and appearance, which at least is a matter of opinion with exhibitors, the carrying out of such a stringent rule as the prohibition of disbudding would be impracticable, for if the practice be resorted to at an early stage it is almost impossible for an experienced eye to detect it at the time of

exhibition or to distinguish between the work of the cultivator and that of his insect friend (or his enemy), or of Nature, which frequently enables an overworked Rose to throw off some of its buds. I am, however, diverging too much from the main subject of my paper, and would just add that if planted in a south aspect Teas and Noisettes will be all the better for good mulchings of rotten dung at the fall, and again in April when the buds are formed, in order that the roots may be kept from the hot sun and extreme temperatures. The necessity for this is too often lost sight of, and Tea Roses, although they require a good ripening of the wood and sufficient sun for the purpose, do better when the roots are kept cool. It will be found that those planted on the north side of a fence and trained over the top do better and flower as well as those on the south side. I have frequently seen a vigorous and healthy Rose with the roots almost entirely under a hard or paved yard or roadway, where scarcely any heat can penetrate, and where the evaporation must be but slight, and the supply of air, moisture, and continuous nourishment for the roots can be obtained only very indirectly. I do not, however, recollect ever having seen a Rose do well where the roots were similarly placed under grass, which is far too exhausting, and deprives the underlying roots of both nourishment and moisture. Another good position for the more vigorous and hardy Teas or Noisettes, such as Céline Forestier, Gloire de Dijon, Climbing Devonensis, Triomphe de Rennes, Belle Lyonnaise, Rêve d'Or, &c., is to them the shelter of an old leaf or rubbish pit, the sides of which will afford protection to the Roses; these if allowed of run wild will often equal the Briar and the Bramble in vigour, and their natural beauties will be displayed in an unparalleled manner. Finally, in acknowledging the scarcely merited compliment paid to the brilliancy of my Roses by your worthy correspondent, I would repeat what I have previously stated in your pages—that I believe this brilliancy of colour, especially amongst the reds, is in some measure due to the presence of lime and a warm soil.—T. LAXTON, Bedford.

GARDEN AQUARIUMS.

HAVING discussed the question of the most suitable plants and fishes for small ornamental ponds, it now only remains to add a few words as to some of their accessories.

When the margin of the pond is nearly level with the surface the turf may be carried right up to it, and this will prove a beautiful and simple arrangement. When, however, the margin is raised a foot or more upwards a rockwork well filled with soil in the interstices may be raised against it, projecting an equal distance outwards at the base, and in this case a better finish will be given by surrounding it with a narrow gravel walk. In furnishing the rockwork simplicity should be aimed at, it being remembered that this is merely the bordering of a more important central object. The selection will therefore be chiefly made from small plants, such as Sedums, Saxifrages, and the like, to the exclusion of large Ferns and tall-growing plants, which would scarcely harmonise with the position.

To give a detailed list of all that could be utilised would be equally tedious and unnecessary; I shall therefore offer only one more illustrative selection, such as I have found very effective during the past summer.

I made the Sedum acre the basis or groundwork of the whole arrangement. This lovely though common species, which may often be seen in country villages glorifying with its rich bloom the old thatched cottage roof and farm buildings, is invaluable for our purpose, giving effective masses of green foliage throughout the year, and a vast profusion of rich yellow flowers lasting for a month or six weeks in the height of summer. Equally valuable is Sedum glaucum, the tufts of which form turquoise green cushions which mould themselves to the rockwork and form an effective contrast. Sedum Lydium, again, has much the same habit of growth, and forms a bright relief of emerald green with red variations. The single columnar stems of Sedum montanum render it available for any odd nook, where it produces late in summer large terminal blossoms. The variegated foliage of Sedum acre elegans, the white blooms of Sedum album, the large yellow flowers of Sedum grandiflorum, and the pink and whitish blooms of Sedum kamschatkianum render them all valuable additions interspersed at intervals.

A few Sempervivums, such as *S. californicum*, *S. tectorum* (or the common Houseleek), and *S. arachnoideum* may be inserted here and there; while of the Saxifrages a fair selection

will include *S. nepalensis*, *S. pyramidalis*, *S. pinnatifida*, *S. Aizoon compacta*, *S. hypnoides*, and *S. rosularis*. I must not omit pointing out the value of *Saponaria calabrica*, a creeping plant of free growth, which yields a long profusion of small pink flowers during the summer. A few tufts of *Rhodea japonica* are effective at intervals, and if space permits the miscellany may be completed with such forms as *Arabis albidula*, *Antennaria tomentosa*, *Aubrietia purpurea*, *Veronica incana*, and I had almost forgotten the common London Pride.

The plants named if judiciously arranged on rockwork form an appropriate margin to a miniature ornamental pond in an exposed position, and contribute much to the attractions of a "garden aquarium."—J. P.

FORCING VEGETABLES.

POTATOES.

NOW is a good time to make preparations for forcing Potatoes in frames, but as I referred to this matter some time ago what I have to say now will only be a brief reminder. Leaves, which can be had plentifully now, and a little littery manure, will supply the requisite heat. These should be thrown together in a heap and allowed to lie for a week. During this time clear out to the depth of at least 3 feet from the glass the inside of the frame in which the Potatoes are to be forced; fill up 2 feet of this space with the leaves and dung trampled as firmly as possible, then cover with 8 inches of light soil; plant the Potatoes in this 6 inches apart in rows 15 inches asunder; place on the lights, and little attention will be required for some weeks excepting on fine days, when a little air may be given. Rivers' Ashleaf is the sort we force most of. Planted from the beginning to the middle of December they are ready at Easter. Small frames 6 feet wide are suitable, but, of course, any much wider answer equally well. The lights should be securely covered to exclude frost, and provided this is only kept out the bottom manure will do the work of bringing the crop forward.—A KITCHEN GARDENER.

ASHDOWN PARK,

THE SEAT OF F. C. THOMPSON, ESQ.

OF the many new mansions that have been built in Sussex during the last decade that in Ashdown Park is one of the most remarkable for its snug sheltered position, its massive style of architecture, and the imposing aspect of its southern façade. The front terrace slopes down to a piece of ornamental water, with a wide stretch of grass land beyond, rising gently to an enclosing belt of Scotch Firs. Behind, on the north side, a somewhat steep slope affords a sunny site for the walled kitchen garden, and an outer unenclosed space for the culture of vegetables and for various useful glass structures, all well sheltered by a thick belt of trees, which covers the side of a hill so as to break the force of gales from the north or east.

As I came near the garden from the principal entrance a Peach house against the outside of the east wall attracted my attention, not simply as the most conspicuous object in sight, but by its singularly light and elegant appearance. It is a curvilinear lean-to of iron and glass 11 feet high, 7 feet wide, and 155 feet long, thoroughly ventilated, having hot-water piping to exclude frost, so that a shelf some 2 feet wide along the front can be turned to account for plant culture all the year round, the whole of the trees being trained to wires strained closely along the wall. They were in good health and vigour, and the crop of fruit was abundant both of Nectarines and Peaches. I was glad to find the Old Roman Nectarine well laden with fruit, and a favourite. I do not, however, recommend it, as we have now so many new sorts that are superior to it. Of these growing near it Lord Napier had plenty of large highly coloured fruit, then in full use, for it was in August that I made my call; Pitmaston Orange had a full crop of larger fruit than one often meets with of that excellent variety, owing no doubt to the bountiful supply of liquid manure which Mr. Down told me he was then giving the border twice weekly; Victoria Nectarine also had a heavy crop, and is much valued for its late period of ripening. Of Peaches Early Beatrice was finished, most of the fruit having been used in July; Rivers' Early York, affording a prompt succession of its handsome rosy fruit; a Grosse Mignonne with some three hundred fruit gave ample promise of carrying on the supply, with a Barrington remarkable for its large green foliage and fruit of proportionate size, and other kinds to follow. It was calculated that the crop of fruit would amount

in the aggregate to two thousand, or something like twenty fruit daily for a period of three months; and the vigorous condition of the trees gave ample promise of an equally fine crop next year. The upper end of this house is several feet higher than the lower, and I was told that in winter when the pipes are heated the upper end is apt to become too hot while the lower is comparatively cold. To counteract this fault in this and other houses partaking of its peculiar character, I may suggest that piping need only be taken from the lower end up half or two-thirds of its entire length to generate sufficient heat for the whole, the heat being quite certain to ascend to the upper end with sufficient promptitude to exclude frost however severe it might be.

The other glass houses consisted of a span-roofed conservatory on an elevated plateau near the house, with sloping banks below planted with Clematis and other choice trailers. A central stage and side shelves contained a creditable collection of plants of the ordinary type, Vallotas, Liliums, and Begonias being all well represented, while the roof was gay with lovely clusters of the delicate blue flowers of *Plumbago capensis* and the deep crimson waxen clusters of *Habrothamnus elegans*, a great favourite of Mr. Down's, and deservedly so, for it is undoubtedly one of our best greenhouse climbers, continuing in bloom throughout the year. Two vineries in the kitchen garden contained heavy crops of Grapes, which for size of bunch and berry and for finish were quite in keeping with the magnificent crop of fruit in the Peach house. Flourishing young Camellias were being trained up the back walls, and some few of the numerous flower buds were already beginning to expand, which was doubtless owing to the premature growth annually excited by the heated air in which they grow. Upon the sound policy that plenty of heating surface is true economy each house had six rows of 4-inch piping, and I strongly commend this matter to the notice of everyone engaged in the construction of new vineries, and may also usefully point to the importance of letting the pipes stand out clear from all walls as well as being raised a few inches from the floor.

Pits, frames, and a little stove all afforded a pleasant sight in the clean healthy condition of their occupants. Cream Pine Melon was fruiting well, so were some plants of Telegraph Cucumber, which latter I commend to the notice of such as find Cucumber culture a difficult matter, for they were growing in an ordinary garden frame, and had afforded an unfailing supply of fruit since April, a fruit having been cut regularly every alternate day, and a goodly number at other times. "To what do you attribute your success?" was my question. "To a regular daily attention to every apparent want of the plants," was an answer which is quite worth recording here.

The kitchen garden was remarkable for its good vegetable crops and its trim neat appearance, to which the firm walks of tar concrete materially contributed. Other walks were in course of construction of this substance, and I gladly seized the opportunity to watch the process for my own instruction and the benefit of my readers. A heap of building debris, consisting principally of sandstone, had been broken as if for a road; on this heap coal tar had been poured in the proportion of one part of tar to three of sand; it was then turned over, well mixed, and would be left afterwards lying in a heap for two days; lime would then be added and mixed with it in the proportion of three bushels to twenty or thirty bushels of the tarred sand; it would then be spread upon the paths 2 inches thick, and at once pressed carefully down with a roller, sand being first sprinkled over it if prove at all sticky, or better still some small sea-beach pebbles, which impart a better appearance to the surface.

Among the vegetables a large bed of Cauliflowers was worthy of especial notice. The seed was sown on the 10th of April, the sorts being Walcheren, Carter's Mont Blanc, and Veitch's Autumn Giant. The two first were then (August 22nd) coming into use, and would afford a supply till the Autumn Giant was ready, which in due course would be followed by Veitch's Autumn Broccoli, which Mr. Down finds decidedly later than the Autumn Giant Cauliflower, and then for midwinter Snow's Broccoli comes into use.

The outside of the west garden wall was devoted entirely to ornamental climbing plants, and was certainly an agreeable and striking sight, being well covered with a mingled growth of Clematis, Ceanothus, Cotoneaster, Escallonias, Bignonias, Pyracanthas, Magnolias, and Glycine, with numerous Fuchsias forming a charming fringe of green and crimson along the bottom of the wall, and some Hops embowering an arch over

a door. Narrow borders of hardy perennial flowers fringe the garden walks, Phloxes and Fuchsias being pleasingly conspicuous, and among numerous pretty plants some yellow Oxalis told well with rich deep crimson tufts of *Linum rubrum grandiflorum*, and a very dwarf dark velvety-flowered Scabious called *nana flore-pleno*.

The terrace lawn had well-filled flower beds, on which I need not dwell, except to notice and commend a bed of mixed Fuchsias as being quite as charming an innovation as the beds of Begonias which I have seen in a few other gardens.

The collection of shrubs is a good one—pleasant to behold, because all are in a flourishing condition. Special care has been devoted to the planting, every shrub or tree having had a little rich soil placed round the roots to give it that successful start, to which secure staking to prevent mischief from wind till the roots have laid well hold of the soil also contributes.

The garden is not a large one, but it is eminently worthy of commendation for the skilful culture and painstaking care evinced in every department, and I heartily congratulate Mr. Down on work so well done and abilities so well applied. —E. L. O.

DRESSING CARNATIONS.

INCONTESTABLE evidence of the power of dressing flowers in winning prizes has been adduced. If I am the best grower of Carnations in England, and I obtain previously to the exhibition the aid of the best dresser, I can then compete in many more classes than I possibly could do if I had not been so aided; that is so if I happen to be a bad dresser, and much more so if I am a good one. In such a case the novice introduced on page 404 by Mr. Dodwell would manifestly exhibit at a great disadvantage; indeed except under those conditions I fail to perceive that he would have cause for complaint. I have placed the matter so as to show the unfairness of the practice in question, and am as far as possible from suggesting that Mr. Douglas would knowingly take an unworthy advantage of any competitor. No one has less reason to do so than he has, and it is simply impossible in my opinion that anyone who is free from prejudice can defend a practice of the nature indicated when its full scope is appreciated.

I have not read the rules of the National Carnation Society, but I readily accept the word of Mr. Douglas that he has not infringed them; but surely that does not prevent me challenging a practice that I consider seriously objectionable. If a precedent is necessary for such a course I can produce one. When Mr. Douglas protested, in much stronger language than I have employed, against an exhibitor who defeated him with Hyacinths, the said exhibitor did not infringe any rule. According to the conditions of the Society he was legitimately entitled to the prizes, although another had aided him in obtaining them; but that did not, and properly so, prevent the strong protest referred to.

I need not discuss the subject further. I have never won a prize with flowers dressed by another hand than my own, and I never shall. Mr. Beachey has placed the matter in its right light, and there I leave it. I have not in this controversy thought of ascribing an unworthy motive to anyone, knowing that such a course would have weakened, not strengthened, my position. I close with a prediction that the time will surely come when public opinion, in spite of old authorities, will compel exhibitors to dress all their own flowers.—A STAFFORDSHIRE GROWER.

EXHIBITING CHRYSANTHEMUMS.

In your report of the late Chrysanthemum Show held at the Westminster Aquarium on the 19th inst. I observe that you describe the flowers in the stand from Liverpool as having been "hideously set up with ornamental papers underneath each flower." Many growers in this neighbourhood think that if it is considered bad taste to set up flowers on ornamental papers the matter might be discussed in a friendly spirit, and let growers both north and south be made aware that the practice, if wrong, should be done away with. It has been the custom in Liverpool for many years to exhibit Chrysanthemums on ornamental papers, and London judges have not yet complained of that mode of exhibiting.—W. TUNNINGTON, *The Gardens, Calderstone, Liverpool.*

EARTH WAX.—AN account of this wax, scientifically known as ozokerit, which is mined in the Austrian province of Galicia,

appears in the number of the "Proceedings" of the American Chemical Society. This substance occurs at depths ranging from about 160 to 320 feet below the surface, in certain petroleum-bearing strata, along the northern foot of the Carpathian Mountains. It is found in lumps or layers from 1 to 3 feet thick, and is of a pure honey-yellow colour, with the hardness of beeswax. The better qualities of this earth wax are manufactured into ceresine, a substance hardly distinguishable from beeswax, and sold as such in Russia, to which country large quantities are exported.

GROS COLMAN GRAPE

ALONG with this I send you a medium-sized bunch of Gros Colman Grape, it being one of thirteen bunches on one rod growing in our Muscat house. It is sent for your opinion, and under the impression that this grand late Grape has not yet, and never will, take its proper position until it is cultivated in a high Muscat temperature, under which circumstances it is found here to very far surpass the quality of any that have been produced in a Black Hamburgh house. It is not now so "well up" as it will be six weeks hence; but I think you will, to say the least of it, find the sample sent much superior to the character generally accorded to this noble Grape as regards flavour.—D. THOMSON, *Drumlanrig*.

[The bunch of Gros Colman which we have received from Mr. Thomson is the finest of that variety we have ever seen; large and handsome, weighing 3 lbs. 14 ozs., and with berries some of which measure $1\frac{1}{4}$ inch in diameter, as shown in the engraving of them. The bunch sent to us shows how well this valuable Grape can be grown, and how desirable it is that it should be more extensively and better cultivated than it has been hitherto. A native of the East, it requires a temperature equal to that of the Muscat of Alexandria, and with this treatment Mr. Thomson has succeeded in establishing the reputation of this Grape, hitherto much reviled by those who did not know how to grow it.

The history of Gros Colman appears not to be very well known, and a question has lately arisen as to the correct orthography of the name. It was introduced to this country from Angers by Mr. Rivers about twenty years ago, and, as he informed me, he discontinued growing it because it did not ripen in a house where Black Hamburgs were grown. It was subsequently introduced by the late Mr. Standish when he first went to Ascot from M. André Leroy of Angers, and as he treated it as a late-ripening variety requiring a great amount of heat he succeeded in ripening it perfectly. The bunches were small and cylindrical, closely set with large black berries, but in no respect approaching the one that is now before us. Mr. Standish always spoke in high terms of Gros Colman, and it is mainly to his recommendation of it that it has been dispersed over the country. It has now fallen into the hands of skilful Grape-growers who know how to bring out its merits, and it will become one of the grandest of our late-ripening and long-keeping Grapes.

Gros Colman is the name by which it was introduced, and it is under that name that it first appeared in M. A. Leroy's catalogue of 1860. It seems to have travelled westward from the East, for in the catalogue of Jacquemet-Bonnefont of

Annonay for 1858 it is mentioned by the name of Gros Colmar. In that of De Bavay in 1852 it is called Gros Colman, and this is the earliest record I can find of it in nurserymen's lists. It can be traced through Germany, where it has been for many years known as Gros Kölner, and it is of this name that the French Gros Colman and Gros Colmar are corruptions. Through Germany we trace it eastward through Austria and Hungary, where it is grown under many names, among others those of Karzhina, Zherri, Seleniack, Vronck, Kapzhina, and Velka Spina. Our figure represents merely the shoulder of the bunch.—H.]

SEASONABLE NOTES ON FORCING FLOWERS.

PREPARATION must now be made for forcing in earnest. Gardenias are always acceptable. Plants in a forward state

Fig. 64.—Gros Colman Grape—Berries natural size.

plunged in bottom heat of 75° , and with a brisk moist top heat of about 70° , they will soon swell the buds, but the plants at a great distance from the glass. *G. florida*, *intermedia*, and *Fortunei* are most suitable. *Tabernaemontana coronaria flore pleno* well set with buds is amenable to similar treatment, and its flowers are as fine as Gardenias. *Eucharis* that has been kept in a cool house, now plunged in bottom heat of 85° and top heat of 70° to 75° , will throw up the flower scapes readily, few flowers being more acceptable at the new year. *Clerodendron Balfourianum*, which has been resting for some time, should be brought into the stove or house with a temperature of 65° to 70° , and having a good soaking of water and a top-

dressing given, but not disturbing the roots much—merely removing the loose surface soil, replacing with fresh loam and well-decayed manure, will with good attention give a quantity of flowers in a few weeks; indeed no plant affords so much bloom as this, or is more accommodating. *Jasminum Sambac flore-pleno* will keep on flowering all the winter with little excitement.

Lily of the Valley should be introduced to heat at intervals, so as to secure a succession of flowers, which are always welcome. It is mere waste of room to pot clumps without any regard to the size of the crowns, as is often the case with homegrown plants, which afford many more leaves than flowers. Imported clumps, for the most part, have crowns with flowers in them. In using home-grown plants only the strong-blooming crowns should be chosen, potting them about an inch apart in pots or pans, the points of the crowns being level with the surface. They should be plunged in ashes to the rim, and be covered a few inches in thickness with cocoa refuse or other light material. If placed in frames so that heavy rains and snow can be kept from them it will be an advantage.

Where Hyacinths are wanted early a few of the earliest potted should now be placed in heat, assigning them a position near the glass, and not warmer than 50° to 55°. Narcissus also, and Tulips, with Scillas should also be introduced, and if they are taken from the plunging material they must not have the growth subjected all at once to full light, but have flower pots inverted over them, which, admitting light by the holes in the bottom, will cause the growth gradually to become green, when the pots should be removed altogether.

Pot Lilacs well furnished with bloom buds, and place the plants or bushes in a house with a temperature of 55° to 65°, and in due time they will flower splendidly and be much prized. The white Lilac is most preferable, requiring no blanching as is sometimes practised with the purple. If the purple-flowered be wanted white it must be grown in a dark house or have light excluded, but its flowers are very desirable grown in light from their lilac colour and sweetness.

Azaleas Belgian, pontica, and mollis var., *Rhododendrons* of the early-flowering hybrids, such as *Nobleanum*, *Early Gem*, *Caucasicum album ciliatum*, *coriaceum*, *limbatum*, *altaclarensis*, *Brilliant*, *Wellsianum*, *Rosamond*, *Marian*, *Mars*, are all valuable for forcing, not omitting *fragrans*, *Govenianum*, and *odoratum*, which with *ciliatum* are sweet-scented; *Kalmia latifolia*, *K. myrtifolia*, and *Daphne cneorum* major should all be potted and placed at once under glass, for the roots suffer if the soil becomes frozen. They do fairly well plunged in ashes over the pots in a sheltered situation, from whence they may be draughted to the forcing house as required, but a house or pit is preferable, having means of excluding frost. Other shrubs for forcing are *Deutzia gracilis* and *D. crenata flore-pleno*, *Prunus sinensis alba flore-pleno*, *Viburnum Opulus* and *V. plicatum*. All these should be placed under cover without delay, or have the pots plunged in ashes.

In lifting plants from the open ground a fair amount of root must be preserved to each, for, however desirable it may be to limit the size of the pots, the reduction of the ball or roots may be carried too far.

Spiræa (Hoteia) japonica and *S. palmata*, and *Dielytra spectabilis* should also be potted; they, like the shrubs, being best in a cool house just safe from frost. A commencement may now be made with forcing all the preceding, introducing the requisite number of plants at intervals of about three weeks, so as to keep up a succession of bloom. Where there are vineries and Peach houses at work there will be no difficulty in forcing the shrubs and plants named, but separate structures are very much better for this work.

Andromeda floribunda, Christmas Roses, and *Laurustinus* will be sufficiently accelerated by being placed in an ordinary greenhouse. Violets in pots should be placed near the glass and be ventilated freely, not allowing the plants to suffer by want of water, giving them weak liquid manure occasionally. Those in frames can hardly have too much air whenever the weather is mild; removing every yellow or decayed leaf as they appear is a ready mode of avoiding damping-off, along with ventilation when the external air is above 35°.—A CONSERVATORY FOREMAN.

MANETTI VERSUS BRIAR STOCKS.

As I have always been an advocate for the Manetti as a stock, I venture to say a few words with regard to "W. H. J.'s"

remarks on page 405. When anyone can afford to dig deep trenches, put in clay or marl at the bottom, then add fresh soil with cow dung and pig manure, there is no reason to doubt that the coarser and stronger roots of the seedling Briar will succeed, and the more delicate and smaller fibres of the Manetti roots would most probably perish. Cuttings from the Briar, just like seedling Briars, form much coarser roots and answer well in strong soil, and also in highly manured unctuous soils; but the question which we still have to bear in mind is, Which is the most generally useful stock in the ordinary garden soil, neither heavy clay or blowaway sand, or stony brash? Briar cuttings may be budded either on the stem of the cutting as the Manetti, or the shoots as on the ordinary hedgerow stock, just according to the state of the cutting or the bark. If Roses on Manetti stocks are too highly fed there is an inclination to produce succulent shoots without much bloom in the autumn; but properly pruned Roses on the Manetti in the summer, on ground that suits them, rarely fail to produce good blooms. I cannot agree, therefore, with "W. C. A." that Manetti are falling into disrepute, although I quite agree with "D." that in many soils more attention is being devoted both to Briar cuttings and seedling Briars.

I have had a Manetti shoot sent me by the Editors from Ireland, which has more the appearance of a sucker than anything I have yet seen, but I refrain from making any definite remarks till I receive, as I have been promised, a plant of Charles Lefebvre with a decided Manetti sucker on it. Mr. Hinton has somewhat shaken me in my definite assertion that all so-called suckers of the Manetti are merely developed wood buds on the cuttings which had not been removed prior to budding, or afterwards when planted.

I quite agree with "D." of Deal that with a few exceptions this has not been a favourable year for Roses. It is a good sign to note how English-raised Roses are gradually coming to the fore, and we may well hope that this state of things will continue.—C. P. PEACH.

GRAPES AND PEACHES IN ONE HOUSE.

OFTEN many people with a limited number of glass houses like to grow as many things in them as possible, and those with only one or two houses, or say one vinery, would no doubt be pleased to grow both Vines and Peaches in the same structure. This plan is generally considered impractical—an inference drawn probably from the dual cultivation not having been properly tried in suitable structures. As we have found that nothing answers better than growing Grapes and Peaches in the same house, that house and its arrangement may perhaps be usefully described. Than this vinery and Peach house combined we do not possess a more profitable structure. The house is a lean-to, 60 feet in length and 16 in width. The back wall is 16 feet high, and the front of the house, glazed to the ground, is 5 feet high. Three Peach trees are planted in the inside border 4 feet from the front lights, and are trained to a trellis that is arched to the path near the back wall, and from thence is continued vertically to the roof. The whole of this trellis is covered with the Peach trees. From the point where the trellis reaches the roof—6 feet from the top—the roof is unoccupied, and thus light is afforded for Peaches on the back wall. These are three standards. The lower part of the wall, not covered with the branches of the Peach trees, is occupied by a *Maréchal Niel* Rose—a wonderful plant that has made 500 feet of growth in twenty months and yields hundreds of grand blooms. It is a surprise to all who see it, and affords evidence that this superb Rose thrives well in a somewhat shaded position.

Now to the Vines. There are twelve of them planted 5 feet apart. They are planted along the front of the house with their roots outside. The rods are denuded of foliage until they reach the roof for the purpose of admitting light to the Peach trees. The bearing portions of the Vines are trained up the roof until they reach the upright Peach trellis, the rods being 11 feet in length and are 3 feet above the Peaches; this distance and the ample front glass admit a sufficient diffusion of light for the trees.

The house is not artificially heated. At the present time it is freely ventilated night and day. From the beginning of March it is kept close unless the temperature rises very high, when air is admitted. During February the *Maréchal Niel* shows signs of forming flower buds. When the house is closed these soon swell, and in April the fine crop of blooms is secured. When February is mild the buds of the Peach trees

are generally swelling by the beginning of March, and they are soon in full flower after the house is kept close. The fruit forms early in April, and during July and August it is gathered. At the same time the Vines are not idle, as by May the bunches are formed, and the crop is generally quite ripe by the middle of September.

As a rule the six Peach trees bear over thirty dozen fruit, the twelve Vines twelve bunches each. The Peaches are Noblesse, Prince of Wales, Royal George, and a Victoria Nectarine; the Vines, Black Hamburg, Black Alicante, and Lady Downe's. The fruits of both Peaches and Vines are always exceedingly fine, as every person remarks who sees them. No particular treatment is carried out. When the weather is hot outside the ventilators are opened freely, otherwise they are kept close; in cold weather the inside is kept rather dry. All the Peach tree roots are inside. They are very freely watered throughout the year. Much attention is paid to keep every leaf clean. The side shoots of the Vines are kept closely pinched to one leaf beyond the bunch, so that there are spaces between them to admit light to the Peach trees. We always think we obtain a double crop out of this house, and the cost of producing the whole is trifling.

About November, when the house is damp with no means of drying it, we cut all the bunches of Grapes with a piece of the stem attached to each for inserting into the mouth of a wine bottle filled with charcoal and water, and when placed in a dry room the Grapes keep good for the greater part of the winter.—A KITCHEN GARDENER.

NOTES AND GLEANINGS.

"D., Deal," writes, in reference to the NATIONAL ROSE SOCIETY—"In my notes in last week's Journal I made an error in dates. That of the Manchester Show should be July 12th, not 14th; and as some misapprehension has arisen from my saying that the dates were fixed, I did not mean that they were *definitely* fixed, as at the meeting of the General Committee where they were arranged it was determined that they should be submitted to the annual meeting. I take this opportunity of saying that Dr. Hogg has kindly consented to take the vice chair at the annual dinner, and that a goodly gathering of rosarians may be expected."

— ON November 22nd the opening address for the season of 1878 and 1879 was delivered to the members of the DARLINGTON GARDENERS' INSTITUTE by Mr. E. Pease, the President. A peculiarly interesting portion of the address was that part of it relating to the flora of the Pyrenees on which were found many of those sub-Alpine plants which enrich the hills and pastures of Upper Teesdale. It was noted, however, that the *Gentiana verna*, *Primula farinosa*, which up the Tees bloom at a height of 500 feet above the sea, there flowered at an elevation of from 3000 to 4000 feet. On the Pyrenees were found *Anemone ranunculoides*, *Primula integrifolia*, *Corydalis solida*, *Dentaria digitata*, *Cardamine pyrenaica*, *Pinguicula grandiflora*, *Erythronium Dens-canis*, *Meconopsis cambrica*, *Isopyrum thalictroides*, *Hepatica triloba*, *Gentiana acaulis*, *Erinus alpinus*, *Saxifraga oppositifolia*; in pastures below the Pyrenees, *Anemone coronaria*, and *Centaurea Cyanus*; near Arcachon, *Bartsia lanceolata*, *Erythraea pulchella*, *Anagallis tenella*; near Baritz, *Lithospermum prostratum*, *Narcissus Bulbocodium*; also a parasite on the Poplar, *Clandestina rectifolia*. Mr. Pease said he had been struck with the beauty of a field covered entirely with the flowers of the scarlet *Anemone*. The party gathered a few, and the owner asked for a gift, as he could not get rid of the *Anemone*, and no profitable crop would grow near it. An added interest was given to this part of the address by the exhibition of water-colour drawings of all the flowers named, beautifully painted from nature by a lady.

— ONE of the most useful ORCHARD HOUSES we have recently seen is in the gardens of Lord Ormathwaite at Warfield Park. The structure is a lean-to, 140 feet long and nearly 18 feet wide—light, lofty, and well ventilated. It is in divisions, and is mainly devoted to the cultivation of Peaches, Nectarines, and Plums. The mode of training adopted, although not new, is commendable. Instead of a continuous trellis of the usual kind arranged from the front of the house to the back pathway, a series of upright trellises are formed at 7 or 8 feet intervals from the ground to the glass crosswise of the border of the house. By this arrangement an equal or greater extent of trellis is provided than by the mode usually

adopted, and, as is obvious, the trees on the back wall are not shaded, and the wall is thus furnished to the base. The border between the upright cross trellises is occupied by low bush trees in pots—the trees, being started in early vineries, are brought into the orchard house to mature their crops; by this means a long and abundant supply of fruit is provided. All the trees are in admirable bearing condition, and reflect much credit on Mr. Brodie, Lord Ormathwaite's competent gardener.

— IN the above-mentioned park, which is richly wooded, a permanent mode of indicating the AGE of many TREES is apparent. At a short distance from the stems dressed stones more than a foot square are firmly inserted, and on these the names of the planters of the trees and dates are deeply cut. There substantial tablets tell that Wellingtonias 35 feet high, and in robust health and splendidly furnished, were planted in 1860. The Spanish Chestnut trees in the park are grand specimens, and here and there are venerable Oaks that command attention. On the lawn an *Araucaria cones* freely, and near it *Yucca gloriosa* has become a tree, the stems being nearly a foot in diameter: as bearing eight fine spikes of flowers this venerable specimen had a fine effect. In the flower garden a large bed of the old Monthly China Rose is still covered with flowers: indeed we were informed that the bed contained flowers almost all the year round; but fine trees constitute the chief feature of the old place, and they are evidently cherished by Lord Ormathwaite and his family.

— THE great increase both in the number and the quality of the entries in the POTATO CLASSES at BIRMINGHAM was very marked. Mr. Peter McKinlay, of Woodbine House, Beckenham, carried off the first honours in this department. In class 16 he was awarded the first prize of £5, and also Messrs. Suttons' cup, value five guineas, for the best twelve distinct varieties. Those shown by Mr. McKinlay were Snowflake, Trophy, Extra Early Vermont, Early King, Suttons' Woodstock Kidney, Grampian, Emperor, Schoolmaster, Rector of Woodstock, Blanchard, Triumph, and Breadfruit. One dish in the exhibit—Suttons' Woodstock Kidney, won the extra prize of a silver medal for the best dish of Potatoes in the show. In class 17—for eight varieties, four of them to be American—there was a severe competition between Mr. James Pink of Faversham and Messrs. G. & J. Perry; but the first prize, a silver cup, value five guineas, given by Messrs. James Carter & Co., was awarded to the former for a very well-grown collection, comprising Snowflake, Carter's Breadfruit, Excelsior, Early Rose, Brownell's Beauty, Schoolmaster, Improved Magnum Bonum, and Model.

— MR. BOYES informs us of a striking case of DICHROISM that has occurred on a Rose in his garden. Last summer he had a shoot of the White Bath Rose on which were two white flowers, two pink, and two half white and half pink. On another flower stalk were two flowers half white and half pink, one pink one, and one pure white. We have known the same Rose produce a solitary pink flower occasionally, but we do not remember hearing of a plant so sportive as the one above mentioned.

— MESSRS. RICHARDSON & BEST, Paternoster Row, London, are issuing a new edition of a child's presentation book entitled "FACTS ABOUT FLOWERS." Mixed with the facts is much wholesome sentiment; and instruction is given on collateral subjects as they occur throughout the volume. The book is written in the form of a dialogue between father and child, and the ideas are appropriately clothed in simple language easy of being understood by very young children. The volume contains a coloured frontispiece forming a border round the name of the child to whom the book is presented. It is a pretty gift book, suitable for being placed in the hands of any child in whose mind it is desired to incite a love for flowers.

— ONE of the most useful of ornamental-foliaged plants for hall and corridor decoration is *ASPIDISTRA LURIDA VARIEGATA*. Its bright green persistent foliage beautifully striped with creamy white resists the effects of cold, dust, and a dry atmosphere better than does that of almost any other variegated plant. Although the plant is nearly hardy, it is highly worthy of greenhouse treatment, and of a little extra heat and care when producing fresh foliage. It is grown extensively and well on the Continent both in a large and small state, and is found to continue healthy in rooms and corridors for months together.

— WE find in the *Gardener's Magazine* the results of a trial of 116 varieties of POTATOES grown at Stoke Newington by Mr. Shirley Hibberd. The majority of the sorts produced poor or much diseased crops, which were nearly worthless:

indeed the list on the whole is a melancholy one. A few of the varieties produced what is termed "paying crops," and the following are selected as the best varieties arranged as nearly as possible (all points considered) in the order of relative merit. 1, Covent Garden Perfection; 2, Magnum Bonum; 3, Clarke's Cranemoor (late white); 4, Sextus; 5, McKinlay's Pride; 6, Suttons' King; 7, Snowflake; 8, Peach-blow; 9, Schoolmaster; 10, Woodstock Kidney; 11, Clarke's Late Prolific; 12, Early Ashleaf; 13, Early Hammersmith; 14, Brownell's Seedling; 15, Early Oxford; 16, Suttons' Queen; 17, Model; 18, Scotch Regent; 19, King of the Earlies; 20, Redskin Flourball; 21, Paterson's Victoria; 22, Early Rose; 23, Champion of England.

A ROSE GARDEN.

"A BLAZE of colour for a few days, a feast of Roses, and then all was over till the autumn." So said "WYLD SAVAGE" a

short time ago when telling us of the display of Roses in his garden this year. Extend the days to weeks if you will, but at best it may fairly be asked, Are Rose gardens really ornamental except during the brief period of flowering? I trow not. Many a Rose garden have I seen, but hardly any—certainly not more than one or two, that at all approached my ideal of what such a garden should be. It may be useful to describe two extreme examples; the first, a simple design consisting of a central circular bed some 10 feet in diameter surrounded by four of those oblongs and four circles, with which we are now so familiar, with a similar outer ring of longer oblongs and circles, forming altogether a group of seventeen small beds laid out on turf, of which there was a wide margin outside with an irregular semicircle of Rhododendrons, shutting in the group in a cosy nook in a somewhat secluded spot upon which one came unexpectedly round a curve of a shrubbery walk from among tree and shrub groups. The effect was charming—not from any novelty of design, for

Scale 20 feet to the inch.

evergreen climbers.

everybody is familiar with that who has read Loudon's "Encyclopædia of Gardening"—but from the well-chosen situation in such admirable harmony with the soft outlines of the beds, and the relief and warmth which the turf and shrubs imparted. The second is a rectangular space quite a dozen times the size of the first, laid out in a series of large square beds and long borders with intersecting paths, a trellis of poles around the outside for climbing Roses, and the whole shut in by lofty trees. Everything about it was stiff, formal, and uncompromising. In point of fact it was a mere large plot devoted solely to the production of large flowers for exhibition.

Now there can be no reason why all Rose gardens should not be made as attractive as our first example, and this can only be effected by mingling Rose beds with others containing shrubs, or placing them near groups of shrubs and trees, which thus act as a foil to the flowers and lend warmth to the scene

throughout the year. That Rose beds should contain nothing but Roses all will agree who are aware what a gross feeder the Rose is, and how requisite high culture and abundant supplies of manure are to keep it in vigorous health. Long and somewhat narrow beds or small circles are preferable, because they facilitate that close inspection of all the flowers which is so desirable, and which ladies are debarred from when they are planted in large deep masses.

Figs. 65 and 66 will serve to illustrate my teaching, and may prove useful to others as well as "A SUBSCRIBER," who "wants the plan of a Rose garden 30 yards square walled on three sides, the walls are to be covered with Ivy, a gravel walk and viney on the other side;" our correspondent also wishing it to be laid out on grass, which wish I have ignored, for to render so large a space attractive without paths would be to exclude most people from walking about it except in very dry weather

Both plans are drawn to a scale of 20 feet to an inch, and the spaces A A in both are retained for Vine borders, but if not required for that they may be turfed over and dotted with a few shrubs, or just one or two specimens.—EDWARD LUCKHURST.

FLOWER BEDS IN WINTER.

SUMMER and also autumn flowers are now over, and fallen leaves have for the most part been removed from lawns and flower beds. Especially where evergreens do not predominate gardens have now a comparatively blank and desolate appearance. There is, however, no need to have empty cheerless beds during the dreary season. A combination of dwarf bright shrubs and spring flowers will add greatly to the cheerfulness of any garden in winter. Shrubs with bright variegated foliage that I have found valuable for the purpose indicated are Gold and Silver Hollies, Golden Yew, *Aucuba japonica maculata*, *A. japonica*

limbata, *Osmanthus ilicifolius aureus*, and var. *argenteo-variegatus*, *Eurya latifolia variegata*, Gold and Silver *Euonymuses*, *Vinca elegantissima*, and Gold and Silver Tree Ives; these with *Cryptomeria elegans*, *Thuja aurea*, *Cupressus Lawsoniana nana glauca*, admit of very effective beds being formed for winter display. Golden Thyme, *Stachys lanata*, *Pyrethrum* Golden Feather, *Ajuga reptans rubra*, are useful for lines and groundwork, with *Erica carnea* in tufts, to which may be added for edgings *Sedums corsicum*, *glaucum*, and *lividum*, *Sempervivums calcareum* and *montanum*, *Saxifraga granulata* and *hirta*, and the Blue Grass (*Festuca glauca*), all of which are very effective. In flowering plants I employ *Aubrietias*, *Arabises*, *Alyssums*, *Daisies*, *Forget-me-nots*, *Primroses*, *Gen-tians*, *Hepaticas*, *Iberises*, *Pansies*, and *Violas*, with such bulbs as *Snowdrops*, *Scillas*, *Anemones*, *Hyacinths*, *Tulips*, &c.; also plants raised from seed, as *Wallflowers*, *Silenes*, *Limnanthes*, *Nemophila*, *Collinsia verna*, *Saponarias*, &c., which in combi-

nation with the foliage plants and miniature shrubs render the beds fresh and attractive through the winter and spring. Where Beet and variegated Kale are not objected to as partaking too much of the Cabbage garden, they afford a richness and delicacy of colouring that is unattainable by any other plant.

This subject has been previously alluded to. I refer to it now because the beds are now cleared, and there is yet time to plant, fine weather permitting, everything mentioned above. Until now work has been so pressing in many, if not most gardens, in clearing away decaying crops and leaves, that time has not been afforded for planting the beds.—A. G.

THE LIVERPOOL CHRYSANTHEMUM SHOW.

I HAVE taken in the *Journal of Horticulture* for a long time, and have been accustomed to rely on the information given; and shall be glad, therefore, if in your next number you will recon-

cile the account of the Liverpool Chrysanthemum Show given at page 405 with what appears in the *Gardeners' Chronicle*, page 696. In such competition I trust Wimbledon will always be "nowhere." Who were the Judges?—HENRY W. PEEK, *Wimbledon House, S.W.*

Both accounts are correct. The following explanatory letter sent by our Liverpool correspondent was not received in time for publication last week:—

"The first prize was originally awarded by the Judges (be it said to their shame!) to Mr. F. Roberts, Messrs. Tunnington, Peerse, and Elliott, following in the order named. Mr. Ollerhead subsequently entered a protest against the first award; and on the blooms being examined a disgraceful system of pinning and gumming two and three blooms together was exposed. Whereupon the Secretary said, 'Roberts shall be disqualified in everything, and that places Tunnington first, Peerse second, and Elliott third.' I cannot see how any good judge could award a prize to Roberts' stand. Mr. Tunnington's were grand blooms, and were honestly shown. Indeed he and Mr. Elliott offered their stands to be examined, in order to give Roberts no straws to cling to as well as to give

public satisfaction. The swindle was detected and first mentioned by Mr. Tunnington and Mr. Burgess, who would no doubt have entered a formal protest had not Mr. Ollerhead moved so promptly, properly, and effectively in the matter. The Judges for cut blooms were Mr. Dale of the Temple Gardens, London, and Mr. Wilson, Hampton Gardens, Hereford."

Another correspondent to whom we wrote relative to the discrepancy referred to by Sir Henry W. Peek, has replied as follows:—

"The report in the *Journal of Horticulture* is correct. Roberts was originally awarded the first prize, but was afterwards disqualified for the reasons correctly recorded in the *Gardeners' Chronicle* by Mr. Ollerhead. There is, however, one error in the letter referred to. Mr. Roberts was not first last year, but Mr. Tunnington; and Mr. Meerse was first in 1876 in the principal class for cut blooms. If the judging had been good Mr. Tunnington ought to have been placed first this year in the first instance, his stand being generally considered the finest that has been seen in Liverpool. Every gardening paper that reported the Show and all the local papers published the awards the same as appeared in the *Journal*."

[In reference to the disgraceful practice referred to we perfectly agree with Sir Henry Peek, that so long as a suspicion of dishonest exhibiting is allowed to exist at any show that all honest exhibitors will best consult their self respect by refraining from competing where prizes are won at the sacrifice of honour.—EDS.]

GARDEN FENCING.

I HAVE been putting up fencing for a gentleman round his kitchen garden, and as the fence has given the greatest satisfaction it might suit the requirements of Mr. Laxton. The material is corrugated galvanised sheeting, the kind used for roofing, sold here very cheaply by the manufacturers in short lengths termed "wasters." It was put up in the following manner: The posts (railway sleepers) are 6 feet long, 2 feet in the ground, 8 feet apart, the sheeting being 8 feet long and 2 wide, one sheet laid above the other, punched through and nailed to the posts with 3-inch clamp nails. The above fence forms a very neat, unusually warm, clean, cheap, and impenetrable screen. When required it can be easily moved, and a man with the help of a boy can put up 50 yards a day, the whole being very strong.—GEORGE G. BIRMINGHAM.

NOTES ON VILLA AND SUBURBAN GARDENING.

OWING to the absence of severe frost Oaks and some other trees have retained their foliage for a longer period than usual, and much extra work has been occasioned thereby in keeping gardens neat, and the final sweeping-up and the digging-in of the borders have had to be prolonged accordingly. We generally have all borders dug over by the last week in November; this season, from the above causes, the work cannot be completed nearly so soon. As soon as possible let all grass walks, &c., have a thorough sweeping and rolling; then proceed to regulate and dig the borders, carefully burying the leaves as the work proceeds. To those whose time has been occupied in lifting and transplanting trees, shrubs, or fruit bushes the open weather in the south has been most favourable, and it will be well if this work be hastened on, as the ground is liable to be frost-bound at any time now.

PITS AND FRAMES.—The occupants of these now require unremitting attention. Air must be given on all favourable opportunities, and decayed leaves must be removed promptly, for if left they will cause the tops of the plants to decay. Particularly is this the case with bedding Geraniums. It will not be safe to keep Cinerarias in cold frames any longer, although while the weather remains open they grow freely and are more free from green fly in frames than in heated structures, but the plants are very liable to injury by frost. Calceolarias are harder than Cinerarias, and sufficient covering may be placed on the pits to render the plants safe. If green fly should infest either of these plants or show or fancy Pelargoniums fumigate them with tobacco or tobacco paper, for if the insects are permitted to increase they will speedily ruin the plants. Tebb's fumigator is very useful for amateurs. The tobacco paper is ignited by lighting a few pieces of paper; the door of the fumigator regulates draught as required.

Pelargoniums that were cut back after blooming, and shaken out and potted, will now require another shift into the pots they are intended to bloom in. Useful home-decorative plants may be grown in 6-inch pots. The plants thrive best in good loam enriched with about one-fifth of well-decayed manure and a good sprinkling of silver sand. Drain freely, pot firmly, and water sparingly during the dark days. The plants must be kept near the glass, and tying and pegging down the shoots must be resorted to for forming dwarf bushy specimens; further, pinch out the points of the shoots when from 4 to 5 inches long.

Introduce bulbs such as Hyacinths, Tulips, Crocuses, Narcissuses, &c., that have been plunged out of doors for some weeks into gentle warmth, to forward them to supply the place of the Chrysanthemums in the conservatory. Camellias, Ericas, hyemalis, Wilmoreana, and gracilis, and Epacris of sorts, are all welcome occupants of our conservatories after the Chrysanthemums have ceased blooming, as also are Lily of the Valley, Callas, Rhododendrons and other forced shrubs. Do all watering that is required in the early morning, so that the atmosphere may be dry before night.

Vines that ripened their Grapes late should, if possible, be encouraged to cast their foliage by applying fire heat during the day and admitting plenty of air during the whole time; and rods already denuded of their foliage should be pruned and cleaned ready for starting after they have had a season of rest. In pruning the laterals should be cut off close to the lowest eye that has had a leaf to support it during the summer. The leading canes, if the Vines have not reached the top of the house, should be shortened according to their strength. If strong, about 4 feet of growth may be left; if weak, 2 feet will be sufficient. Young Vines that have grown very weakly are best cut down to the base of the rafter, which will ensure a stronger growth next year. Remove any loose outer bark, and paint the Vines with a mixture of soft soap, tobacco water, and sulphur for the destruction and prevention of insects. It is also a very good plan to scrub the woodwork of the vinery and trellis at the same time with soft soap and warm water; this is work that can be conveniently done during wet weather.

In the kitchen-garden department Cauliflower and Cabbage plants must be dusted with soot and lime as required to prevent their being eaten off by slugs. A few roots of Rhubarb and Seakale may be taken up, the first being placed under the stage in an intermediate temperature, or in a box placed in heat. Seakale must have all light excluded, but where no indoor warmth can be had both Rhubarb and Seakale are easily forced by placing pots over the crowns and covering them with leaves or leaves and long manure, taking care that the fermenting material does not become too hot. Trial sticks inserted will indicate the heat: the sticks when withdrawn should be only just warm.

WORK FOR THE WEEK.

KITCHEN GARDEN.

THE rapid fall of the leaf will admit of operations being pushed forward with alacrity now that the weather continues open. Where the soil is strong manure is best applied now, very strong soils being improved by ashes, charred refuse, and burned clay, leaf soil and other decayed vegetable matter of a loose nature being desirable applications. Light sandy soils and those that are thin and gravelly are better with the manure applied in late winter or early spring prior to planting or sowing, as if applied at this season the fertilising properties are considerably reduced by being carried downwards by rains below the action of the roots, the soil being of poor retentive power. Such soils are permanently improved by a dressing of clay or marl, spreading it on the surface in small lumps so as to be acted upon by frost, and when fallen dig or fork in. Twenty to sixty cartloads may be applied per acre according to the nature of the soil. Neatness being of some importance in private gardens it is requisite to clean the borders adjacent, so that leaves, &c., are not left to be blown over newly-dug ground. Complete the taking-up of late root crops, such as Parsnips and Jerusalem Artichokes, which are improved in quality by being stored in sand in a cool place; this prevents the unpleasant work of having to take up the roots in wet or frosty weather. A portion of Horseradish may also be taken up, trimming and sorting all fit for use, storing the roots in soil or in damp sand. Similar remarks apply to Rampions and winter Radishes—Black Spanish, China Rose, and Californian Mammoth; if kept dry the roots will shrivel. Root houses cannot be kept too cool, merely excluding frost. Potatoes intended for planting in the ensuing season should, so soon as space is available suitable for the purpose, be placed in single layers, kept cool, frost merely being excluded so as to prevent early growth, it being important that the first growths or sprouts be retained; this more particularly applies to the early kinds; but it is always desirable to preserve the first growths, and not to have them more than half to three-quarters of an inch long at planting time. Refuse from the garden or elsewhere should not be neglected, considering that it provides a valuable supply of rich fertilising matter at a trifling cost. With ordinary attention in turning the heap occasionally and adding some quicklime and a little salt, the former for the hastening of decomposition, both being destructive of garden pests, such refuse is rendered very useful. When thoroughly reduced the compost forms a capital dressing for root crops. It is also one of the best dressings for lawns and fruit trees generally, having a sixth part of lime added, which should now be done in the quick state, and left until February or early March, when the heap will be in fine condition for use.

FRUIT HOUSES.

Pines.—Well-ventilated pits or small houses properly heated are

the most suitable for young stock, which at this season often suffer irreparable injury from being kept too close and warm, the plants becoming drawn and weakly. At night 60° should not be exceeded, but a mean between that and 55° at night, which with 65° in the daytime, will keep all young stock gently moving, admitting a little air at the top of the house at 65°, leaving it on all day, but not to lower the temperature below that point, and when the sun raises the temperature to 75° a free circulation of air should be allowed. The bottom heat should be kept steady at 80°, avoiding anything approaching to a damp atmosphere; moderate humidity will suffice. Apply water only when the plants become dry, and then give weak liquid manure. Keep the plants well up to the glass, and allow them plenty of room. Suckers ready for starting now it is advisable to keep until March, and if there is likely to be a scarcity of suckers then any recently potted may be retained in 5-inch pots, affording them a light position in a moist pit, with a slight bottom heat and a temperature of 55° at night, keeping them rather dry at the roots. In the fruiting department 65° will be ample at night, 5° lower in the morning in cold weather, 70° to 75° by day. Take every opportunity of collecting leaves whilst dry, and whenever a favourable opportunity offers push forward whatever may be necessary in the renewing or augmenting the fermenting beds.

Vines.—The house or houses for affording ripe Grapes before the end of May must be started without delay, nothing contributing more to a good break than a bed of leaves and stable litter placed on the floor of the house, turning over a portion of it daily so as to afford a supply of ammonia to the atmosphere. The outside border should also have the needful protection from cold rains and snow, two-thirds of leaves to one of stable litter affording a less violent but more lasting heat than dung. Provided the outside borders were covered with bracken, straw, or litter in early autumn so as to throw off the wet, the temperature will be considerably warmer than that of borders exposed, and in their case covering with hot litter may be dispensed with, but a covering of warm litter is preferable, especially to those borders exclusively external. The inside borders should be brought into a thorough state of moisture by applying water, or in the case of weak Vines liquid manure at 90°. Start with a night temperature of 50° in severe weather, 55° in mild weather, and 65° by day, except the weather be severe, when 55° will suffice, not exceeding those figures until the growth commences. Maintain a moist atmosphere by syringing occasionally, but excessive moisture excites the emission of aerial roots from the rods. Depress the rods to the horizontal line or below, to ensure the regular breaking of the eyes. In the earliest house started last month the temperature will need to be increased to 60° at night in mild weather, 55° in severe weather after the eyes break, and gradually increasing so to have it 60° at night when the Vines are in leaf, 65° by day in severe weather, and 70° to 75° in mild weather with moderate ventilation. The evaporation troughs need not as yet be charged with liquid manure provided there is fermenting material within the house; but if not, 1 lb. of guano to twenty gallons of water is suitable for the purpose, and also watering Vines in pots, the water being applied at the temperature of the house. Tie up the Vines in position as soon as growth has fairly commenced, and before the shoots are so long as to be liable to be damaged in the process. Sprinkle the house two or three times a day in clear weather, avoiding a very muggy atmosphere on the one hand, and a dry one on the other. Disbudding should not be practised until the fruit shows in the joint of the shoots. Midseason houses are pruned and at rest; if not, complete the work and the cleaning of the houses, &c., without delay. Excepting the very late kinds, as Lady Downe's, Alicante, &c., which should not be cut until the new year, any houses that have the Grapes partially cut may have the remainder removed with a good portion of wood attached, and that inserted in bottles of water with a piece of charcoal in each will keep admirably in a dry room from which frost is excluded. This will liberate the houses for painting or pruning, there being nothing equal to a long and complete rest for Vines, which early pruning effects more than anything else.

Peaches and Nectarines.—When the buds in the house closed last month have commenced swelling maintain a temperature of 40° to 45° at night and 50° to 55° by day, admitting air moderately at the latter figure, allowing the temperature to rise to 65° from sun heat, syringing the trees and every available surface morning and afternoon until the bloom buds are showing colour, after which the syringing of the trees should be discontinued, but the sprinklings of the house, walls, and paths continued as before. There must be no attempt at a close atmosphere, but allow a chink of air at the top of the house to lessen the condensing of moisture by the glass. The inside border will require to be watered with water slightly warmer than the mean of the atmosphere, maintaining the soil in a thoroughly moist state. Borders entirely inside require careful watering, making sure that every part of the soil is properly moistened. Outside borders will be benefited by lights or shutters in addition to a covering of bracken or litter for throwing off heavy rains and snow. The house for affording ripe fruit at the end of May or early in June should be closed about this time, but no fire heat should be applied except to

exclude frost, and for an hour or two in the early part of the day if the weather be severe, not, however, exceeding 50° by fire heat, syringing the trees and every available surface morning and afternoon. A ridge of thoroughly sweetened leaves and stable manure placed in the house after the border is thoroughly moistened will afford a genial atmosphere superior to that obtained from hot-water pipes, admitting air whenever the weather permits of doing so, Peaches delighting in a well-sweetened atmosphere. Complete without delay the pruning of Peaches and Nectarines under glass, thoroughly cleaning the glass and woodwork, whitewashing the walls, and dressing the trees for the destruction of insects, and top-dressing the borders, keeping the house as cool as possible but ventilating abundantly in mild weather.

Figs.—The earliest house, or that with the trees in internal borders, should now be closed with a view to having ripe Figs in May; but where the earliest Figs are had from trees in pots, the starting of the trees planted in borders may be deferred until the new year so as to afford a succession, yet if the trees planted out be now started they will afford a closer succession to those now being forced in pots. Water in a tepid state should be applied to the roots at frequent intervals until the soil is thoroughly moistened, introducing thoroughly sweetened leaves and stable manure in ridge form into the house to produce a moist genial atmosphere and induce gentle excitement as well as to economise fire heat. Commence with a temperature of 50° at night, 55° by day, and 65° from sun heat, syringing the trees and every available surface in the morning, and early in the afternoon unless the weather be dull and cold, when the morning syringing only should be practised. Admit air moderately whenever the weather is mild, closing the house with sun heat at 65°, or if it exceed that with full ventilation close the ventilators when the sun heat begins to decline. The earliest forced trees in pots must not be over-excited by too much bottom heat, but as the fermenting material settles more should be added and pressed firm, being very careful not to allow the heat about the pots to exceed 65°. When the buds are swelling freely the temperature may be increased to 55° at night, 60° by day by artificial means, admitting a little air at that and allowing an advance to 70° or 75° by sun with corresponding ventilation, closing at 65°. Sprinkle the trees and house morning and afternoon, or in the morning only if the weather be dull. Young trees intended for forcing in pots another season should be shaken out and repotted, starting them into growth shortly or at once, so that they may make the necessary growth and complete it early so as to have time to rest before being forced for fruiting. Brown Turkey and White Marseilles are good for early work, Negro Largo is also excellent.

Cherry House.—The pruning of the trees in this structure must now be attended to. Full-grown trees regularly stopped during growth will require very little pruning. Any that have grown considerably should be cut back to an inch of the base of the current year's growth, and the worn-out or decayed spurs should be removed. The terminal shoots in the case of trees not full-sized must not be shortened unless the extremity of the trellis is reached, and the central shoot or shoots of young trees will require to be cut back as may be necessary to originate shoots for filling up the space regularly. The fan mode of training is the most suitable, and is more particularly applicable to the Cherry, as it admits of replacing any branch that may fall a prey to gumming. Plum trees succeed in the Cherry house either planted out or in pots and tubs, and like Cherries require to have the roots restricted; established trees in pots and from the orchard house, or in the case of trained trees from a wall, being selected, they should be pruned, seeking to maintain uniformity of appearance. All last year's growths will require shortening; superfluous shoots remove entirely, avoiding having the shoots of these or Cherries too thickly placed. A few dishes of Plums early in the season are a welcome addition to the dessert. Early kinds should be chosen, as July Green Gage, De Montfort, Denniston's Superb, Royale Hâtive, and Green Gage. Plums, like Cherries, like good loam, with about a sixth of road scrapings and a tenth of old mortar rubbish thoroughly incorporated. The house should have a thorough cleaning, the trees being washed with soapy water (8 ozs. to a gallon is not too strong), and then dressed with a composition formed of half a pound of soft soap to half a gallon of water, half a gallon of tobacco juice with four parts of flowers of sulphur, and one part each of slaked lime and soot added so as to bring it to the consistency of thin paint, applying with a brush, being careful not to dislocate the buds. The house must be thoroughly ventilated until the time arrives for starting the trees.

Strawberries in Pots.—The plants introduced or to be introduced shortly to the vinery, Peach, or other forcing houses should have the drainage scrutinised, making sure that it is free, and the loose surface soil removed, and a top-dressing given of dried cow dung or horse droppings rubbed fine with the hands, adding about a twelfth part of bone dust or buffalo horn manure well incorporated, then watering it with a rose watering pot so as to bring into a moist state, for if put on dry it washes off in watering the plants. The pots may then be placed in position after removing any decayed leaves, making sure that there is no deficiency of

water at the roots, for the old leaves will not show signs of a deficiency of water until the soil is very much too dry for healthy root-action, therefore rap the pots; a practised hand will readily detect by the sound which plants are needing water. Black Prince is still the best very early Strawberry, followed by Vicomtesse Hericart de Thury, La Grosse Sucrée, and Sir Harry, one of the very best of forcing Strawberries, and an admirable autumn fruiter, but the fruit does not bear carriage well.

PLANT HOUSES.

Stove.—Plants at rest of a deciduous character—such as Allamandas, Clerodendrons, Bougainvillea glabra, &c.—will only require but little water occasionally to keep the wood from shrivelling and in the case of evergreens enough water only should be given to keep the foliage from becoming limp. Such plants as flower at this season will require to have water according to their requirements, making the distinction, however, between a plant at rest and one in or advancing to the flowering stage. Centropogons, Aphelandras, Eranthemums, Plumbagos, Thyrsacanthus, Begonias, Centradenias, Euphorbia jacquiniæflora, Pentas, Poinsettias, Epiphyllums, Conocliniums, Dalechampsias, Mussandias, Burcheillas, Toxicophleas, &c., must have water as required, assisting plants in small pots with liquid manure. Those with other winter-flowering plants require to have a moderately moist atmosphere and light position, the flowers being poor comparatively when grown away from the light, and do not last near so long as those near to the glass. A gentle syringing in the morning and early afternoon will still be necessary in bright weather, being content with damping the floors, &c., in dull weather, maintaining a temperature of 60° at night, 5° less in the morning in severe weather, 65° by day from fire heat, or 5° less when the external air is cold and dull, with an advance from sun heat of 10° to 15° with moderate ventilation. Ixoras should have a temperature at least 5° more all round. Lose no opportunity of freeing plants of mealy bug and scale. The former is readily destroyed by paraffin, a wineglassful to four gallons of water thoroughly mixed by squirting alternately into the can and over the plants. It is also good against scale, yet not nearly so efficacious as against bug. Both the brown and white scale are destroyed by a wineglassful of spirits of turpentine and 8 ozs. of soft soap to half a gallon of water, applying with a brush, syringing well a few hours afterwards with pure water, the plants being laid on their sides. Thrips often thrive apace at this season; subdue them and aphids by fumigation. Caladiums should not be kept dust-dry; but with the pots placed upon a moist bottom and occasionally sprinkled the corms will keep sound. As a decorative plant none rivals *C. argyrites*, which grown in brisk moist heat is as useful at this season as any; *C. Belleyei* is also nearly as good. Both may be kept going with little or no rest. Both *Gloxinias* and *Achimenes* winter safely in a temperature of 45°, the soil being kept rather dry, but dust-dryness is pernicious. *Eucodonia*s should be kept in the stove moderately dry, *Tydas* and *Genaras* of the *Zebrina* and *Exoniensis* sections being kept moist and afforded plenty of light.

TO CORRESPONDENTS.

. All correspondences should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense. Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

WHITE GRAPE IN GREENHOUSE (*Birchdale*).—We are unable to recognise the name of your Grape by the description you have given, and shall be glad to receive a few berries by post. Your soil and position appear well suited for Grape-growing, and we are glad to hear of your success.

IRIS-LEAVED PLANT (*J. M. C., Brighton*).—It is quite impossible for us to determine the name of your "curious plant," either by your description or the rough sketch enclosed. We think you have done quite right in placing a handlight over the young plant to protect it from the inclemency of the winter. We advise you to prop the handlight up or otherwise admit air to the plant during all favourable weather.

GLOBE ARTICHOKE (*Mid Surrey*).—Although the plants are hardy you cannot err by placing some littery refuse round their stems, for we find that protected plants often produce heads earlier than do plants that have been left exposed.

WINTER ONIONS (*J. B. D.*).—We should not transplant them now, but thin them out slightly if overcrowded, further thinning them in early spring, and transplanting those then removed.

DIVIDING MAIDEN-HAIR FERN (*H. H.*).—Let the plant remain as it is until the spring and divide it about March, or when new fronds are commencing to push freely, and then you will have more heat to promote the speedy re-establishment of the plants.

PRUNING VINES (*A Young Gardener*).—As the leaves are all yellow and are falling freely, you need not hesitate pruning the Vines at once; indeed the sooner they are pruned the better if you start them in January.

TRAINING ESPALIER APPLE TREES (*F. J.*).—Your principal aim should be to have the lower branches in advance of those above them, shortening

the extremities accordingly, and pinching out the tips in summer of any shoots that are growing too luxuriantly. If any of the lower branches do not grow freely they should be trained in an oblique instead of a horizontal position for a year or two. It is advisable to cut off the unripe tips of the branches, or blossom buds may form there, and then the after-growth would not be free. A length of from 18 to 24 inches is not too great if the wood is mature. Take out the leader entirely when you have obtained the requisite number of branches. Your light soil cannot well be made too firm, but running the hoe carefully through the surface to the depth of an inch will not do any harm, and you need not change your present practice.

PRIMULAS NOT FLOWERING FREELY (*Ellen*).—Your greenhouse is fully too cold for them. They require a warmer temperature than *Calceolarias* and *Cinerarias*. The latter will keep healthy if just safe from frost, but *Primulas* require a temperature of 45° to 50° when showing their flower stems.

PLANTS FOR WINDOW SILLS (*Suburban*).—No plants are more ornamental for outside window sills during the winter than dwarf *Euonymuses*, *Retinosporas*, and variegated *Ivies*, with such berry-bearing shrubs as *Pernettyas*, *Skimmias*, and *Aucubas*.

GROS COLMAN GRAPE (*E. S., Berks*).—It is a noble Grape and good in quality when grown in a high temperature and ripened early. See notes on this Grape in another column.

FISH POND (*Gregory*).—Puddling with clay the bottom and sides is necessary in almost all instances. When the excavation is formed, or partially so, the bottom puddle near the outer edge is formed, and upon this is raised the upright or side puddle; and as this proceeds the ordinary clay or earth is raised at the same time, by which means the upright puddle is retained in its place; and ultimately the sides, being formed in a sloping direction, admit of being covered with gravel or sand, and may be walked upon, or stakes may be driven to a considerable depth without reaching the puddle or in any way injuring it. This can never be the case if the puddle, as is sometimes done, be laid upon the sloping side of the pond. The sides may slope rapidly, or the reverse. If the slope be considerable, sand or gravel, to give a clean appearance, will be more likely to be retained upon the facing; plants can be more easily fixed and cultivated; gold fish, also, find in these shallow gravelly parts under the leaves of the plants suitable places to deposit their spawn, and without this they are seldom found to breed.

BRIAR STOCKS (*W. Tipton, E. Thody, and Others*).—You can adopt no better course than to advertise them, as good stocks are scarce in many localities.

NEW ROSES (*F. R. M. R., Kilkenny*).—The following varieties of recent introduction are worthy of being added to your collection:—*Boisidien*, cherry red; *Dr. Hogg*, claret; *Lord Beaconsfield*, rosy crimson; *Dean of Windsor*, vermilion; *Emily Laxton*, cherry rose; *Hero of Waltham*, purplish crimson; *John Bright*, vivid crimson; *Marchioness of Exeter*, rich rose; *Marquis of Salisbury*, reddish crimson; *May Quennell*, magenta carmine; *Mrs. Laxton*, rosy crimson; *Penelope Mayo*, carmine; *Richard Laxton*, reddish crimson; *Rose Morn*, rosy salmon; *Waltham Cross*, deep rose; *Comtesse de Serenye*, satiny rose; *Duchesse de Vallombrosa*, satiny rose; *Duke of Connaught*, velvety crimson; *Magna Charta*, rosy crimson; *Queen of Bedders*, crimson; *Marquise Adèle de Murinais*, rose; *Marie Louise Pernet*, bright rose; *Mons. Gabriel Tournier*, deep rose; *Madame Sophie Froppet*, bright rose. *Teas*—*Comtesse Riza du Park*, coppery rose; *Souvenir de Georges Sand*, salmon rose; and *Mrs. Opie*, rosy salmon. The fine new Hybrid Perpetual Rose *Comtesse of Rosbery*, reddish salmon, and *Duchess of Bedford*, velvety crimson (*W. Paul & Son*); and *Dr. Sewell*, maroon crimson; and *Harrison Weir*, crimson scarlet (*Turner*), will be obtainable early in 1879. They are varieties of undoubted merit.

SEEDS FOR CYPRUS (*Rev. M. H.*).—Any that are suitable for the climate of England are worth trying in the island of Cyprus.

MICE EATING BULBS (*R. T.*).—Wet the bulbs and then roll them in red lead.

PLANTING SHALLOTS (*Amateur*).—Plant the offsets at once if the soil lies dry. If planted in beds, let them be 3½ feet wide, and 3 or 4 inches higher than the alleys, and the surface of the bed a little arched. Set out the rows 9 inches apart from row to row; spread a mixture of soot and charred refuse along the line about to be planted, and then plant the offsets singly with the hand upon the surface of the bed 6 inches apart in the rows just pressing each bulb down firm in the soil. See occasionally that they are not cast out of their places by worms or other vermin.

PRUNING VINES (*L. S., Liverpool*).—Pruning on the spur system consists in carrying up one leading shoot to the back of the house, establishing thereon what are termed spurs, or what might, perhaps, be more properly termed snags, from the front to the back, as nearly as possible, at measured distances, and as far as may be placed alternately up the stem. About one to every foot is sufficient; perhaps better than more. These spurs are first developed as side shoots; and in order to insure their due and full development they are produced during about three seasons. There are those who will run a cane up to the back of the house, and fruit it the whole length the next year; but this is not substantial practice. A good cane nearly the length of the roof, and about three-quarters of an inch diameter, may be pruned to one-third the after length the first year, another third the second, and the remainder the third year. By this plan, supposing the after 15 feet long, there will be about five large bunches the first year, ten the second, and fifteen or more the third; and this will be found to tax the powers of the Vine heavily, perhaps too much. By this mode every side shoot will be strongly developed, and consequently a selection may be readily made. The subsequent pruning simply consists in cutting each of these back annually to the last eye at the base of the young side shoot, although some leave another eye.

PLANTING HYACINTHS (*Lady B.*).—Plant the bulbs immediately the soil is dry enough to be worked freely. To prevent treading upon the bed lay upon it a narrow piece of board long enough to reach across it, or have the board strong enough to bear the planter's weight, and raise it up at each end high enough to clear the bed; plant them with a dibber thick enough to make a hole as wide as the largest Hyacinth is in diameter, and the end that is thrust into the soil should be cut across, and a mark made just as far from the bottom as the bulbs should be covered with soil; the proper depth is 3 inches from the top of the bulb. Each Hyacinth should have at least 5 inches square of surface to grow in, but 6 inches would not be too much space for the leaves to expand, especially if the same bulbs are to be planted

again the following season. As the planting proceeds have some light compost ready, sifted through a coarse sieve, and fill up the holes with it. When so covered the bulbs are sure to be at the right depth; then rake the bed very lightly.

ADDRESS (B. Roberts).—We are unable to furnish you with any address such as you require. If you have a boy whom you wish to be a gardener, your first step should be to obtain employment for him in a garden in your district. A small garden is as good as a large one for the first year or two.

CUCUMBERS UNHEALTHY (Constant Subscriber).—As you appear to have given careful and good attention to the plants we can only account for the rusting of the foliage by the possible overheating of the pipes. A deficiency of piping is the source of many failures of plants and crops in houses where a high temperature has to be maintained, and is also expensive by the great consumption of fuel that is inevitable under such circumstances. Even if the pipes in your case have not been overheated, we should gradually reduce the temperature of the house about 5°—i.e., having 65° instead of 70° as the minimum.

POMPON CHRYSANTHEMUMS (X. X. X.).—Out of so many good varieties it is not easy to select "the best yellow, best white, best rose or lilac, and best red for affording a large supply of cut flowers," but the following are good: yellow—St. Michael, or Golden Circle; white—Mlle. Marthe; rose or lilac—Lilac Cedo Nulli, or Durand; red—Bob, or Maroon Model.

CYCLAMENS NOT FLOWERING (J. Walsh).—The temperature—40° to 45°—is too low. For the plants to grow and flower freely they require a temperature of not less than 50°, and preferably 55°. One of the most healthy and fine collections we have seen this year is in Messrs. Sutton & Sons' nursery at Reading. The plants are kept near the glass in a temperature seldom below 60°, and are copiously watered. They are splendid, some of them being 18 inches in diameter, and laden with fine flowers, and yet the plants were only raised from seed sown in September of last year.

ZONAL PELARGONIUMS (J. D. Oron).—Vesuvius and its white and salmon sports are all excellent for winter flowering. You will find cultural notes in another column.

CUCUMBERS UNHEALTHY (Gardener).—The soil is much too light and too fine to promote strong healthy growth. Obtain some very rough, rich, turfy soil, warm it, remove carefully as much of the present soil as you can without injuring the roots, and you will have stronger roots, better growth, and no maggots and insects such as infest the present compost.

RENOVATION OF EXHAUSTED VINES (T. Byrne).—Cut out the old rods, shorten the young canes half way, or rather in proportion to strength. Take only a moderate crop of fruit next year, and if you have not already done so, lose no time in applying a heavy surfacing of rich farmyard manure to the border. Allow plenty of freedom to the young growth, and see that it is not overcrowded and is kept clean and healthy.

SURFACE-DRESSING A VINE BORDER (T. C.).—If the border is of an average depth of 2 feet, the excellent compost you describe would do most good if added along the front of the border by way of making it wider, placing upon the surface a heavy dressing of rich manure, and repeat the dressing annually. You are quite right to encourage a free strong growth in the vines, and should regard pinching as a necessary evil, only to be put in practice to keep the growth within bounds so as to avoid overcrowding.

CAMELLIA BUDS DROPPING (J. G. S.).—Plants looking exceedingly healthy and with the pots thoroughly drained may shed the flower buds from one or two causes, and these are repeated saturation of the soil by heavy rain if the plants are placed out of doors in summer causing many of the roots to die, and a want of water after the setting of the buds. Turn a few plants carefully out of the pots, and if you find plenty of healthy roots depend upon it the centres of the balls are or have been so dry that an ordinary watering would do no good. Take, therefore, each plant and immerse it in a tub of water, and if air bubbles rise abundantly and for some time, then no doubt drought in the centre of the ball is the source of the mischief, and each plant should remain in the water till the bubbles cease rising.

LARGE DESSERT GOOSEBERRIES (A. B. C.).—Red: Companion and Speedwell. White: King of Trumps and Patience. Green: Green Overall and Lofty. Yellow: Leader and Goldfinder.

GLADIOLUSES IN POTS (Idem).—For soil mix equal quantities of loam and old manure, and about half the quantity of leaf soil, and the same of silver sand. Employ 7-inch pots drained thoroughly. Divide the bulbs into three lots, potting the first at Christmas, the second in February, and the third in March, in order to secure a succession of bloom. Plunge the pots in ashes in a frame, and when the growth appears place them on a shelf in a light airy position in a greenhouse. Attend carefully to watering, and give liquid manure regularly when growth is active. Remove them to a cold pit in April, giving air freely on all warm days.

NAMES OF PLANTS (A. C.).—2, *Lithospermum fruticosum*; 3, *Ruscus Hypoglossum*; 4, *Andromeda salicifolia*; 5, *Toumouchea shrivelled* for identification; 6, *Escallonia montevidense*. (W. Jones).—1, *Euonymus japonicus aureo-variegatus*; 2, *E. latifolius variegatus*; 3, *Phillyrea latifolia*; 4 is an *Ilex*, and 5 an *Acanthus*, but we cannot determine the species from the scraps sent. (*Chrysanthemum*).—It is *Beauté du Nord*, described in Mr. Turner's catalogue in 1858 as a large reflexed flower, and before a separate section was formed for Japanese varieties. Well-grown flowers would now be exhibited in the Japanese class, but medium blooms could not be excluded from a stand of reflexed flowers. It is of the same form as *Triomphe du Nord*, but darker in colour.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

SHEEP FOR THE HOME FARM.

(Continued from page 415.)

THE merits of the Southdown sheep must be next considered, for they may not only be kept for the purpose of furnishing mutton of good quality for use at the mansion, but for profit in

connection with the stock of the home farm as well. In all moderate-sized farms they will have to be purchased instead of being reared, as mutton of full age (that is from four-year-old sheep) is most esteemed by the epicure, and sheep are usually killed and sold at two years old. Particular management is necessary to produce mutton of full age, otherwise the joints will be found to be rather too heavy for ordinary family consumption. Now to hold sheep on from lambs for three years will necessitate their being kept in the poorest of the park or pastures, so as to keep them healthy yet in only stock condition. They will not need anything beyond the produce of the grass land in summer and hay in the winter. When kept in this way they will grow slowly and be of moderate weight. The flock may be drawn from say a score at a time and put on to good food on the arable land, or in winter to be fed in the house or shed, as under cover they are found to thrive faster and make more meat for the food consumed than when fed in the open fields, eating one-fifth less food and making one-third more mutton during the period of feeding.

House feeding need only be resorted to in the event of the sheep being required for use within a given time. The Southdowns being fast feeders will generally become sufficiently fat after twelve weeks' feeding for home consumption. When, however, they are required to be fed and fattened in the summer months they should be taken out of the park pasture and placed upon the arable land, receiving green food, the earliest being rye, to be folded off or cut up and put in cages if it is a full crop, and at the same time having mangolds cut and mixed with about a quarter of a pound of linseed cake, and the same quantity of bean or barley meal, for each sheep. After the rye is all used then the trifolium will be ready to be treated and managed the same as the rye, mangolds and meal being continued. The clover or vetches will then be ready, after vetches the second crop of clover, and thus continue the same mode of feeding until the root crops are ready, all of which should be cut and mixed with cake and meal, early turnips first, or cabbages, whichever may be fit at the earliest period. The Thousand-headed cabbages come in early when early planted. After these succeed white Belgian carrots, and then Swedes, which will last until the rye is again ready, the mangold crop being reserved for the feeding of cattle, and used in conjunction with green fodder crops as before stated. This will complete the rotation of feeding and fattening for the year, except that we have omitted to state hay will be necessary whilst the animals are being fed upon roots in the winter months, the quantity to be as much as they will eat without waste. We must not forget to have a lump of rock salt so placed that the animals can have access to it at all times. In order to keep up a constant supply of sheep fit to kill, it will be necessary to add ten sheep at a time to the fattening lot draughted from the stock or poor sheep, so that the number of fattening sheep should not be less than twenty or any other number which the requirements of the establishment may necessitate to insure a regular supply. In this way any breed of sheep of light weights adapted to the neighbourhood in which the home farm may be situated can be fed, so as to supply the highest quality of mutton.

Another mode by which old mutton can be obtained is by purchase of full-mouthed ewes of the Southdown breed. These of the smallest size can be obtained in stock condition at the Lewes summer fair, as well as some other fairs in Sussex, where these ewes are sold as off-going stock from the chalk hills of the county. They are usually purchased to breed from by the farmers on the vale farms, and as these ewes are poor when they are purchased they may be put into the park or pastures, and gradually improved in condition, without cake or corn until Michaelmas. They may then be put to root-feeding, and be treated as before stated for fattening the same as the wether sheep, and they will furnish mutton of full flavour at either four or five years of age as required, the difference only being that the meat will be rather drier and without the quality in some other respects of wether mutton of full age.

We have now arrived at that point when the second heading of our subject must be considered—viz., the feeding of sheep for profit. As we have types and breeds of sheep adapted for all districts of the kingdom we must endeavour to keep only those sorts which have been tried and proved by the most experienced farmers of the districts where the home farm may be situated. This is really one of the leading points to be considered.

The management of Southdowns having been explained we will next take the Hampshire downs as obtained from the fairs in Hants and Wilts. Wether sheep may be bought in either large or small numbers at all the summer fairs in these counties; but it is questionable whether wether lambs kept in the same way will not be more profitable feeding for the butchers than wether sheep, because we have not only the benefit of feeding them up to fatness but at the same time we get their increased growth with also the increase of wool, so that lambs purchased at about six or eight months old of this Hampshire stock and kept on have been known to make an increased value per head of from 20s. to 30s. for four or five months' feeding. These young sheep taken into any dry sandy or gravelly land or hazel loam soil will, under ordinary circumstances of good food and good shepherding, be sure to yield a good return. As soon as they arrive at the home farm they should be put upon the best grass upon the farm, and particularly the young clover seeds, if they are purchased before the early turnips are fit to feed; and if early turnips are fit when they arrive it is a good plan for the sheep to run the clovers at daytime and then go into a folding of turnips in the evening for the night, and there to receive their artificial food in conjunction and in admixture with the cut turnips in troughs, all the artificial food being given in the meal state, whether it consists of decorticated cotton cake, bean, or barley meal, all three of these kinds of food being better than linseed cake for young growing sheep. They may at first receive about half a pound per day each, but afterwards, about six weeks before the appointed time for selling, they may receive with advantage 1 lb. per day each. They will not require hay until they have finished feeding on grass and are entirely confined to the close fold on turnips. Many farmers argue that common turnips are so soft and easily eaten by the sheep that they do not answer or pay for being cut and put in troughs; but we contend that young stock just before or about the time they are shelling their teeth will do much better with cut turnips in troughs, because they eat their food in little time, have more time to take rest, and they make more profit in consequence, and it is but little trouble to clean or cut common turnips.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—Upon some farms there will still be wheat-sowing going on, because where the practice is to sow wheat after turnips fed off, or mangold cleared away, there may still be land to be seeded. Now the season is so far advanced every opportunity must be taken and seed sown of a sort adapted for late sowing. We know nothing more hardy and more suitable for late sowing than the Red Nursery and Golden Drop, and it is no bad plan to mix them, both being good millers' grain, and ripen about the same time. The Nursery is a white chaff, and Golden Drop red chaff. A bushel and a half of Golden Drop and one bushel of Nursery per acre is a suitable mixture, because the Nursery is rather a smaller grain, and the plant will tiller out more in the spring. At this time of year never plough without sowing the same day; we are then sure of a seed time, let the weather be ever so changeable. Having had a good spell of dry weather lately, land which has been under culture in the autumn has still been tilled with advantage during the past fortnight, except in those counties where a fall of snow has impeded the work. In all cases where the couch and weeds have been cleared off the land may now be ploughed, whether it is intended for potatoes in the spring or for mangolds, and if the weather continues dry enough fresh horse dung may be laid out and ploughed-in for either crop. We do not advocate applying manure in the spring for either crop, and if there is no season in autumn for manuring we prefer artificial fertilisers, particularly Peruvian guano, 4 cwt. of guano for potatoes and 3 cwt. for mangolds is sufficient to produce a full crop of either. Fallowing the land by deep ploughing may be continued for all root crops next season, but we should be careful to have the water furrows struck and made out upon all flat and retentive soil. The odd horse or horses will be engaged in carting away couch and weeds from the fallows before ploughing for the winter. The couch and weeds should be carried to a heap, there to decay, except there is any meadow land near; the rubbish may then be carted on to the grass land and spread, for we have often seen this improve pasture land as much as a dressing of farmyard dung. The odd horse will still be required in carting Swedes or turnips to the homestead for the cattle, also for horses and pigs. The feeding of the fatting oxen should now be carefully attended to, for where they have been recently put up to fatten they will now begin to make visible progress, but it must be borne in mind that feeding twice a day with 30 lbs. of roots at each feeding with

meal in admixture with the cut roots is sufficient. Some persons still persist in the old-fashioned plan of giving roots three or four times a day, but we find that twice feeding with roots and meal is best, because it gives time for the animals to lie down and ruminate, besides which they will eat between the intervals of root-feeding a good quantity of sweet straw of any sort, oat straw being the best; pea haulm too is good for them, but they do not like the haulm of blue peas. By this system of feeding the bullocks will be sure to digest their food and return to the manger with a good appetite, and it is in this way that they best assimilate the food given, 4 lbs. of cake and 2 lbs. of meal per day being sufficient—that is to say, if more is given they do not profit by it to the same extent, and much of the extra quantity will only go to swell the dung heap. We must again mention that hay should never be given to a bullock when otherwise liberally fed, as it is sure to injure its health, particularly after it becomes about half fat. Let the fatting cattle be kept in boxes if possible about 10 feet by 10 feet. We have never seen better boxes than those temporarily fitted up in a barn divided by three fir poles, and the manure accumulating under the cattle with earth at the bottom of the boxes for absorbing the urine. Where this is not done and cattle are tethered at the stall, the manure being cast out daily into the yard, much waste occurs, unless it is arranged that the dung from the cart-horse stables should be mixed with it daily, in which case it is a good plan to feed the breeding sows in a hovel adjoining, and let them run out all day upon the dung and have a few Swedes or other roots cast to them, for when they are properly confined to the dung heap they tread it down and improve the mass, being kept within bounds by some strong iron hurdles. We have adopted this plan often with great advantage.

BIRMINGHAM POULTRY SHOW.

THE thirtieth Birmingham Show opened on Tuesday. To those of us who have been used to see it through the latter dozen years of its existence in its present highly organised state, it is difficult to realise out of what it has grown. Miss Watts in her poultry book graphically tells the tale of the first Birmingham Show, how exhibitors brought just what birds seemed good to them, and how they were judged and exhibited in the baskets in which they came. That took place not thirty years ago. Mr. Baily was the Judge, and Mr. Baily was busied on Saturday last still making the awards in many of the most important classes. On the whole the progress of poultry during the interval must have been vast, yet that of particular breeds fitful. Some of those which during the first half of the Show's existence made the greatest improvement have since become stationary or have gone back, while others which were almost or quite unknown fifteen years ago are now in the height of perfection and popularity. We should be well content to have a few Cochins or Dorkings from the first Birmingham Show we saw some twelve or thirteen years ago, but the Brahmas and French fowls which won then would make but a sorry figure now.

The feature for which this Birmingham Show is remarkable is the first appearance of the electric light in Bingley Hall and in the poultry annex. Year by year the dissatisfaction at the fetid atmosphere of the poultry department, and more so of the Pigeon gallery, increased. Exhibitors grumbled, and a few were sufficiently merciful to their Pigeons or sufficiently public spirited not to enter, in the hopes of things being improved thereby. Certainly this year there must be many "abstentions" when one finds such popular varieties of Pigeons as Turbits represented altogether by twenty birds, and some of the Dragon classes with two or three entries, in which we were wont to see scores. However, many of the grumblers wait till next year and forget their grievances the day before the entries close. For the future we hope there will be no need for abstention or grumbling. While we write these lines we have not seen the full play of the magnetic light, but there is every reason to hope that the gas may be dispensed with, and that the atmosphere will be no worse than that of any ordinary public building. The poultry and Pigeon arrangements are in the main the same as of late years. The Bantams and some other small breeds have been removed from the gallery to Bingley Hall, and look all the better there. The Turkeys and Waterfowl are also, as of late years, in the Hall. The old wooden pens do not improve; their front bars in many cases are most dilapidated, and it will be a wonder if no birds escape. Many of the drinking vessels too cannot be hung up, the miserable birds upset them and live in pools of filth. We were promised on Saturday that some chaff should be put on the bare boards of the pens when the judging was over. This will improve their appearance and make the birds more comfortable.

Brahmas have for some years displaced the old English Dorking and now head the list. Dark cocks were a good class, but we think the Judge was mistaken in one or two cases. Cup went to a large, well-made hocked bird, but we think the third-prize was better in most points; he failed a little in marking on saddle, but was otherwise very good. Second we did not like, and should have put fourth in his place. Either of the very highly commended pens might have been fourth. The hens must have been

very difficult to judge, as the light was extremely bad, many of the pens being so dark the marking on the bird could hardly be distinguished. The cup hen was rather small and short of feather, but was good in colour, being much less brown than most of the others, and to that she probably owed her position; second was a hocked bird, good in shape and marking, but had a poor comb; third and fourth were both large birds, but rather brown. There were a good many pens highly commended, but the light was so bad we were unable to criticise them properly. Cockerels were a poor class, much inferior to the past few years. The cup bird was about the best, but by no means as good as Mr. Lingwood generally shows, being very narrow and slightly ticked on breast. Second was nearly as good but rather loose in comb. Third we liked very well. He was a good bird well shown, but would have been better if he had had more leg feather. Fourth was rather leggy and narrow; fifth a good cockerel with bad wing. The highly commended pens were none of them very good, and several hardly worthy of their position. The cup pullet was a hocked one, beautifully marked all over down to her foot feathering. Second looked like the cup pullet at the Palace. She only wants good leg feather to be perfect. Third went to a hocked bird, very heavily marked. Fourth and fifth were both well marked birds, but the former failed rather on cushion. The first and second old Light Brahma cocks were both very good birds, the former having the best head and comb, but otherwise they were nearly equal. The third we did not like; he was hocked, bad in comb, and too dark in hackle. We liked 136 (highly commended) or the fourth-prize bird better. 150 and 157 were both well-known winners, and might have been higher. The cup went to a cockerel which had little but his head and neck to recommend him; the same exhibitor's fourth-prize bird was as good if not better. Second we thought the best in the class. He was rather short of leg feather but was otherwise a good bird. Third had a good hackle, if anything rather too dark, and was rather white in tail. Fifth was good but in poor condition. In hens the cup pen was occupied by the Palace winner, looking very well; second was a good bird rather light in hackle, and we did not like her comb; fourth was a fine hen, rather short of feather. 203 and 205 both good birds out of condition; the latter was the champion of last year. The pullet cup also went to the winner at the Palace, and Mr. Birch is to be congratulated on possessing two such good birds. Second was rather creamy, and not so good in hackle as first; third was good in hackle but a little ticked on cushion. We rather preferred fourth. Fifth went to another heavily-marked bird. This class was not as good as usual, many birds showing a creamy tinge.

Dorkings are by no means what they once were at Birmingham. If we are not mistaken, at the first show we attended here there were sixty-seven Grey Dorking cocks. We should say that the falling-off is chiefly in the Dark variety, which we suspect has first been spoilt by crosses, and has in its modern leggy form become less popular, for the collection of Silver-Greys and Whites struck us as being as good as we have ever seen at Birmingham. The two winning Dark cocks (two prizes only where there used to be five!), were birds of the same type belonging to the same owner. These were both bony birds, long on the leg, and of medium colour. The second-prize bird was singularly devoid of breast. The birds which struck us as being most of what we consider Dorking form were 366 (Mrs. Troughton) and 369 (Cresswell), both unnoticed. The cup and extra three-guinea prize went to the first Dark cockerel. He certainly was immense, but long on leg with spurs badly put on, and with a drooping comb. Second was a fair bird, with fifth toes a little enlarged. Third a dark lumpy bird. Fourth a nice bird all round, a little flimsy in comb. Among the best of the class we thought Mr. Crewe's highly commended cockerel, which was capital in comb and shape, and three of Mr. White's cockerels. The cup for Dark hen or pullet went to a capital bird of Mr. Burnell's, good in colour, feet, and condition. Second, a good bird with a beautiful gloss on her plumage. Third, a well-shaped rose-combed hen. The first and third pullets belonged to one exhibitor, the owner of the cup cockerel. They certainly are by no means the type of Dorking we admire, being lanky and long-legged; however, if they fill out well they will make good hens. Second was in body a remarkable pullet, but was much spoilt by one of her feet being flat and narrow. The Silver-Grey classes were good all round, and far superior in shape to the Dark. The cup went to the Palace cup cock. His hackle has now grown, and he looked very well. He is, we believe, from a family which have for several generations won both the great cups—viz., at the Palace and Birmingham, and are remarkable for splendid combs. Second was a very silvery bird, but poor in comb. We liked Mr. Burnell's quite as well. The awards in cockerels struck us as peculiar. First is a good bird in shape, comb, and tail, but very yellow and with white lobes. Second is incomprehensible; a stilty bird with one very crooked leg. Third still worse, with a cup comb. Among the highly commended were two or three which we much preferred to the winners among Mr. Rutledge's and Mr. Cresswell's, the Crystal Palace cup cockerel. In hens Mr. Burnell took cup and first with his grand square old hen. Second was a large bird, and 478 (Denison) was good. Pullets were

generally an even lot, and mostly pale in breast. The first was large, not very smooth in colour. Second a pretty bird. Third very fully developed, we should think a daughter of the cup hen. Cuckoos were very few, three in each class. The first cock was too light; second much better in colour, but not good in feet. The first hen was very clear in marking, far ahead of the other two, which were cloudy. The cups have this year been out down. There were formerly two for White Dorkings, there is now but one, and this is competed for by the two classes of Cuckoos as well as by the four classes of Whites. It went to the Palace cup White cock, as large a White Dorking, we fancy, as we have ever seen. Second had a poor small comb and very yellow. We should certainly have put Mr. Boissier's highly commended bird, which was very white, in its place. The first cockerel did not at all please us either in form or colour, but he looked weighty. Second was a capital White bird which we thought easily first, though his comb was not perfect. The cockerel class was generally above the average. In hens a large long bird was first, a well-shaped square bird belonging to the same exhibitor. Second, Mr. Boissier's; and Mrs. Hayne's highly commended birds are both good. The only first-class pullet is the first. The Selling classes contain several very fair pens—bargains we do not call them, for, for our own part, we never think second-rate poultry cheap at any price.

Cochins.—Buffs were large classes, numbering over 150 entries. The first cock was short-legged, rich in colour and heavy in feather, with a dark tail; dark tails seem now to be the prevailing fashion. Second was not quite so short in the back as the first, of a good golden colour with a buff tail. Third, a curious contrast in shades of colour, being light in breast, and much darker in hackles and back, with a dark tail. There were some very good cockerels; the cup bird was splendid in form with short legs, short back, and excellent foot feathering. Second a fine and large bird, the general effect of the bird's plumage was curious from the difference in his shades of colour. Third, deficient in foot feather, otherwise a good bird. Fourth, much the same type as the cup-winner. Fifth, a nice bird all round, almost cinnamon in colour. Mr. Procter's famed winning hens need no description, the cup bird was not so bright in condition as she might be; the second has wonderful foot feathering; third again is a very good bird, not quite so good in cushion as Mr. Procter's birds; fourth, a smaller bird good in shape, but in so bad a light that we could not make out her colour. No less than forty-five pullets were entered. First is a small bird but perfect in shape and of bright even colour; second, a large bird of deep colour, a little twisted in hackle; third, a large-framed pullet, deficient in feather and a little marked in hackle; fourth, very dark and shapely; fifth, in a miserable light, apparently a large canary-coloured bird with a poor comb. There were many empty pens in the class for Partridge cocks. The cup went to a grand hocked bird of immense breadth with beautiful bloom. Second was certainly not his equal, not being well through the moult. Third was small but well shaped. The cockerels were under the gallery, and it was impossible to see their colour as well as that of the cocks. The winners we thought good, and the rest a poor lot. First was bright in colour, not very broad, and with stiff hocks. We preferred the second, but he had the advantage of being in an upper tier. He was fine in size. Third was short-legged and good in colour, but had not a good comb. They all belong to Captain Heaton, who seems to have returned to his old fancy. The cup hen was magnificent in the clearness of her pencilling, but was long in the leg and short in feather. Second was smaller and less distinct in pencilling, good in shape and feather. The third award surprised us. The hen was small, long in the leg, and poorly feathered. Several good grouse-like hens were left out. Pullets were a large class, and all three prizes again went to Captain Heaton. Their pencilling was stronger than their shape. In Whites Mr. Darby's redoubtable old cock was conqueror again. Second was a big and very broad bird, not the glittering white of the first. The first cockerel was very white and good all round. His legs might be a little shorter. Second was short on legs and heavily feathered, but yellow and rather long in back. The cup hen was admirable in shape and feather, but not very large. Second was decidedly small, but almost a dumpy in legs, white and fine in fluff. Mr. Darby's very highly commended bird was the whitest in the class. The first pullet was good, larger than many of the hens. Second will make a fine hen. We liked Mr. Tomlinson's highly commended bird much; and Mr. Darby's highly commended pullet, very young, now promises well. Black cocks were few. The first was a fine cock in fine condition and bloom. Second capital in form but spoilt by a drooping comb. We did not like the first cockerel, he certainly was large, but his back and tail made an ugly angle. Second was good all round; however, we prefer his owner's other bird. These classes partially faced the light, and partially looked the other way, which made it next to impossible to judge them properly. The first hen was very good in shape and gloss, she might with advantage have more leg feathering. Second was a fair bird, but we preferred Mr. Pritchard's. The second winning pullets will both be good hens; they are of the same type of bird, hocked and long in limb.

Malay cocks were fourteen in number. The cup bird was a fine Black Red, in good feather and splendid condition; was well deserving of his position. Second a fine heavy bird of the same colour, large, cruel-looking, good in head. Third was another very good Black Red, in fine plumage. 989 (Lowe) and 994 (Joint) were good, 998 (Strugnell) large and good, 1001 (Payne) good. In cockerels first was a very large long-legged bird, dark in colour and good in head. Second was a very dark bird, large and in good condition. Third, a shade lighter, very large and fine in limb. 1003 (Payne) was good and very dark in colour. In hens, first and cup went to a good light brown hen in nice condition. Second was a good bird, similar in style to first; only in at two guineas, and of course sold. Third was a rather darker bird, good in size. 1015 (Lowe), 1021 (Isaac) and 1022 (Lowe) good, darker birds. In pullets, first was a splendid bird, very large and good in colour; she must have run the first hen hard for the cup. Second was a good light brown bird. Third rather darker and smaller. 1034 (Lowe), large and good, but darker than the fashionable colour; 1036 (Burnell) good but small. Cockerels numbered twelve, hens ten, and pullets thirteen entries.

Creve cocks.—First-and-cup was a very large bird, rather wanting in crest, but good in comb. Second a very good crested and well combed bird, although good in size smaller than the winner. 1039 (Ward) large and good. In cockerels (eleven) first was a splendid fellow, large and good in comb, but not very perfect in crest. Second was a large bird, rather small in crest. 1043 (Ward), a good-headed fine bird; 1048 (Booth) and 1049 (Lloyd) good; 1051 (Wood) looked rather old. In hens (six), which were a small class and not very good, first was a very fine hen, splendid in crest and large in size. Second a fair hen with moderate crest. Pullets were eleven in number, and were better than the hens. First was excellent, good in crest and in fine plumage. Second much out of condition, very large and fine, and good in crest. The noticed birds all good.

Houdan cocks (seventeen) were more numerous than meritorious. First-and-cup was good in feet, dark in colour, and good in crest and comb, though perhaps too short in leg. Second was good in colour and size, moderate-sized comb and nice crest. 1074 (Lane) and 1081 (Naylor) good, also 1070 (Wood). In cockerels (seventeen) first was well marked and good in size, only moderate in comb, though good in crest, medium size. Second, a dark bird, was poor in comb, although fair in crest. Third, good in crest and comb, well marked and of fair size; good combs were very scarce in this class. In hens (thirteen) first was a splendid bird, fine in crest, good feet and large, rather light in colour. Second another very good hen, fine in crest, rather light in colour, with one malformed fifth toe. 1104 (Wood) a good hen, as was also 1114 (Herbert). In pullets (sixteen) first was a good-sized pullet, well marked and fair in crest. Second was pretty in crest, and good in size and marking. Third a good pullet, smaller than second, good in crest. 1126 (Mrs. Lane) was a very good pullet.

In *Spanish* cocks (six entries) first was good in quality of face, but defective in comb. Second good, but much out of condition; rather a poor class. In cockerels (seventeen) first-and-cup was a fine bird, splendid in face, with a very neat and rather small comb, fine drop, and in grand condition. Second a capital bird, apparently quite untrimmed. 1138 (Rodbard), 1139 (Walker), 1140 (Allsop), 1142 (Mulligan), 1146 (Jackson), 1148 (Dixon), 1149 (Powell), and 1150 (Le Sœur), were all really good birds. In hens (thirteen), first (sold) was a good hen in nice condition. Second was also a good hen, pretty in plumage, and good in face and comb. The noticed birds were all very good. In pullets (nine) first was a capital bird very good in face; this bird won the cup for hens or pullets. Second a well-grown pullet, good in head. 1170 (Mrs. Allsop), 1174 (Powell), and 1176 (Walker), all good. Many pens in the adult classes were empty.

We do not recollect that *Polish* ever before mustered so well at Birmingham, numbering in all ninety-eight pens. In Black cocks (five) first was a very fine showy bird, splendid in crest, which was, however, not quite up. Second very good in shape and even in front. If in condition we almost preferred him to first. 1324 (Unsworth) good. 1322 (Countess of Dartmouth) too forward in crest. 1326 (North) very good, untrimmed; perhaps the only one in the class so shown. In cockerels (nine) first was very good in crest and in fine condition. Second a very fine bird with a splendid crest. 1330 (Williams) and 1331 (North) good and untrimmed. 1333 (Lloyd) untrimmed, very dense crest, a very good bird. In hens (five) first a handsome, globular-crested hen, very good. Second another very good hen, very large in crest. 1340 (Shaw) a good hen. In pullets (seven) first was very compact in crest and very good, though with scarcely so large a crest as second. Second a beautiful bird, splendid in crest and very fine. 1341 (Lloyd) good crest, untrimmed. 1345 (Unsworth) good. 1344 (Silvester) one of the Palace disqualified birds, a good pullet. In Golden cocks (ten) first was the Palace winner, rich in colour, beautiful in marking, very good in crest, and fine in tail. Second was very bright in colour, beautiful breast, wing, and tail, and finely formed crest. 1348 (Shepherd) a large, heavy-crested bird, well marked, but light in colour. 1350 (Burrell) heavy in crest and a fine bird. 1351 (Silvester) very good in all points, but

scarcely heavy enough in crest. 1352 (Unsworth) a well-marked bird good in crest. 1354 (Webb) beautifully laced, large crest, but not good enough in front. 1355 (Partington) a good bird, too dark on the breast. 1356 (Rawnsley) rich in colour, but white in tail, fair crest. In cockerels (eight) first was a good fronted crest, dark on the breast and white in tail. Second fine in crest and well marked. 1358 good crest and well marked. 1363 (Rawnsley) a well marked bird with very good crest. 1364 (Scott) well-marked, but a little wild in crest. 1365 (Burrell) good, excepting a small comb. In hens (ten) first was splendid in crest and good in ground colour, but deformed. Second a well marked and good crested hen, rather dark. 1367 (Silvester) fine in crest, well marked, rather pale in ground. 1369 (Unsworth) nicely laced and fine crest. 1370 (Shepherd) very good crest. 1372 (Boothby) very good crest, good colour, and well marked. In pullets (ten) first was the Palace winner, a very beautiful pullet, fine in crest and good in all points. Second is another bird of the same stamp, but younger, and will be richer in colour. 1376 (Boothby) a nicely marked pullet. 1377 (Rawnsley) a very heavy crest, but too dark in marking. 1380 (Adkins) capital crest. In Silver cocks (eleven) the Palace cup-winner again took the cup here. He is a grand bird in splendid condition, with an enormous and well formed crest. Second enormous in crest and well marked. 1386 (Lady Dartmouth) most perfectly laced, and very nice in crest. 1389 (Silvester) enormous in crest, rather wild. 1390 (Adkins) thoroughly spangled, not laced on breast. 1391 (Lady Dartmouth) splendid crest and well marked. 1392 (Bloodworth) a good bird with spangled breast. 1396 (Bloodworth) good but rather dark. In cockerels (six) first was fine in crest and shape, good wing, and spangled breast. Second a nice bird with a little comb. In hens (eight) first we thought scarcely so good as second. First was grand in crest; in marking by no means equal to second, which was fine in crest and about perfect in lacing. 1403 (Lady Dartmouth) well laced, but not quite perfect in crest. 1404 (Adkins) very heavy in crest. 1408 (Bloodworth) very good. 1410 (Unsworth) very good, but not rich in front. In pullets first was rather dark in body but very fine in crest. Second looked rather old. She had a good deal of white in the crest—a very good bird, with very compact crest. 1414 (Adkins) a handsome pullet with fine and well laced crest. 1418 (Rawnsley) rather dark but very fine in crest.

Bantams.—The class for Laced Bantams was a very remarkable one, it is probably a long time since such a collection has been seen together. The cup went to the first pair in this class (Silvers), with very pure ground colour; the cock is a little gem with perfect hen tail. The hen a little larger in proportion, but a marvel in lacing; they were priced at £20, sold at the auction. Second was Golden; the hen very good. We thought the cock a little too large and not very even in ground colour. Lady Dartmouth's famous pair of Silvers were among the very highly commended pens. Mr. Elwell's highly commended pair were very good in ground colour, but the cock had too much tail. White Rose-combed seem looking up again; eight pairs appear. The first the best we have seen for some time, pure white with good lobes and combs. Second was good again, though rather large. The first Black Rose combs was small and good in colour, we did not at all like the cock's comb; second was very green and glossy, but again the cock had an objectionable comb.

Black Red Game Bantams.—First were very stylish young birds, nice colour and good heads. Second, good style, colour and head. Third rather larger, but good in Game points. Brown Reds.—First-and-cup a beautiful little pair, very gamey, capital heads. Cock good lemon colour and well laced. Pullet a trifle too coppery in hackle. Second good in colour, nice head and eye. Pullet rather large, nicely laced on breast. Duckwings.—First a very stylish pair, very good in colour. Second rather large, in other points good. In Piles only two pens, both good.

Any other variety was a most varied and interesting class. First are the well-known Cuckoos; second Japanese, white with dark tails. The very highly commended pair was dumpy spangled-booted. Mrs. Allsop showed a pair of the old-fashioned reddish-booted Bantams imported from China. There were also two pairs of black-booted and one of white-booted.

Sultans were a fair class. First cock very good; hen scarcely equal to second. Second nicely crested and well booted. Third a fair pair.

Andalusians.—First a very fine pair, cock in particularly fine trim. Second very good, nice heads and well laced. 1431 (Troughton) and 1432 (Miss Arnold) very good.

Langshans certainly looked as much like Black Cochins as ever. In adults only two pens were shown, both good birds. In young ones first were good, large, and lustrous. Second a good pair; third a large pair.

Leghorns.—In Brown first were a handsome pair, good legs, good combs, and in good condition, might be better in earlobe. Second a capital pair in good feather. The noticed birds good. In White first were a good pair but very soiled; second a nice pair. Leghorns do not seem to improve much.

Minorcas made nine entries. First were good in comb and fine in plumage, but not extra good in earlobe. Second a very nice pair, which we liked better than first.

In the Variety class first a good large pair of Plymouth Rocks in fine condition. Second the Buff Polish (Padone Chamois), which we thought might well have changed places with the winners. They were a handsome pair. Third Ermine Polish The cock looked ill, and both were diseased in feet. 1481 (Brooke) a pair of imported frizzled fowls—very singular.

Aylesbury Ducks were fine. First-prize pair weighed 22 lbs.; second 19 lbs. 12 ozs.; third 18 lbs. In Rouens first-prize pair weighed 23 lbs. 10 ozs.; second 22 lbs. 6 ozs.; third 21 lbs. 2 ozs. The Mandarins, Carolinas, Kasarkas, and other fancy Ducks, although not numerous, were very handsome and interesting classes.

Geese were splendid classes, particularly the Coloured. The first White Geese weighed 43 lbs. 10 ozs. Second, 42 lbs. 12 ozs. In Grey and Mottled, first, 49 lbs. Second, 46 lbs. 4 ozs. Third, 45 lbs. 2 ozs.

Turkey cock.—First, 37 lbs. 2 ozs. Second, 34 lbs. 12 ozs. Third, 33 lbs. 10 ozs. In young cocks.—First, 25 lbs. 10 ozs. Second, 25 lbs. 6 ozs. Third, 23 lbs. 12 ozs. In hens the weights were respectively 43 lbs., 45 lbs. 14 ozs., and 35 lbs.; and in young ditto, 38 lbs. 8 ozs., 33 lbs. 4 ozs., and 31 lbs. 12 ozs.

Notes on the remaining classes had not arrived on our going to press. The prize list will be found in our advertising columns.

JUDGES.—Poultry: Mr. J. Baily, Mount Street, Grosvenor Square, London; Mr. J. Dixon, North Park, Clayton, Bradford; Mr. E. Hewitt, Eden Cottage, Sparkbrook, Birmingham; Mr. W. R. Lane, New Street, Birmingham; Mr. J. H. Smith, Skelton, York; Mr. R. Teebay, Fulwood, Preston. Pigeons: Mr. T. J. Charlton, Blenheim Road, Manningham, Bradford; Mr. F. Esquilant, 4, Effra Road, Brixton, London; Mr. H. Child, 71, Long Street, Sparkbrook, Birmingham.

WEST KENT POULTRY SHOW.

THE first Show was held at the Public Hall, Bexley Heath, on Wednesday last and following day. The classes were well filled, and the Secretary, although new to the work, was quite equal to the occasion. On the Committee we notice the names of Rev. A. Kitchen and some other noted exhibitors, who have doubtless helped considerably to promote the success of the undertaking. The visitors on the first day were very few, in fact only a fancier could be induced to face the torrent of rain that fell without intermission throughout the day.

The winning Coloured *Dorkings* were a fine pen and well selected. *Cochins* eleven entries, all good; one pen (Wright) disqualified for a cut comb. *Brahmas*.—The Dairy Show cockerel was first, matched with a Mealy pencilled pullet; second a fine cock, hen not so good in colour. Lights not equal to Darks. *Spanish* only three entries; second prize withheld. *French* moderate. *Game* and *Hamburgh* classes well supported. *Leghorns* were capital classes. *Andalusians* well represented (a very dark pen), cock with a good comb winning. *Polands* we thought the best in the Show, Mr. Burrell winning with a magnificent pen. *Sultans* few, but good. *Bantam* (Game) classes poor. Any variety above the average. *Ducks* deserve special notice, notably the Pekins, Mr. Fowler was first and second with grand pens, but we thought Mr. Kitchen's pens equal to them; but they were out of condition, and not judiciously matched. The drake of pen 102 should have been shown with the Duck of 103, and *vice versa*.

The *Pigeon* classes were largely filled, but very inferior to the poultry in quality.

Four classes of *Rabbits* completed an excellent Show, which will doubtless assume in time much larger proportions.

Mr. Nichols was the Judge.

HINTS FOR YOUNG AMATEURS.—No. 6.

DRAGONS.

THE Dragon is a bird exactly suited to a young amateur whether he be young in years or in the fancy. I knew a school-boy who grew, as he considered, too big for Rabbits change them—such a number of them too—for his first pair of Pigeons, and they were Dragons—an advance as he thought, and that forthwith he would be admitted, as indeed he was, to be a pleased and proud visitor of Pigeon lofts. Fanciers, on the strength of the youthful one being now a fancier, would let him see their birds, he looking on awed while, he learning the names of the birds—learning to know them in the nest as well as when adult.

I have said that the Dragon is suited to a young amateur, but why? First, he is a bird that is perfectly independent; he is as easily managed as a common Pigeon. No nurses needed for Dragons, for they breed regularly and are model parents. They nurse tenderly the young of other Pigeons, therefore trouble in this way they give none. It is heart-rending for a young fancier to begin, say, with Shortfaces—Short-faced Tumblers—and, knowing nothing of their habits, to find pair after pair of young birds left by their heartless parents to starve, while they are cooing, and flirting, and billing utterly unconcerned. But nothing of this happens if Dragons be adopted as the pets; nine, ten, or even eleven pens of young birds are sure to be brought up safely

during a year. Then they, as the Scotch say, "can fend for themselves." Woe be to the Pigeon that ventures to attack, or disturb, or rob them of nest or food. They carry "a dagger of a bill," and that bill soon goes dagger-like straight into the interfeerer's skin, and he gladly gets away, having caught a Tartar with a vengeance. All the shorter-billed birds are beaten off without a chance of retaliation. Another thing as regards Dragons: They are safe birds to keep. See that remarkably fine but very helpless Pouter blowing away and strutting away after some little Miss Tumbler, who, I grieve to say, likes the big fellow's attention. This is going on on the ground in the sunshine, when lo! a strange cat—yellow-eyed, black, diabolical-looking—sees his opportunity, and remembers, smacking his wicked lips, how very nice that last Pigeon was. Soft, velvet footsteps that cause no noise steal behind that naughtily happy Pouter cock (far too engaged with the flirtation on hand to think of danger), when pounce comes the miniature tiger, the inflated crop in a moment is windless and the fine bird dead. While if the master rushes up he may be in time to rescue the body, but it is a "body," not a living bird. You might catch a weasel asleep or catch a Yorkshireman with both his eyes shut, but you can't catch a Dragon. He has, it is true, a wattle round his eyes, but not so protruding as to hinder his seeing behind him, as in the case of a high-class Carrier or Barb. A poor dear little Fantail if very high bred is a helpless bunch of feathers, and you may pick them up easily enough—only walk behind them—for they cannot see further than their tail, and being very small-brained little dears they appear, figuratively speaking, not to be able to see beyond their nose. If on a chimney they are sure to be blown down it; but no one, I fancy, ever had a Dragon blown down his chimney. Being among the more naturally bred fancy Pigeons Dragons are very healthy. Give them clean water and decent food—they are not particular what—and they will live and be prolific for years and years. I had an old Grizzle hen which came to me an aged bird, and her former master bought her as an aged bird, but year after year and almost month after month she had eggs and young.

To say that a true-bred Dragon is very perfect in symmetry is only stating what all know. They always remind me somehow of Game pullets—not cocks, and very game—very pugnacious (their only fault) are some of them. In truth their form is symmetry itself: narrow head and neck, broad shoulders, triangular breast, pointed wings, narrow tail; and this form mounted upon sinewy legs, long, but not so long as to look like stilts.

Next, their flight, or mode of flying. They are the very opposite flyers to Tumblers. Tumblers mount high and circle, Dragons go straight out and not very high; they go off, too, in a pack, as on a message.

I used to watch with much interest a near neighbour's Pigeons. He kept upwards of a hundred, and all at liberty. They were of many varieties, his great object being to get as many sorts as possible for the pleasure of seeing a variously-coloured and variously-made group of birds feed at his feet. Well, among this multitude were a number of Dragons. About three o'clock of a winter's afternoon, if in summer later, the Dragons as true as the clock would suddenly look at each other as much as to say "Now, boys, are you ready?" and away in a pack straight on end, as fanciers say, would they fly, going some miles in the same direction, not flying high like Tumblers but at safe distance from gun shot. Then they returned and went in to bed. They had been fed just before, so their motto was, "After supper fly a few miles." I used to watch their return, and think that never did their plumage look so tight or their form so elegant, so like Game hens, as when they alighted after their fly. I would next say a word on their homing powers. Until Antwerps came into fashion, some twenty years ago or more, Dragons were the only homing Pigeons used in England; and though I will not say they will fly from Rome to Belgium as Antwerps have done, yet what Englishman, as a rule, wants birds of such extraordinary powers? He has simply no use for such. The Dragon will do for all reasonable and likely distances well enough, and for business purposes, though not for cruel races. And then look at their beauty. The Antwerps have no more beauty than dovehouse Pigeons, while there is no handsomer Pigeon living than a Dragon, as I thought when walking past the long rows of them at the recent Crystal Palace Show.

This brings me naturally enough to speak of their colours. First stand the Blues, for this seems to show their form off best—the clear blue and black bars, and they are as a rule the best birds. But hard pressing the Blues come the Silvers, a kind of drab, but in the best bred birds very pearly and chaste. They are of two kinds: Silvers with brown bars, a variety of very great beauty, which I verily believe would have died out but for the perseverance of Mr. Bishop of Dorchester; and Silvers with black bars, or usually blackish bars, difficult to breed quite black, and therefore valued by fanciers; but in truth the brown bars harmonise most properly with the silver plumage. Artistically speaking the black bar is a mistake. Red and Yellow follow; fine colours, but not equal for Dragons to Blue and Silver. Form suffers from these colours. Also the blue or ash colour is very apt to

come in the tail of these birds; and this colour Mr. Darwin found easily returned to all Pigeons when cross-bred. White are simply exquisite, but instead of the fiery eye of the Dragoon comes the big, dark, and so called "bull eye" of the Fantail, which sadly spoils them. These white birds do admirably for nurses for Carriers, and any chance interbreeding would be at once detected. There are also two very old-fashioned colours—Grizzle, which has I am happy to say come up again, and Mottles, either grey-mottle, like an old-fashioned English Trumpeter Pigeon, or mottle as the mottle of a high-class Tumbler, just a few white feathers on the shoulders and back. Both these varieties are very pretty birds, and are some of the best shaped Dragons.

A last word about the name of this bird. Like some Scotch surnames it is one thing written another pronounced—that is, by the majority, particularly of the humbler fanciers. Yet from old Moore's day to this the bird is the Dragoon, yet it is still very often called the Dragon. I have seen them advertised as Dragons and Dragons, as if they were two kinds of birds; but Dragons they are—i.e., lighter Horsemen than the old fancy Pigeon of that name, and Dragons they ought to be called. The uneducated period of the fancy is over, the educated has begun. Show, then, fanciers that you know how to spell and how to pronounce. A vixen of a woman, violent-tempered, unkempt, untidy, a she-savage amongst the civilised, may be suitably called a Dragon, but not so should be called the graceful, symmetrical, elegant, clean, and spruce-looking Dragoon.—WILTSHIRE RECTOR.

VARIETIES.

GAME FOWLS AT THE CRYSTAL PALACE SHOW.—Our reporter asks us to correct two misprints in his report of the Game at the Palace. On page 399, in the ninth line from the top of the first column, the words "we noticed" should read "though unnoticed," and Mr. Harley's Duckwing pullet should have been described as "very" good. This correction was inadvertently omitted last week.

—THE American supply of hogs (pigs), in which this country is now immediately interested, this year promises to be large, and is now estimated at one million head more than last year, which was the largest yield in the history of the trade. Since January 1st, 1878, Chicago has received 4,184,715 live hogs against 2,591,479 for the corresponding period in 1877, and is now receiving over 15,000 per day. New York is receiving from 32,000 to 38,000 hogs per week. For the year ending November 1st the aggregate packing in the West will be approximately 9,700,000 hogs, an increase of 2,000,000 over the previous year. The summer packing, since March 1st to date, shows for this year a total of 2,856,032 against 2,193,633 for the same period in 1877.

—MR. W. H. LASCELLES, Horticultural Builder, Bunhill Row, London, has received the Cross of the Legion of Honour for his exhibits at the late Paris International Exhibition.

—A WRITER in the *North British Agriculturist* has stated that a good Ayrshire cow will give 520 gallons of milk, 480 lbs. of cheese, or 200 lbs. of butter per annum. She herself weighs about 850 lbs., and many instances are known where the annual milk product weighed six times the cow which gave it. Professor Arnold quotes one which, weighing 1080 lbs., gave from 6000 to 8000 lbs. of milk annually, that of 1874 being 8271 lbs.

—AN American writer on bees observes that nothing makes a bee-keeper feel so well as clean cash at the close of the season. White honeycomb in the "prize box" has only to be shown to be sold. The temptation is too strong to be resisted. The demand for honey is yearly on the increase. Formerly it used to be considered as an article of luxury or medicine, but the mass of the people are fast being educated to consider it an indispensable article of food.

STRAW HIVES.

IN noticing lately the oft-repeated condemnation of straw hives I happened to say that they were refused admission to a Crystal Palace show. This statement was made on a recollection of a conversation I had with Thomas Bagshaw, Esq., Longnor, Buxton, four years ago. He told me he had complained to Mr. Abbott (Treasurer), of the schedule of prizes being so one-sided, and against straw hives: that he had a large straw hive 20 inches wide filled by a swarm which he wished to put in competition in a class. He wrote to Mr. Abbott to see if it would be allowed to compete, and received for answer that his "query is a poser," but that he would consult his colleagues and send further information as soon as possible. The promised information came from Mr. Hunter, to the effect that the hive or hives could not be allowed to compete. This is what I understood about the matter at the time. As soon as I saw Mr. Hunter's letter in the *Journal* I wrote to Mr. Bagshaw, who is a gentleman of unimpeachable veracity, asking him if he would be kind enough to clear up the matter in a letter to the *Journal*. To-day, a letter from him to me to say

that he cannot remember the matter distinctly enough to enable him to write a public letter, and that he has not copies of his own letters to Mr. Abbott on the question, but will enclose what he can lay his hands on. Amongst the enclosures is a letter from Mr. Hunter, dated 15th August, 1874, which says—"Your query on Class 8 came whilst I was on the continent, and I understand that Mr. Abbott replied to it; however, the matter was mentioned to our Committee, and the opinion was unanimous that the produce of swarms must not be taken into account." This statement certainly does not indicate that it was the material of the hives that disqualified them for competition, but that they were filled by swarms. What Mr. Bagshaw thought then he thinks still and says, "There was an evident wish to exclude the straw hive by the arrangement of the schedule." If his hives were really not allowed to compete for other good reasons or on other grounds my statement that they were refused admission is not correct. If I were clear on this matter I would withdraw the statement at once and openly, and consider it a happiness to do so.

Mr. Hunter's letter says he has another grievance against me—viz., that, "I should be a little more particular before shifting my blunders on to his shoulders." Mr. Hunter is certainly under some misunderstanding here, for I never thought of or attempted to do such a thing. I never misquoted his figures, nor misrepresented the meaning of his book. "The 14 inches diameter," were correctly quoted by me eighteen months ago. In my own description I said 15 inches, but did not blame Mr. Hunter, or indicate by word or deed that he was at fault. If I were to make a blunder I would bear the shame of it myself; not on any account would I attempt to shift it on to the shoulders of anybody else.—A. PETTIGREW.

OUR LETTER BOX.

ROUP (Harold).—It is rarely cured. Wash the head daily, or twice daily, with tepid water. Give sulphate of copper, one grain, daily to each bird, mixed in oatmeal mashed with ale, and plenty of green food. Separate the fowl from all others.

GRASS PARRAQUET (E. G. B.).—The food you give may be varied. You may also give bread softened with milk, and any fruit the bird will eat. Above all let it have a bath daily. Fill a soup plate with tepid water, and let the bird bathe in it. If the bird does not take to the bath, pour the tepid water over it through the rose of a small watering pot.

CANARY PANTING (M. U. M.).—Put some Stockholm tar in his water. Feed on bread and milk and plenty of chickweed.

METEOROLOGICAL OBSERVATIONS.

CAMDEN SQUARE, LONDON.

REMARKS.

27th.—Little snow in early morning; rain throughout the day.

28th.—Another wet, dreary, dark day.

29th.—Fine frosty morning, bright sunshine; little foggy in afternoon and evening.

30th.—Dry, but thick and gloomy all day; fog in evening. Quite clear at 11 P.M.

1st.—Wet and gloomy with fog in afternoon; clear and fine after 7.30 P.M.

2nd.—Fair but dull, slight rain in middle of the day, brighter in afternoon, fine sunset tints; cloudy evening.

3rd.—Slight snow showers in morning, bright sunshine in middle of day; fair afternoon, and clear evening.

All the means of thermometric readings are below those of last week, and the mean of the barometer readings is also slightly lower. On the whole the week has been damp and foggy, though there were one or two fine days.—G. J. SYMONS.

COVENT GARDEN MARKET.—DECEMBER 4.

OUR market is now principally supplied with American Apples, larger quantities arriving each week, and prices being lower. English Apples are confined to late sorts. Some good Pears have reached us from California, consisting of Easter Beurré and Nelis d'Hiver, and have arrived in exceptionally good condition. Trade quiet.

From observations taken near London during forty-three years, the average day temperature of the week is 46.8°; and its night temperature 34.5°.

PETROLEUM AS AN INSECT KILLER.

THE inventors of many excellent insecticides deserve well of their country, and I hope they have realised handsome profits. If not, it is certainly too late in the day now, for none of the antidotes that I have tried can bear any comparison with petroleum for efficacy, cleanliness, and cheapness. Mealy bug, scale, and even the terrible red spider need frighten us no longer, for one dose will stay their progress and two or three will make an effectual clearance.

That petroleum or paraffin is distasteful to insects may seem a small affair to the uninitiated and even to the learned physiologist, but to practical gardeners who have to supply plants by scores of thousands it is of far greater importance than whether certain plants are carnivorous, or whether all of them absorb water from the atmosphere through their leaves; for however these great questions may be decided by learned men, it will matter comparatively little to the plodding gardener, whose practice already meets the requirements of the plants as far as these matters are concerned whatever may be the theory.

The discovery of this simple remedy for insects I do not hesitate to characterise as of greater importance to the gardening world than anything we have had for years. It is comparatively new to us, and therefore we do not yet fully estimate its value. But just realise the fact that the sponge, pointed stick, sulphur, soft soap, and all filthy compounds are superseded; that people with old tumbling-down houses and walls, which have hitherto been places of security for the greatest plagues gardeners are troubled with, are henceforth to be on a par as regards cleanliness with those possessing the best modern structures; that the syringe, which at present does so much harm in the hands of the inexperienced, may be used less and less; that in the busy spring, when there is often three days' work to be done in ten hours, and the insects show us no consideration, we can annihilate them almost in a moment at the cost of a few pence, and turn our labour to a more visible account; and it will be seen that it is no small blessing this simple discovery brings to us. Although I have satisfactorily proved the fact for myself, it seems too good to be true. We shall need to dream no more, when after some months' hard work of body and mind to get a house clean, that one of our assistants has broken a pot and replaced it with one from an infested spot; that another has tied up a shoot on a Cucumber plant where there was just a suspicion of spider and gone immediately into the early vinery to pull off a tendril or two, or some other similar little thoughtless act which destroys in a moment the work of months and even of years.

I daresay many people will lay claim to this important discovery, and possibly more than one may have hit on it at the same moment. I can only trace it to Mr. David Thomson.

The proportions to use are one wineglassful of petroleum to a gallon of water. They do not mix together well, but,

NO. 924.—VOL. XXV., NEW SERIES.

as has often been advised in "Work for the Week," if two or three squirts with a syringe are made into the vessel containing the mixture and then immediately one syringe-ful on to the plant, and afterwards alternately squirting one into the vessel and one on to the plant, it will be sufficiently mixed for all practical purposes. Thus used it will kill red spider and all but the very oldest scale, although its shelly covering has become somewhat hardened, while it it will not injure the tenderest Ferns. I have no mealy bug to try it on, but from what I have heard I have not the least doubt of its effect on that terrible pest.

Dipping the plants will not do so well as syringing. I had some Ferns dipped in a tub containing twelve gallons, and although one operator was agitating the mixture with a syringe all the time while another was dipping the plants, those first dipped appropriated all the oily substance from the surface of the water, and it remained on them some weeks and discoloured them. I do not think, however, it is this oily substance which is so fatal to the insects, but some other ingredient contained in the petroleum, and which mixes fairly with water, giving it a bluish colour; for the mixture was almost as effectual after the oily substance had disappeared.

Everyone who has used soap or alkali for plant wash (and most of the mixtures which have obtained popularity contain them), knows that the glass and paint with which they come in contact are soon injured, the glass losing its transparency and the paint coming off. As far as my experience goes at present petroleum does neither of them the least injury.—WILLIAM TAYLOR.

PLUMBAGO ROSEA.

SOME writers have condemned this plant as useless because it is not adapted for cutting purposes, nor suitable for the decoration of rooms; nevertheless it is highly worthy of being cultivated, especially by those who wish to have their houses attractive through the dreariest months of the year. Scarcely a flower is to be seen outdoors at this season of the year, therefore it remains for our stoves and conservatories to be made gay with flowering plants to afford the pleasure which our employers have the right to enjoy.

Forethought and care are necessary in preparing plants for winter decoration, and the gardener has often to wait from six to nine months or more before he sees the returns for his labour. The demand for cut flowers has increased considerably of late years, and oftentimes more are expected than can be produced with the means at our command; this may be why Plumbago rosea is not more generally cultivated. We prepare some plants for the adornment of our houses, and others for the decoration of rooms and for cutting purposes. We know of no plant more suitable, nor that lasts longer in bloom, nor produces a more gorgeous effect when grown in quantity than this Plumbago. Each flower certainly is short-lived, but the flowers are produced in succession—as soon as one is faded another is opened, and thus their beauty is continued for a long time.

NO. 1576.—VOL. LX., OLD SERIES.

Plumbago rosea is a very accommodating plant, and for the greater part of the season will flourish under the shade of Melons and Cucumbers; but we do not recommend that the plants remain in such a situation the whole season, or they would not bloom satisfactorily. A few details of our system of growing this useful plant may be useful to some readers. The plants are propagated in March and April; they root freely and quickly from cuttings of the soft young wood, and should be placed in a temperature of 65°, and shaded from the sun. They can either be inserted singly in small pots or eight or nine in a 5-inch pot. The former plan we prefer, for, the spring being a busy season of the year, if a number of cuttings are inserted together they are liable to remain too long and receive a check when separated. When the small pots are full of roots the plants are shifted as they require it until they are placed in 5 and 6-inch pots—this size being large enough for our purpose—using rich fibry loam, a seventh of well-decomposed manure, and sufficient sand to make the whole porous, as the plants require liberal supplies of water in all stages of their growth.

Being of upright habit old plants require to be cut back into the hard wood to cause them to break freely. When so treated they produce young shoots freely, six to ten of which may be left for flowering on plants in 6-inch pots. The growths should not be stopped after August. We remove our plants from the Melon house about the end of July or beginning of August and place them in cool frames, keeping them close for a time; there they obtain more air and light than in the house, yet they are benefited by slight shade during the hottest part of the day. They are well syringed morning and afternoon, closing the frames early so that the sun raises the temperature considerably. There they remain until the end of September, when they are removed to a house and placed as near to the glass as possible, where the temperature can be kept from 55° to 60° at night. After this their flower spikes soon appear: the plants are then liberally supplied with liquid manure.

One important point of culture is not to starve the plants while growing. If the growth show signs of being short-jointed it at once indicates that more heat is needed; this is during the time they are in cool frames. If the wood presents a stunted appearance the flower spikes are very short compared with those on plants more liberally treated. If well grown the plants produce small flower spikes for 1 foot or 18 inches down the stem, independently of the principal spike at the ends of the shoots.

Thrips and red spider are two enemies which attack them, but if the plants are kept growing freely and the syringe is well used the insects will do little or no injury.—WM. BARDNEY, *Norris Green, West Derby.*

GROWING GRAPES IN COOL HOUSES.

I VENTURE to remark that the ripening, not only of early but of second early, varieties of Grapes in cool houses has never been doubted by experienced Grape-growers. How could it be when it is well known that Grapes ripen out of doors in England as far north as the midland counties, and occasionally even farther north? A very slight rise in the mean temperature of this country will, it is well known, bring even our later kinds of Grapes to perfection, and with the aid of a glass house alone no one should have any difficulty in economising the natural heat to that extent; but the question is, Is it advisable to dispense with fire heat altogether?

I am not an advocate for artificial heat, and I dispense with it whenever I can do so with safety, but I confess the atmosphere of a cold glass house does not appear to me to be congenial to the Vine. I would much rather have the Vines on an open wall.

I never tried to ripen Grapes without fire heat, but I have seen them ripened often enough, both in the north and south, in cool houses, in greenhouses, and such like structures, but the success as a rule was not of an encouraging kind.

That terrible scourge mildew is the bane of cool houses; the damp muggy atmosphere generated in a cool house during cold weather is just the very condition necessary to produce it. I remember, a number of years ago, being told by a well-known London nurseryman who grew Grapes on the roof of his show house next the street, and which was never fired except to exclude frost, that he had no difficulty in having good crops of fruit, but they were always ruined by mildew. It was in July when I saw the Vines; a more distressing example of mildew I never saw, and I put it down to nothing else but the cold

muggy atmosphere of the house, reckoning from what I had seen of the disease elsewhere. Therefore, while not attempting to dissuade your readers from trying the "cool system" (for the saving in fuel is a great consideration) I would advise them to prepare for emergencies by having hot-water pipes in the vineries to be used if needful.—J. S.

PRUNING AND TRAINING WALL TREES.

ALTHOUGH it may not contribute to the fruitfulness of the trees whether they are trained with the branches straight or curved in zigzag fashion, yet a well-trained tree is an ornament, and ornament combined with fruitfulness should be the aim of the cultivator. The operation of pruning and nailing trees is often put off until midwinter (January onwards), which is neither suitable for the trees nor comfortable for the workmen. The work cannot now be done too soon.

In pruning Apricots any long bare branches should be cut clean out, not retaining more branches than can be trained-in without crowding, it being a common practice in Apricot culture to lay in an excess of young wood; the trees are then often only so many bare shoots with a few fruit buds at the end. The barest of these should be removed and the young growths spread out, so as to induce young fruitful wood and the formation of spurs. All young shoots should be trained in their full length, forerights cut back to within an inch of their base, and the short stubby shoots or spurs not shortened, the object being to keep the trees well furnished with spurs and young bearing wood as close to the wall as practicable. This will necessitate the renailing of the trees, a practice far too uncommon, and the re-arrangement of the branches, which often become bound by the shreds, the branches also growing round the nails, and gumming results.

Plums and Cherries produce fruit from spurs from the main branches, which are usually trained a foot apart. It is only necessary to cut back any wood growths to within an inch of the base and retain those 1 to 2 inches in length, these being mostly studded with bloom buds with a wood bud at the apex. Old trees are improved by a good thinning of the spurs, never losing an opportunity of replacing an old long spur by cutting back to growth nearer the base; but avoid anything like wholesale reduction, as that may not only reduce the prospect of next year's crop, but induce a quantity of spray difficult of being restrained. The thinning and shortening of the spurs must therefore be moderate.

Pears require to have all the wood shoots cut back closely, but any that have been stopped and have not pushed more than an inch or so of fresh growth may be retained, always presuming they are not more than that length from the branch they originate from. The spurs must not be touched, except they are much grown from the wall and crowded, when a judicious shortening and thinning is advisable. All extensions should be trained-in their full length, but the leaders must be cut back to 12 or 13 inches, so as to originate shoots at the proper distance apart. If the trees are not unnailed examine the shreds and nails, making sure that no branches are held too tightly and that the nails are not likely to injure them. If the trees show any signs of enfeeblement remove the soil down to the roots, picking it from among them with a fork, and replace with fresh turfy loam, with a fourth of well-decayed manure added and a sprinkling of half-inch bones (about a twentieth part), and if the soil be deficient in calcareous matter add a tenth part of old mortar rubbish or chalk well incorporated, the roots being laid in it and the soil made tolerably firm. If a good watering is given with liquid manure the trees will start all the more strongly in spring. If, on the other hand, there are more wood than fruit buds, bare the roots and sever some of the longest, retaining the fibres, covering them with the compost above named, omitting the manure, and giving a good watering.—A. G. P.

EXHIBITING CHRYSANTHEMUMS.

MR. TUNNINGTON'S letter on page 426 reminds me of the old proverb—"If you go to Rome do the same as the Romans." There is not, in my opinion, anything wrong in an exhibitor arranging his flowers on papers, but a dozen flowers so set up among hundreds without papers have a conspicuous appearance, and the stand alluded to at the Westminster Aquarium, to use a mild term, looked extremely unattractive. This was in part because the blooms were rough and of various sizes, and partly, perhaps, on account of the paper collars. No one,

I think, can imagine that the exquisite blooms of Mr. Sanderson in the same show would have been enhanced in beauty had they been shown on paper. Although the mode of exhibiting on paper may not be wrong, yet well-grown blooms of Chrysanthemums need no such artificial aids to display their beauty to the best advantage any more than do Roses, and yet a Rose show with the blooms placed on paper would present little short of a hideous appearance. The less artificiality there is connected with exhibiting flowers of any kind the better, and if the paper custom of Liverpool was done away with the show would not in the slightest degree be less attractive; yet I would not withhold a prize from meritorious blooms because paper had been employed in their arrangement.—A LONDON JUDGE.

LEMONS.

IN most gardens of any pretensions there are a few Orange trees grown, generally for ornament, but very seldom for use, because, as a rule, the fruit cannot be had of sufficient quality or quantity to be of service. This, I think, is more the fault of culture than anything else. Be that as it may, however, I find that Lemons can be cultivated more successfully than Oranges as a rule. The trees require no more attention, and they fruit more freely. As to their value, Lemons are always in greater demand in the kitchen and still room than Oranges, and I think if every gardener had a good Lemon tree or two they would find them as useful as any other fruit tree.

We have two Lemon trees planted out on the back wall of one of our conservatories from which we gather at least four hundred fruit annually, and as they are of a large size and very juicy they are much valued. Besides, we have ripe Lemons all the year round, and this is convenient in many ways: The trees are continually blooming and forming fruit, so that the supply is always kept up. The house in which they are growing is only heated sufficiently to keep out frost, and under this cool treatment we find the trees thrive better than in a warm house. The branches are trained on a strong wood trellis, and they are never allowed to become crowded. They are syringed sometimes to wash the dust off the leaves, but insects are kept away and the vigour of the trees sustained chiefly by attention to the roots. These have plenty of good loam and cow dung to work in, and at the same time they have often a large tankful of liquid manure emptied on them. The trees are thus kept healthy, and yet they are always fruiting so freely that the wood never becomes gross.

One Lemon tree trained on a surface of wall, say, 12 feet square would yield a large quantity of fine serviceable fruit, and any of your readers with small trees in pots could not do better than plant them out. A bed 4 feet square and 2½ or 3 feet deep is large enough to sustain a very large tree; if the root space is smaller than this, liquid manure and a rich surface dressing twice a year will do much good.—M. M.

DRESSING FLOWERS.

WHAT is all this about dressing flowers? Who is it that exhibits that does not dress, be it flowers, fruit, plants, or vegetables? Is somebody angry because somebody else wins? or is somebody too lazy to dress the flowers—that is, set them so as to look to their best advantage? or does he not know how? And if he cannot catch up and overhaul the old hands at the first, why, try again. One knows that in business the old hands and old established firms take a lot of beating; and I believe it is and always will be the same in exhibiting. Please pray don't grump because somebody else grows and shows—dresses, if you like, better than you do! What is the use of Mr. — wanting Roses to be shown without being disbudded? or Mr. — throwing up exhibiting and selling his boxes because he cannot win, or wanting special points for Teas? or Mr. — wanting Carnations shown as grown? Why, we shall be getting disqualified because the wind has whipped off some of the Rose buds and they look as if purposely disbudded, and all sorts of disagreeables, if such stuff and nonsense is to be introduced in the rules. He who can show best will win. Why not? And as for dressing, everything is dressed. Are not Grapes dressed—*i.e.*, shown to their best advantage? I fancy I remember seeing in our Journal in the autumn that somebody would have won only that "his Grapes were badly shown," rubbed, &c. Is not all other fruit dressed? I guess and calculate, as neighbour Jonathan says, that one would stand a poor chance indeed of winning if one's fruit

was jumbled up anyhow instead of being nicely arranged with leaves or moss, the best side outwards, and the best of all on the top. The same with plants. Would it look well for large and small plants to be mixed up without arrangement, shown as they grow—no training, no tying, no sticks, which are all dressing? Again, Cauliflowers and such like shown as grown! I wish prosperity and long life to horticultural societies and exhibitions; and for this, we *must dress*. Catch a fellow putting in a petal, or other swindle, then down upon him at once; but to say exhibitors must not dress—that is, clean, arrange petals in flowers, remove bad petals, cut out a damaged or mildewed Grape, or do anything else that will legally render one's exhibits more showable and less defective, cannot be prevented. Let us be broad and large in our principles. Let us say simply that any attempt at deception shall be punished, and let the rest alone. And as for Jones not winning because his soil is bad, or Smith not knowing how to set up his flowers, or Brown having a long journey by rail, while Robinson wins because his soil is good and can set up his flowers to win, and is close to the show, why Robinson is fortunate, but it will be my turn, perhaps, next time. Now I am about it, I think it decidedly bad taste to call So-and-so Hercules or somebody else Goliath, and set up Smith, Brown, and Jones as sure to win. There never was man so good but that another steps forward as good.—W. FARREN.

THE CULTURE OF DRACÆNAS.

VALUABLE additions have been made during the last few years to this important family of plants, both by the introduction of new species and by hybridisation. The beautiful colouring of the foliage and the noble yet graceful habit of the plants render them suitable either for exhibition or house decoration. It is a great advantage that a stock of these beautiful plants can be worked up in a very short time. In a young state their habit of growth is all that can be desired for the dinner table as well as their colour, which shows up magnificently by artificial light.

Dracænas are propagated in various ways, sometimes by cutting the old stem up into pieces about an inch long, and by fleshy root-cuttings. But the readiest way I have found to work up a stock is to take the old worn-out plants, shake all the soil from the roots, trim them in closely, cut the tops of the plants off and lay the stems lengthways on cocoa-nut fibre and sand in equal parts, covering them half an inch deep, where they will have the benefit of 75° or 80° of bottom heat. Give water sufficient to keep them just damp, and in a very short space of time they will emit shoots at almost every eye. When they have grown a few inches high and have emitted roots at their base they should be severed from the old stem with as much root attached as possible (when the old stem may be placed back again if more young plants are required), and potted into small 60-sized pots in a mixture of peat, leaf soil, and fibry loam in equal parts, with a little powdered charcoal and sand added. Plunge the pots in a bottom heat of about 75° until the plants are well rooted, when they should be placed on the surface of the bed. Dracænas may be propagated with success at all times of the year, but I have found the spring to be the most favourable season, as then there is ample time to grow the young plants into attractive specimens by the ensuing winter. The plants luxuriate in a brisk moist heat, and require to be shaded from strong sunshine, or they will not colour well. Great care must be taken not to overwater nor overpot them. Syringe once on bright days at closing time, working the syringe as much as possible under the foliage to keep down insects. After the small pots are filled with roots the plants should be shifted into 5 or 6-inch pots, as that is the usual size for decoration, using the soil a little rough, and which should now consist of equal parts of peat and turfy loam with a little charcoal and enough sand to keep the whole open. When the soil becomes exhausted a little of Standen's manure or guano should be sprinkled on the surface, which will prove very beneficial.

Where plants are intended for specimens those plants of the freest and best colour should be selected. Great care should be taken not to select those that are woody at their base, as such will never make good specimens. Or if there are large plants that have become leggy split a pot in halves, notch the stem of the plant, placing the pot round the notched part, fasten the pot with wire and fill it with soil. After the pot is well filled with roots the stem should be partly severed below the pot, and a week afterwards it may be severed altogether.

Keep the plant close and well shaded for a few days until it is well established and shift it on as required, using the soil of a richer character than that employed for smaller plants. Two parts of turfy loam, one of well-decayed cow manure, and one of peat or leaf soil with a liberal addition of charcoal and sand, will be a suitable compost; the pots to be well drained and a close watch must be kept for insects, as they speedily mar the beauty of the plants. By the methods of culture here detailed *Dracænas* may be propagated speedily and be grown quickly and well.

Those commencing the cultivation of these plants will find the following a good selection:—*Amabilis*, *Baptistii*, elegantissima, *hybrida*, *Goldieana*, one of the most distinct; *terminalis*, *terminalis alba*, *Frederici*, *Mooreana*, *imperialis*, *Taylorii*, *Baronii*, and *gracilis*.—A SOUTHERN GROWER.

DRESSING CARNATIONS AND PICOTEEES.

As the notice which you inserted from me was the commencement of the discussion which has continued for some weeks in your columns, I should like to again advert to it. In doing so I cannot but regret that personal feeling has been introduced into it. I attacked nobody, imputed no unfair or dishonest practices, and I am sorry that the tone of some of the communications has been characterised by a certain amount of bitterness. I must again repeat that I have no personal interest in the matter. I have grown in one way or another these flowers for a great many years. I never exhibited but one stand, and that was, as I have said, to show what undressed flowers were. It is immaterial to me who wins; indeed other matters call me far away at the time of the exhibition, so that I am not likely even to see it, and the opinions which I venture to express are only intended for the good of floriculture. Whether I am right or wrong in them I must leave for others to decide, but I am glad to find that an increasing number seem to agree with me, and on all sides I hear that the discussion will do good. Let me say it has done me good, for it has enlightened me a good deal on the subject of dressing.

In the first place we now understand that there are professional dressers who will undertake the duties of man milliner for those who have neither the ability nor time to manipulate their own flowers. Might it not be as well, if the system is to go on and flourish, that their names should be advertised? The tyro would then know where to go, not merely, as he may now do, for the tools by which it is to be done, but also for the artist who can use them.

Then it has come out that there are different styles of dressing. I was talking the other day to one of the exhibitors and a very good grower and dresser of these flowers, when he expressed his surprise at the position which one of our southern growers occupied, and he attributed his inferior position entirely to his mode of dressing. He said, "I have always thought his style of dressing—that of bringing them up full to the centre, the best; but the winning flowers were dressed much more flatly." I was told this was the northern style, and as I believe the judges were northerners it is easily accounted for." Of course this is a matter which cannot be helped; the fancies of judges are manifest in most exhibitions, and exhibitors have to take account of it. Only the other day I heard one of our very best poultry judges say he had given up judging, for he would not stand the whims and caprices of those who set up standards which he could not agree with. And so it would seem that exhibitors of Carnations and Picotees must not only be able to dress or get others to dress their flowers, but even then it will be a lottery as to who shall win, just as it is to the exhibitor of Dorkings whether the judge likes a dark or light-coloured bird.

There have been various attempts during the discussion to get off into side issues—to attempt to class the dressing of these flowers with the thinning of Grapes or arranging the growth of pot plants. This is really too good, and can only deceive the very simple; the truth being that this practice is, in the extravagance to which it is carried, totally different both in principle and detail from that to which any other flower is subjected. Then, again, a great deal has been made of the question as to whom the merit of a prize is due, the grower or the dresser. This was merely a secondary matter, and was asked more in fun than seriously: my wish was certainly to keep the discussion on the main lines.

I have read nothing that in the least degree alters my views. This may be owing to my density of understanding; but I would observe that it is no argument to say that a practice is

old. So are a great many things that would be more honoured in the breach than the observance. Is it not better, even although it be old, to see whether it cannot be altered? It is evident that there are some varieties which can be shown without dressing, that have long pods which do not split, that are not overcrowded with petals half of which have to be abstracted before the flower is presentable. Let raisers set themselves to give us such flowers as *Edith D'Ombra* and others of a like character. Let it not be said it cannot be done. "Cannot" ought not to be in a florist's vocabulary, and when I recollect what has been done in other flowers I am sure it can be in these. I remember when first it dawned on *Chrysanthemum* exhibitors that an incurved flower was the thing to aim at, and I recollect what dodges used to be resorted to in order to twist into that form flowers that had some inclination to it; and now we have, as the result of the hybridisers' efforts, flowers so completely incurved that they are a complete ball. Then, again, I remember when the *Gladiolus* was first shown, that it was evident that the best style of flower was that where all the flowers faced one way and were not winged. Here too I remember the dodges which were resorted to and recommended to effect this; and now—well, in some of Mr. Kelway's latest seedlings the flowers so completely face one way, and are so closely packed into one another, that you can hardly get a pencil in between them. Some of us ridiculed the plan of showing in those days, even placing them in *Yucca* leaves or running pieces of wire behind them, and we were "sat upon" for so doing; and now we have our revenge. People would no more think of doing these things than of showing them upside down. It may be—I may not see it—but I am equally sure that the time will come when persons will look back with a smile to the days when they were obliged to torture and manipulate the Carnation and Picotee, and in a newer race of flowers see that which we are now contending for carried out.

One result of this discussion is pleasant to me as an old florist. I never again expected to see a communication from so old and able a florist as Mr. Slater, one who knows more than anyone living of the past history of Auriculas, and Carnations, and Picotees, and whose name was at one time so prominently before the public. I see that in the calm of an honoured old age he has still some enjoyment in the thoughts of the past, one of the pleasant things connected with the pets we cherish and love.—D., *Deal*.

LAWN SAND—PETROLEUM STOVES.

I TRIED the effect of lawn sand some five years since. A small quantity was procured for experiment, a piece of grass carefully measured, and the sand weighed and applied strictly according to the instructions. In a few days both grass and Daisies appeared to be killed, but the grass soon began to grow again very luxuriantly; so much so that if allowed to grow for a week the machine could not cut it, and being also of a very dark green the patch presented a remarkable contrast to the rest of the lawn. What few Daisies, &c., appeared to escape the first dressing were afterwards treated to an extra pinch, and the result was considered a great success; but the following spring on the piece so treated the grass was as poor, and I believe poorer, than on any other part of the lawn, and the Daisies as plentiful and rampant as ever.

A question is often asked about heating greenhouses by means of petroleum stoves. Four years since I was asked to look after a house newly erected. Seeing no means of warming I inquired what was going to be done. I was told a paraffin stove was ordered. I expressed strong doubts as to its efficacy and safety, but was overruled, and it duly arrived and was put into use. The plants soon began to look very sickly. I blamed the stove. The lady believed that one stove was not sufficient for the size of the house, so another was procured, and that completed the failure, for by Christmas there was not a green leaf in that greenhouse except on a few Ferns and Primulas, which did not seem much affected.

The stoves were then banished, a small coil boiler and some piping introduced, and in a very short time the plants put forth new leaves, and it once more looked like a greenhouse, to the great satisfaction of all concerned.—J. J., *Lancashire*.

MEDLARS.

IN Dr. Hogg's valuable "Fruit Manual" three Medlars are described; the Broad-leaved Dutch, Nottingham or Narrow

leaved Dutch, and Stoneless. The one we grow and prefer is the Narrow-leaved Dutch. Grown as a standard bush with a very large head it never fails to bear a heavy crop of evenly sized fruit about 2 inches in diameter. The blossom is not so easily injured as that of the Apple in spring, and the trees will succeed in any exposed place and in nearly any kind of soil. We never prune ours further than thinning out the branches, and the surface of the soil over the roots is dressed every year or two with decayed manure. The fruit is gathered about the beginning of November, and laid out in the fruit room along with Apples, Pears, &c., and during December, as soon as it becomes soft, it is used for making jelly and for dessert. The fruit is so much relished for both of these purposes that no garden where fruit trees are grown should be without a Medlar tree. When space cannot be given it in the kitchen garden it is quite ornamental enough to be planted in the pleasure grounds.—A KITCHEN GARDENER.

REVIEW OF BOOK.

English Folk Lore. By T. F. THISTLETON DYER, M.A., Oxon.
London: Hardwicke & Bogue, Piccadilly.

ON laying down this book after a careful perusal of its pages one conviction was forced upon our minds, and that was that we were strangely ignorant of a great deal that is or appears to be "folk lore." We were not aware that so much superstition was still lingering in our midst. To read of charms for fits and charms for lovers we were prepared, but not to find that each day of the week, each month, and each new moon had its particular superstition.

Mr. Dyer divides his book into thirteen chapters, which may be classed under three heads—plants, animals, and the folk lore which concerns human beings. The chapter on plants is very interesting, and as this is the one which most concerns our readers we will give a few quotations from it.

Mr. Dyer lays down a rule that flowers form an important part in the formation of character. The purity of childhood was symbolised by the early Snowdrop, from its exquisite and virgin whiteness; and the Harebell was, on account of its delicate blue colour, considered typical of truth. It will be a surprise to many of our readers to know what a great deal of superstition attaches to the simple garden vegetable Parsley. Plutarch tells us how a few mules laden with Parsley threw into a complete panic a Greek force on its march against the enemy, and the reason was that the Greeks used to bestrew the tombs of the dead with this herb. In Devonshire it appears to be believed that to transplant Parsley is to commit a serious offence against the genius who presides over the Parsley beds, which is sure to be punished either on the offender or one of his family in the course of the year. In Hampshire the peasants refuse to give any away, and in the neighbourhood of Cobham (Surrey) it is believed that if Parsley seed is sown on any other day but Good Friday it will not come double.

The Rose also was largely used by the Greeks and Romans for funeral purposes, and the tombs of the dead were frequently decorated with them. Camden and Aubrey both speak of the churchyards in their time as thickly planted with Rose bushes. In Wales it is the custom to plant the white Rose on the grave of an unmarried female, and a red Rose is appropriated to anyone distinguished for benevolence of character. It is also considered very unlucky to scatter the leaves of a Rose on the ground, and an instance is given of Miss Ray, who was murdered at the Piazza entrance of Covent Garden Theatre, who, as she picked up a lovely red Rose which had fallen from her dress, was much troubled at seeing it fall to pieces, saying, "I trust I am not to consider this an evil omen."

In South Lancashire, Rosemary to this day is carried by the mourners at a funeral, and in Wales it is customary for funerals to be preceded by a female carrying sprigs of Bay, the leaves of which she sprinkles on the road which the corpse is to travel. A flowering Myrtle is believed in Somersetshire to be a great acquisition to a house, and with regard to this plant a singular superstition exists. In the *Athenæum*, February 5th, 1848, a correspondent says, "Speaking to a lady of the difficulty which I had always found in getting a slip of Myrtle to grow, she directly accounted for my failure by observing that perhaps I had not spread the tail or skirt of my dress, and looked proud during the time I was planting it." It is a popular belief in Somerset that unless a slip of Myrtle is so planted it will never take root.

It is a common notion, so says Mr. Dyer, that in leap year Broad Beans grow the wrong way—i.e., the seed is set in

the pods in quite a contrary way to which it is in other years. With regard to lovers there are numerous ways given of finding out whether they will succeed or be true to one another. One is by carrying bachelors' buttons in their pockets. They judged of their good or bad success by their growing or not. A practice called "peasod wooing" was formerly very often to be met with. The cook when shelling green peas would, if she chanced to find a pod having nine, lay it on the lintel of the kitchen door, and the first man who entered was believed to be her future husband. In Cornwall with regard to healing plants, the Club Moss (*Lycopodium inundatum*), if properly gathered is considered good against all diseases of the eyes. A decoction also of the Nettle is a favourite prescription among country women for consumption, and in Scotland there is a rhyme—

"If they wad drink Nettles in March,
And eat Muggins [Mugwort] in May,
Sae mony braw maidens
Wad not go to clay."

The Ivy, too, is a healing plant. In Shropshire children affected with whooping cough are allowed to drink all they require out of drinking cups made from the wood of the common Ivy, this being considered an infallible remedy. The passing of children through holes of trees to cure certain complaints is still practised, and in Cornwall there is in the parish of Madron a curious Druidical remain known as the "Stone of the Hole." This is an upright circular block of granite, and in its centre has a circular hole. Through this children were passed a certain number of times, under the notion that this would cure them of the complaint from which they might be suffering. Plants are also good barometers. Clover Grass is said to seem rough to the touch when stormy weather is at hand. Heliotropes and Marigolds do not only presage stormy weather by closing their leaves, but turn towards the sun's rays all the day, and in the evening close.

An opinion prevails in many parts that an Elder tree is safe from lightning, and the *Stamford Mercury* in 1861 relates that when the electric fluid struck a Thorn bush in which an Elder had grown up and become intermixed the Elder escaped unscathed, though the Thorn was completely destroyed.

There are many traditions as to the wood of the cross on which our Lord was crucified. The most common belief is that it was made of Aspen (*Populus tremula*), and that the leaves have trembled ever since at the recollection of their guilt. In the west of England there is a tradition that the cross was made of Mistletoe, which until this time had been a fine forest tree, but was condemned henceforth to lead a parasitical existence. The gipsies believe that the cross was made of Ash, while some believe that it was made of four woods, signifying the four quarters of the globe or all mankind, and consisted of the Palm, the Cedar, the Olive, and the Cypress. Another superstition is that the cross was made of Elder, and that Judas hung himself on an Elder tree. In Cheshire the Arum maculatum is called Gethsemane, because it is said to have been growing at the foot of the cross, and to have received on its leaves some drops of blood, and in Scotland it was formerly believed that the dwarf Birch is stunted in growth because the rods were formed of it with which our Lord was scourged.

The book is a most interesting one, and will well repay perusal, for it is not only full of instruction but abounds in anecdotes, many of which are exceedingly amusing. As a sample we will give this one from the chapter on charms:—"Sir John Holt, who was Lord Chief Justice of the Court of King's Bench in 1709, who it is said was extremely wild in his youth, and being once engaged with some of his rakish friends in a trip into the country in which they had spent all their money, it was agreed that they should try their fortune separately. Holt arrived at an inn at the end of a straggling village, and strolled into the kitchen where he saw a little girl shivering with ague. Upon making inquiries he found that she had been ill for a year, notwithstanding all the assistance that the mother could procure from physic. He gravely shook his head at the doctors, bade her be under no further concern, for that her daughter should never have another fit. He then wrote a few unintelligible words in a court hand on a scrap of parchment, and rolling it up directed that it should be bound on the girl's wrist, and there allowed to remain till it was well. The ague returned no more, and Holt having remained in the house a week asked for his bill. 'God bless you, sir,' said the old woman, 'you be nothing in my debt, I'm sure.' With pretended reluctance he rode away without paying. Many years elapsed, and Holt advanced in his profession. One day

when sitting as judge on circuit an old woman was brought before him charged with witchcraft. To support the accusation several witnesses swore that the prisoner had a spell with which she could either cure such cattle as were sick or destroy those that were well, and that the spell was now in court, upon which statement the Judge desired that it might be handed up to him. It was a dirty ball, wrapped round with several rags and bound with packthread. These coverings he carefully removed, and beneath them found a piece of parchment, which he immediately recognised as his own youthful fabrication. For a few moments he remained silent, then told the jury the whole story, with such effect that his old landlady was the last person tried for witchcraft in that county."

CARPET BEDS.

In their estimates of carpet beds some admirers give the palm to simple designs, others prefer patterns more intricate.

Fig. 67.—Carpet Bed at Regent's Park.

1. *Dracæna australis*.
2. *Coleus Verschaffeltii*.
- 3, 3. *Pyrethrum Golden Feather*.
- 4, 4. *Alternanthera amabilis*.

- 5, 5. *Echeveria secunda glauca*.
6. *Alternanthera paronychioides*.
7. *Alternanthera amœna spectabilis*.
8. *Mesembryanthemum cordifolium variegatum*.

9. *Echeveria metallica*.
10. *Lobelia pumila grandiflora*.
11. *Autannaria tomentosa*.
12. Box edging.

The diagram annexed is of a bed that was highly approved of in Regent's Park last year, and is noteworthy by the delicate tracery of its pattern and its general artistic appearance. It was tastefully planted, as may be seen by an examination of the figures and corresponding references. Apart from the applicability of the designs for a round bed the tracing of it by young gardeners during the long winter evenings would be commendable employment, as competency in geometrical drawing is an important element in a gardener's qualifications. Every young man aspiring to the position of a skilled gardener should persevere until he can draw the pattern of this bed readily and correctly.

AUTUMN RASPBERRIES.

AUTUMN-BEARING Raspberries are well worth cultivating, even where the conditions of soil and climate are so unfavourable as to make the returns both small and uncertain. Raspberries in the two last months of the year—sometimes in mild seasons even a dish at Christmas—are something worth running the risk of occasionally losing both a little ground and labour

for. Of course they are neither so large, nor in the best of seasons is the flavour to be compared to that of the summer sorts, but coming in as they do on the verge of the dead season, when all other small fruits are past, it is only reasonable to suppose that were they better known they would be more extensively cultivated.

Nurserymen catalogue several sorts, but that known as the October Red appears to be the most useful. Certainly here in the west of Scotland it is the only one that I have seen do anything like well, but my acquaintance with the other kinds is very slight.

The best time to form a new plantation is from the middle of November up to the present time; but they will do fairly well planted any time during the winter. A warmer and more sheltered situation should be given them than is required for the summer-bearing sorts, say a border on the south side of a good Beech or Holly hedge. This is even preferable to a wall, as the heat there is not so intense in summer, and the shelter in autumn is quite as good. This border should be trenched to a good depth—not less than 2 feet at least, and well manured at the same time with rich dung. The plants may be put in rows across the border 2½ feet apart, and allowing not less than 4 feet between the rows. Any closer planting than this, even in a small garden, is not in the end economical. The canes that are planted should be allowed to remain until they are in leaf, as they help to spur the roots into action, when they may then be cut off close to the ground, as it is the canes of the current year which produce the fruit. The crop the first autumn will be *nil* or next to it, and the canes should all be cut down in December. If many suckers have been thrown up between the rows they should be carefully forked out, but anything like a general deep digging should be avoided, a good top-dressing of decayed cow dung being much preferable.

This propensity for sending up numerous suckers far and near is one of the worst traits in the character of the October Red Raspberry, and if any semi-natural system of cultivation be attempted a fruitless thicket is sure to be the result.

When the young canes have grown 6 or 8 inches in spring, half a dozen of the strongest on each stool should be selected and tied up to a stout stake, and the others cut away, as also should be all succeeding shoots which appear during the summer.

The other sorts most commonly grown are the Autumn Black, the Large Orange, and the October Yellow, which is a variety of the Red, but more insipid. The

October Red is said to be a cross between the old Double-bearing Red and the well-known Fastolf.—R. D. TAYLOR.

THE ROSE ELECTION.

IF Mr. Hinton will not think me too late in doing so, I beg to tender him my acknowledgments for the pains he has taken to bring the election of 1878 to such a successful completion, and I feel sure there must be hundreds who, like myself, have read with very great pleasure and satisfaction the weekly contributions that have appeared in your Journal. And when we consider that Mr. Hinton's task has been purely a labour of love, we must all feel deeply indebted to him for the trouble he has taken to make the election as complete and useful as possible. Useful I said, for has not a "WILD SAVAGE" acknowledged its utility? Then how much more must civilised and rational people do so?

Of course there are Roses omitted and others included in the list which some of us no doubt have thought might have been otherwise arranged; but taking into consideration the varieties of soil and climate, the differences of aspect and situation,

and the variety of opinions on the colours, shapes, &c., of Roses, it is no marvel that in choosing the best forty-eight kinds no unanimous opinion was come to.

I am not quite sure what is meant by the best forty-eight Roses. I gather that the respective electors have voted for those varieties that grew and bloomed the best in their own neighbourhood, and not for the intrinsic merits of the blooms alone. Such voting, in my very humble opinion, must always be unsatisfactory to the general world of rosarians, inasmuch as while a Rose may grow healthily and vigorously with A, it may barely be able to exist with B, and as a consequence receives A's vote, whilst B gives his to one that does better with him. Under such circumstances we need scarcely wonder at the want of unanimity amongst the electors; but taking the election as it is, possessing as it does the opinions of so many competent judges, and from such a variety of soils, &c., no one can doubt its value to a very large class of Rose-growers, and there are few lovers of the Rose who will not derive some information from the election and the discussion which it has brought about.—F. BOYES, *Beverley*.

WOOD FENCES FOR FRUIT-GROWING.

To secure the advantages of a wall for a reasonable length of time at a less cost is what we must aim at in the matter of wooden fences. To be secure against wind must be one consideration, and as durable a post as possible another. For a close fence posts ought never to be less than one-third their length in the ground; if less, unless stayed, the wind is certain to move them. Of English wood oak undoubtedly is the most durable, although sapling Oaks with only 1 or 2 inches of heart are certain to go at the surface the second year. The disadvantages of oak are its cost, its aptness to split whilst nailing, and its being too hard to drive a nail into when dry. Larch is by its toughness suitable for nailing; and a post not overstripped from the heart of a Larch tree will stand at least for twenty years. A sapling Larch—but to a much less extent—has the same failings as has the sapling Oak, yet for gates and railings it will withstand the effects of the weather for many years. Sycamore is the least durable; and of hard woods beech is the next that will not stand being wet and dry for two seasons; whilst for any purpose constantly dry it is durable, and for any purpose always under water it is as durable as oak. Elm makes a fair post, whilst ash is little better than beech.

In advising for the best fence for our purpose I will suppose that I have everything at my command. If the fence is to be 6 feet 8 inches I would have larch posts 6 inches square. The portion below the surface might be left round, the better to afford a good charring, and then you have a small portion of charcoal for the roots of the trees for nothing. Failing larch I would procure a 7 by 2½ inch red wood batten or Norway red wood scantling—perhaps the cheapest wood imported. I would fix my posts in the ground 8 feet apart, being careful whilst setting them to have a lath of the exact length to lie between post and post. I would have them 8 feet to an eighth of an inch, and make sure of having them well firmed at the bottom—this is the secret in setting firm posts. A piece of wood nailed across the bottom of each post would add much to their stability. I would then get a batten cut in the manner that the timber merchant would understand by five "rips," "cuts" means cutting the deep way or into deals. Then each of these six laths I would cut diagonally. One of these laths I would nail level with the face of the post at each side, and nail the other within to leave a groove 1½ inch broad, and the thickness of the angle lath would secure their being 1 inch deep.

Coping boards being desirable, the next task would be to fix a scantling along the top to secure them to. These scantlings would be from 25-feet battens one rip; this would leave them 3½ inches by 2½ inches. These would reach three posts, and allow the wood being cut without waste. The posts being all fixed I would mark each post on the scantling with a pencil, and then notch them at the posts half through; and, this done, would nail them on the top of the posts, the face of the fence to be level with the inside of the groove on the posts. Being marked at the bottom and nailed on the top would secure each post being parallel. I would then stretch a line along the face of the posts just above the ground level and sight it, being particular at necessary intervals to raise it up straight. Marked from this line I would cut all the angle pieces forming the grooves—that is, the ends that might be

below the surface. I would next nail a piece of wood about 2 inches thick close up under the angle beads to form a bearer for the boards; of less thickness it would be insufficient, as the weight of all the boards would rest upon it. I would next secure, at about 1s. 2d. per yard, tongued and grooved flooring deals in 16-foot lengths and 1½ inch thick; seven-eighth-inch deals at about 2d. per yard less would soon have their grooves damaged. With a lath the length between each two posts I would mark the deals, then cut them, slide them down the grooves on the posts, making sure to have the tongued edge of the deals uppermost to prevent wet lodging. The advantage of this fence is, there will be no open joints for north winds to injure Peaches, &c., when in blossom; let the sun be ever so hot the joints would always be close. Plain-edged deals would answer the same purpose, but the sun warping them they would not be so neat. By having the bearing pieces carefully lined before fixing the joints of the deals would be straight from end to end. If done in the winter season the deals should be level with the top of the posts, then what they shrink in summer more than the depth of the notch of the scantling would be of no importance.

The coping I would procure from 17 feet 11 by 3 inch deals two cuts, or I would have them broader if considered necessary. For each coping board I would have three tail hinges with crooks, the latter being rabbeted into plates to admit their being screwed on to the top of the scantling; this would prevent the scantling being split, and the tail of the hinge being screwed across the coping board would strengthen it and also prevent it from splitting. Hinges and crooks would allow the coping to be slipped off when it was unnecessary; in fact they might be used as shelving for, say, ten months in the year. An angle stay secured to each post by loop and staple, and staples rabbeted into plates the same as the crooks, and then securely screwed to the coping-boards, would be quite sufficient to secure them. The end of the stay to go up next the board would require to be bent, then a wood slot would make it all secure.

To fix wires down the face of the posts is easy. Secure one end of the wire, wrap the other round a piece of round wood, and then stretch by getting hold of any of the posts, drive a staple at each post, and in a few minutes the work is done. The posts for a very exposed place may be closer if preferred. Make certain at least once a year to coal-tar each post 6 inches above and below the surface: this will double their durability. One advantage of a wooden fence is its being easily removeable, and whilst quite as good much less expensive than a wall. I have done my best to contract my remarks and yet to allow them being understood, which it is not always easy when reading about anything that is not previously known.—J. WITHERSPOON, *Chester-le-Street*.

SCOTTISH HORTICULTURAL ASSOCIATION.

The monthly meeting was held on the 3rd inst. at 5, St. Andrew Square, Edinburgh. There was a large attendance of members. The President occupied the chair. After the election and nomination of new members Mr. L. Dow read a paper on the kitchen garden, being the continuation of his former paper on this subject. He again urged upon the attention of young gardeners the great importance attaching to this part of their profession. The operations of the kitchen garden he described in a clear and lucid manner, such as trenching, manuring, and cropping, and detailed his system of cultivating the Cauliflower, Pea, Carrot, and Turnip. The various difficulties attending the Carrot crop on many soils were referred to; but to remove these obstacles in a great measure he approved of deep trenching and deep manuring, a dry bog being the soil best adapted for the growing of this vegetable. Mr. Dow also spoke of the shaws of Swedish Turnip as being a good substitute for Seakale, and strongly recommended it as being more economically and easily managed.

Mr. Robertson Munro next read a paper on "Hardy Spring Flowers," which included all those flowering from January 1st to May 1st. He spoke of the neglect by many gardeners of these beautiful flowers, and said that more time and interest spent upon some of the best kinds would well repay any extra labour given. It was one of the prettiest sights to see some of the rarer gems of this class of plants with their pure colours coming into flower when the ground was coated with snow and vegetation for the most part lying dormant. The cheery aspect they presented at this dull season was welcome to lovers of the beautiful. Mr. Munro then named the most popular kinds, and explained the treatment of those that required careful and particular cultivation. The following are some of the plants referred to—*Helleborus* sorts, *Snowdrops*, *Iris reticulata*, *Cyclamen* com and varieties, *Winter Aconites*, *Scillas*, *Sisyrinchiums*, *Leucojums*, *Hepaticas*,

Anemones, Myosotis, Crocuses, Daisies, Primula and varieties, Aubrietias, Saxifrages, Tulips, &c.

Messrs. Downie & Laird sent a nice pan for exhibition of the *Sibthorpia europæa variegata*. Messrs. Dickson & Co. exhibited two stands of cut blooms of *Chrysanthemums* containing sixty-three varieties which included all the favourite kinds, and a fine bloom of *Thunbergia laurifolia*. Mr. John Webster exhibited a new seedling Apple named *Beauty of Moray*, a culinary Apple, free bearer, and long keeper.

FRAUD AT THE LIVERPOOL SHOW.

YOUR reporter sent you a correct account of the above Show. Mr. Ollerhead in his letter in your contemporary only reported the black side, and left entirely out the notes taken in the early part of the day of the productions worthy of comment. We question very much if *Chrysanthemums* were ever shown in better condition, either in London or elsewhere, than those at St. George's Hall on the 20th of last month, either trained plants or cut blooms. All interested in the Exhibition are truly sorry that a solitary instance of unfair exhibiting should have occurred, and express their deep regret that fraudulent blooms were brought to the Exhibition. The young man in question is a good grower, and from what we saw of his blooms only a few days prior to the Show he was well able to stand his own ground in the contest without any such trickery.

To turn to another question, How came the Judges to pass such abnormal blooms and to give to them the first prize, and what is to be the guide for Judges? We are informed a stand of blooms (incurred varieties) with Fingal and Faust in the south of England would be disqualified; they are incurred varieties, and were two of the finest blooms in the Show. Judges should be able to know each individual flower, its conditions and its qualities, before the awards are made. The fraternity in this neighbourhood cannot all be regarded as capable of fraud and trickery.

The competition independent of the impostor's blooms was good, and even after the blooms had been put two and three in one Mr. Tunnington's were far superior, and I believe Mr. Ollerhead saw them before they were staged. We can point to Mr. Tunnington's and Mr. Elliott's blooms and others being shown honestly and fairly, and with such blooms the south-country growers were nowhere.

Liverpool as a *Chrysanthemum*-growing district is able to contest honestly and fairly with growers from any part.—
W. BARDNEY, *Norris Green, West Derby.*

AFTER what we have seen at Liverpool on the 20th of last month in regard to the judging of cut blooms of *Chrysanthemums* we do not wonder at Sir Henry Peek asking the question, "Who were the Judges?" We are also in doubt as to what are the points of merit to be considered before awarding a prize. Our ideas in judging *Roses* or *Chrysanthemums* are—first colour, second symmetry of form, third size of petal in relation to the variety, fourth and last size of bloom in relation to variety. Summing up these four points we think a correct decision may be given. Judging the blooms by the above test by a jury and calling four witnesses, we are then justified in condemning the awards of the Judges at Liverpool. We are quite at a loss to know on what principles the premier prize was awarded to the stand that in a few hours afterwards was disqualified by the Secretary and Committee. There was only one bloom in the whole twenty-four that bore the character of a *Chrysanthemum*. Whoever saw *Empress of India* grow in shape like a Pine Apple, or Queen of England like an Irish haycock, or Golden Beverley like a Globe Mangold, and Alfred Salter and Jardin des Plantes like the cones of *Picea nobilis*?

Mr. Ollerhead's letter referred to by Sir Henry Peek is a correct account as far as the fraudulent stand was concerned, but he does not give other exhibitors the credit of showing honestly. I was standing close by Mr. Ollerhead while the delinquent's stand was undergoing examination, and heard, as he must have done, the other exhibitors offer their stands to the Committee and Secretary for examination, which was objected to on the grounds that no protest had been lodged against them. Why, then, did Mr. Ollerhead not lodge a formal protest against other stands if he had a suspicion of the integrity of the blooms? I submit that as he did not do so he ought in justice to others to state plainly that his suspicion was limited to the disqualified stand. The letter as it stands conveys an unpleasant impression affecting the whole of the exhibitors.

As to who was the first to make the discovery of the fraudulent blooms it is difficult to say, but it is certain that many exhibitors were equally anxious that any unfair exhibiting should be officially denounced. It is certain that a lady who takes much interest in the cultivation of the *Chrysanthemum* hinted that there was something wrong early in the day; that, however, is a comparatively trivial matter. Of much greater importance is it that the public in this case must not infer that one black sheep infects the whole flock.

As was correctly stated in the Journal last week Mr. Roberts did not take first honours last year. In 1877 Mr. Tunnington was first, in 1876 Mr. Meerse, in 1875 Mr. Elliott, and I think Mr. Norrie was first in 1874.

If Mr. Ollerhead or any other southern *Chrysanthemum* grower has any suspicion about our honesty they have only to give us an invitation, and we will meet them in a friendly manner next year at any *Chrysanthemum* show out of London, or even in London, if they make their schedules more explicit and give us a list of names, so that we may know exactly what varieties to put in our stands.—ALLERTON.

SPECIAL reference having been made to the blooms that I exhibited at the above Show, and also of the proceedings I took against the first-prize blooms, I think it is only fair that I should have a say in the matter. The blooms were not staged until twenty minutes past twelve, the whole collectively in the different classes for competition numbering three hundred—viz., seven twenty-fours, two eighteens, six twelves, and four sixes, all incurred; to which may be added a stand of Japanese, not for competition, by Mr. Tunnington.

At a glance I could see that large blooms of no matter what quality were the aim of all exhibitors, and this I remarked to several bystanders, including the Secretary. The latter gentleman said, "Yes, we go in for size at Liverpool. One year we went in for neat compact blooms. I forget now who were the Judges, but there was a great deal of dissatisfaction about it, so we always stick to size now." I said at the time it was hardly fair; it was like putting overgrown Drumhead Cabbages against good useful kinds. Mr. Tunnington had shown me twelve of his blooms earlier in the day, and asked me the name of one he did not know, adding, "I suppose your blooms are double the size of these." "Oh, no," I replied, "my blooms are smaller than yours." When the first six stands were staged and he saw I had told him the truth, he said, "Well, now, how do you think we stand?" and Mr. Peerse, who staged next to me, also requested my opinion of his blooms. I glanced along the stands, which for the first-prize holder did not require much consideration. I told Mr. Tunnington he was first by a good few points, but Mr. Peerse I thought would be nowhere. He had a grand bloom of Barbara, but the others were all flown; some of them were so open they would have taken a fair-sized bloom of Mrs. G. Rundle to fill up their centres. I know Mr. Peerse must have felt much annoyed at my verdict, nevertheless it was my candid opinion, and, I added, they remind me of overgrown split Cabbages. Had they been full in the centres they would have been monsters. I believe Mr. Tunnington at this time was quite satisfied he would be first. The officials were busy clearing everybody out, when Mr. Wallis of Keele Hall wished to know which were mine. I pointed them out, adding, "They are no use; they go in for size here, quality seems entirely out of the question, and in that case I shall be nowhere." He replied, "They are an even lot, and very neat; I don't think I ever saw such a pretty lot. The others are too coarse." On leaving the Hall and in going down the steps I found I had not put my ticket on the stand, which I ran back with, and had another clear view of the blooms. It was then that I first noticed the small petals around the middle of Mr. Roberts's blooms, which had a very strange appearance. On my return I told Mr. Hinds I did not think much of those that were last staged, they seemed as though they had made a double growth and had a lot of small petals around the middle of them, which I could not understand. He said, "Well, it is curious the freaks and forms that Nature takes sometimes, and it is not always easy to account for them."

On our return at four o'clock we went to see who had the prizes, when to my unutterable astonishment Mr. Roberts was first with those ugly blooms. I at once expressed my opinion in the matter, and made the following notes:—"Class A, first prize Mr. F. Roberts. The only good bloom on the stand one of Gen. Slade; the others look as though a double growth had taken place, which is very conspicuous in the blooms of Queen of England,

Alfred Salter, Empress of India, and Golden Beverley by a whorl of small petals formed around the middle of the blooms. Such a stand not in the hunt." I put my pencil in one of the blooms for an examination, when I was politely told by a looker-on if I interfered with them blooms I should have my head punched. I need hardly say that I did not fear the threat, but only waited another opportunity. I expressed my opinion to many respecting the blooms that they were not genuine, but no one seemed to care to go into the matter until about six o'clock, when I examined three blooms, and strange to say I was again told by an on-looker that he had a good mind to punch my head!

Having satisfied myself as to the fraud that had been practised I at once took proper proceedings, wrote out the protest, and had an investigation in the Committee-room. It is only proper to say that I do not believe there were half a dozen present who were satisfied that the blooms were made up until after the investigation was commenced. Mr. Elliott, the third-prize holder, said in the Committee-room he did not think any of the blooms were made up; at the same moment, correcting himself, he said, "Yes, I am only suspicious of one bloom, and I don't know if this is made up." This shows how very little the thing had been looked into, as almost everyone present expressed a doubt. Even the Secretary when he took out the first bloom, shook it and said, "That's all right." "Oh! uncup it." Still it is all right. "Now remove that wool and wire." Still all right. "Now get hold of the top and bottom and draw gently;" but he took hold of the bottom and pushed up the stem, when to the astonishment of all present the top bloom went up like a parasol, leaving the second bloom in his hand, which caused great excitement, and a general cry of "Who would have believed it?" A hole was made in the centre of the bottom bloom and the stem of the top one drawn through it to appear as one. After several of the blooms had thus been dealt with I took out my pocket book and read my notes in the presence of everyone, and before the examination was over the remark was that my words had come true.

I was truly sorry for the officials of the Society. The Secretary said he would not on any account such a thing had taken place, as people would think that all Liverpool had taken part in it to get up the blooms to defeat those from a distance; but I hope and trust the supporters of the Society will take a better view of it, and display their determination to support the Society by contributing more largely to the funds, and enable them to offer better prizes, and to enforce justice by making a practice of uncupping a number of the blooms, so that merit may be given to whom merit is due. I most certainly blame the Judges very much for not having been more careful in making the awards and satisfying themselves that they were genuine blooms, and it is much to be hoped that such unprincipled practices will never again be adopted.

On referring to the rules it was found that Mr. Roberts had forfeited all claim to his prize money, and also could never again be allowed to compete in Liverpool. This is a truthful report of the whole affair, by one who was styled in the *Liverpool Daily Mercury* "a boasting man from the south." I suppose it was because he detected the fraud.—J. OLLERHEAD, *The Gardens, Wimbledon House, S.W.*

NOTES AND GLEANINGS.

IN a recent importation of Orchids Mr. Bull has had the good fortune to receive several plants of a PURE WHITE VARIETY of *LÆLIA ANCEPS*. One plant is now flowering, the flower being singularly chaste and beautiful. It has the same long bracts and broad petals of *L. anceps*, and every part of the flower, except a yellow blotch in the throat, is pure spotless white. The plant is dissimilar also in character from the species, having shorter pseudo-bulbs and leaves, the former being very pale in colour and not tinged as in *L. anceps*. The new acquisition will probably be named *Lælia anceps alba*—a simple expressive name appropriate to a flower so simply and charmingly attractive. This new *Lælia*, as Mr. Bull suggests, holds the same relative position to the species as does *Lapageria alba* to *L. rosea*, or *Cattleya Skinneri alba* to its species. The white *Lælia* is certainly equally distinct, and cannot fail to become highly popular.

—THE fixture of the first Committee Meeting of the ROYAL HORTICULTURAL SOCIETY was stated on page 408 as January 4th; it should have been January 14th. It is the more necessary to make this correction, as we perceive the error has been also circulated by some of our contemporaries.

—WE are informed that the fifth annual Exhibition of the RICHMOND HORTICULTURAL SOCIETY has been fixed for Thursday, June 26th, 1879, and a Chrysanthemum show is contemplated to be held in the autumn of next year.

—AT the next meeting of the Fruit and Floral Committees, South Kensington, Messrs. Charles Lee & Son will exhibit a very interesting collection of HARDY EVERGREEN and VARIEGATED-LEAVED PLANTS. Mr. Gilbert, Burghley, will again exhibit his new double Primulas, and Mr. Gardiner will send a large collection of Apples from Eaitington Park.

—MR. GEORGE HUMPHRIES, Kingston Langley, Chippenham, gives his experience in reply to "W. H. J." on STRIKING BRIAR CUTTINGS. In November he selects well-ripened shoots of Briars from the hedges, and makes them in the same way that Manetti cuttings are made, and plants them 9 inches apart in rows 2 feet asunder. In the following August he has good stocks for budding, and then inserts the buds on the main stem as near the base as possible.

—WE have received the schedules of the spring Shows of the ROYAL BOTANIC SOCIETY. In the first Show, March 26th, 1879, we observe that the class for six stove or greenhouse forced herbaceous is withdrawn, the exhibits in the class not having been satisfactory, and a class is added for Amaryllises. The only alteration in the second show, April 23rd, is the withdrawal of the amateurs' Auricula class of six plants, a slight addition being made to the prizes in the open class of twelve plants. With the exceptions named the arrangements of the schedules and the prizes offered are practically the same as last year.

—WE record with extreme regret the DEATH OF MRS BASS, wife of Mr. Abram Bass, which occurred at Moat Bank, Burton-on-Trent, on the 26th ult. in her sixty-third year. The gardens at Moat Bank, and the fine orchard house there, were described on page 116, vol. xxx. of this Journal, and from that description we extract the following pertaining to Mrs. Bass:—"All the trees in this house are in the first condition of health and fruitfulness, and they are in the sole charge of Mr. and Mrs. Bass, who train, prune, pinch, and water them. The orchard house is their recreation ground—their 'hobby'; their pleasure is to grow and give—a delightful, wholesome, healthy life. Mrs. Bass is a pomologist who can hold refreshing converse on the subject which she practises so successfully. The modes of pruning and pinching of the fruit of English and continental growers are familiar to her 'as a tale of love.' Her work is indeed a work of love—love guided by skill and crowned with success." We never met a lady possessing a greater technical and practical knowledge of fruits, nor one who more completely adorned a home and garden than her whose death is fittingly recorded in these pages, which in life afforded her so much delight.

—THE annual rainfall of Cyprus according to the Scottish Meteorological Society is about 14 inches, nearly the whole of which falls from November to April, notably in November and December; no rain falls in June, July, and August, and but in trifling amounts occurring rarely in May and September. There are thus practically five rainless months in the year in Cyprus. Comparing it with the coast of Syria opposite its winters are milder and its summers cooler. The coldest month is February, with a mean temperature of 52° 8', being about equal to that of London in the middle of May, and that the mean temperature of August is nearly as high as that of July, both being about 81°, which is approximately the summer temperature of Algiers, Alexandria, Athens, and Constantinople. During these four years the highest recorded temperature of any of the months was 96°, except June, 1869, when from the 21st to the 24th the mean temperature at Alethriko, three miles and a half inland from Larnaka, reached 95° 5', being about the average summer temperature of the Punjab, rising on one of these days to a maximum of 103°. On the same day the temperature rose to 100° at Larnaka, and to 103° 5' at Jerusalem, 2500 feet above the sea, the period being characterised as one of unprecedented heat and drought over the whole of the regions bordering on the Levant.—(Nature.)

—RECOGNISING the importance of VEGETABLE AND FRUIT CULTURE the Council of the Royal Agricultural Society have announced their intention of awarding prizes in connection with their great Exhibition, to be held in London next year, for market gardens. Prizes of £50, £25, and £10 are provided for market gardens not exceeding fifty acres in extent within a radius of twenty miles from Charing Cross,

similar amounts being offered for garden farms exceeding fifty acres. Prizes of the same amounts are also provided for farms not exceeding one hundred acres in extent where garden and agricultural crops are combined, situated within a radius of within fifty miles of the Mansion House. This is a step in the right direction, for no class of cultivators merit official recognition more than those who supply the great markets with wholesome and necessary food of the nature indicated.

— THE schedule of the NEWCASTLE-UPON-TYNE SPRING SHOW (April 9th and 10th) has reached us. It is comprehensive and well arranged in three divisions :—1, open to all ; 2, open to all except nurserymen ; 3, open to amateurs (not professional gardeners) only. There are no entrance fees in any division, and the prizes throughout the schedule are liberal without being extravagant. We note a great improvement in the wording of the chief class for Hyacinths, in which £11 is offered in four prizes. Last year the condition was "thirty-six Hyacinths, three bulbs in a 7-inch pot." This year the prizes are for "twenty-four Hyacinths, singly in pots, not less than twelve varieties." Tulips last year were shown six in a pot ; this year the number is reduced to three bulbs. There is a great increase in the Auricula classes. Last year there was only one ; this year there are five. The total number of classes is ninety-two, and the amount offered in prizes exceeds £174. A great and good show is anticipated. Messrs. Taylor and French remain the Honorary Secretaries, and Mr. Gillespie the acting Secretary, and a more competent trio it would be difficult to find.

— IN the report of Messrs. Sutton & Sons' Root Show CAPSICUM PRINCE OF WALES was incidentally mentioned as contributing to the attractive appearance of the tables. The plants as grown by Mr. Wildsmith demand more particular notice. They were dwarf standards, having stems about 18 inches in height, and compactly-formed heads about 9 inches to a foot in diameter. They were heavily laden with bright scarlet fruit, which was set off to advantage by healthy green foliage. The plants were in 6-inch pots, and had, we believe, been plunged in a warm position in the open air for some time during the summer. Plants so short-jointed and heavily fruited as these were could not have been produced under glass in a heated structure. They were admirably grown and remarkably ornamental.

— WE are glad to learn that the NATIONAL CARNATION AND PICOTEE SOCIETY and the NATIONAL AURICULA SOCIETY are in a flourishing state, the Treasurer of the former having a balance in hand of £7 4s. 1d., and of the latter £13 4s. 7d. The Auricula Show, we believe, is fixed for April 22nd, and the Carnation and Picotee Show on July 22nd, both shows to be held in the Royal Horticultural Society's Gardens at South Kensington. We presume the above information is correct, as it has not been officially communicated to us.

— OUR correspondent "W. J. M." informs us that from 12° to 16° of frost have been recently registered in Tipperary, and that Chrysanthemums in an unheated orchard house have been despoiled of their beauty. Much injury has also been done to Cinerarias and bedding plants owing to the suddenness and unusual severity of the frost so early in the season.

— WE have received from Mr. Christison, gardener to R. O. White, Esq., The Priory, Lewisham, a very fine truss of *LAPAGERIA ROSEA* containing eleven richly coloured flowers. It was cut from a plant planted out under one of the stages in a span-roofed greenhouse, and trained to a trellis upon the roof. We have seen equally fine, even finer, trusses, yet the one sent is noteworthy and very beautiful. We noticed a truss of the charming white-flowering variety in Messrs. Veitch's nursery a short time ago with twelve flowers. These are two of the most valuable plants which Messrs. Veitch have ever introduced into this country.

— THE gardener above mentioned also sends us a flower of *ONCIDIUM UNGULATUM* with the following note :—"This beautiful Orchid is not grown nearly so much as it ought to be, considering the time of year it flowers and the length of time the flowers last after opening. The flower which I enclose for your inspection has been open over five weeks. The plant was imported last spring, it started into growth early, made a fine pseudo-bulb during the summer, and early in September began throwing up the flower spike, which at the present time has attained the length of 5 feet 4 inches, with four side branches from the spike about 14 to 16 inches

in length each. It has not finished growing yet, as there are several flowers to open." The labellum is a quarter of an inch in diameter ; colour bright primrose, the sepals being pale chestnut marbled with greenish white. It has a delicate primrose perfume.

— WHEN visiting the nurseries of MESSRS. SUTTON AND SONS AT READING recently we observed a new *Primula* of striking colour and undoubted merit named Ruby King. The flowers are very large, admirably formed, and of great substance. They are also quite distinct in colour and very rich—a glowing purplish crimson with orange centre. The plant is of dwarf yet robust habit, and the flower trusses are produced just above, almost resting on, ample dark green foliage. Amongst a very fine collection of superior varieties of *Primulas* Ruby King arrested attention. It is a great acquisition, and a valuable addition to an important family of plants.

— MR. BROTHERSTON communicates the following note on *JULIE LAGRAVIERE CHRYSANTHEMUM* :—"It is the most serviceable plant we have for supplying dark-coloured flowers at this season. We have many plants of this variety, each producing dozens of deep crimson blooms, which last good in rooms for nine or ten days, and then do service amongst the servants. How are they grown ? Merely struck late in a mild heat, hardened off in the cutting pots, and planted from thence in April into a border in the kitchen garden. Staking to secure them from breakage by winds is all the attention bestowed during summer. They are lifted with other serviceable varieties in October, and again planted out in a Peach house, and at the foot of walls wherever there is space ; and there for three months, the dearest in the year, they supply their lovely flowers in galore."

MANETTI VERSUS SEEDLING BRIAR.

WHILE the above subject is being discussed it would be well if the following point could be settled : When budded and bearing a Rose tree, how is the one stock to be distinguished from the other ?

A short time since I saw Roses upon seedling Briar offered for sale in the Journal, and bought a quantity of them. When they came to hand I sent some of them to a gentleman who is one of your contributors, and who has cultivated Roses for many years, and he pronounced them to be upon Manettis, not seedling Briars. On writing to the seller he denied this, saying he had not had fifty Manetti Roses in his possession, and affirming that his Roses were all worked upon seedling Briars or rooted Briar cuttings.

There are thus two points at issue which might, I think, profitably be discussed, and upon which I should like to be informed—viz., how can a Manetti-stocked Rose be distinguished from one on seedling Briar ? and is a Rose upon a rooted Briar cutting as valuable as one upon a seedling Briar ?

—A PERPLEXED ONE.

HEADINGTON HILL HALL,

THE SEAT OF G. H. MORRELL, ESQ.

NEAR to the good city of Oxford is Headington Hill Hall, a stately building massive and rich in architectural embellishments. It occupies a commanding position in the centre of gardens tasteful in design and exceedingly well kept. The well-timbered grounds are traversed by carriage drives from the two ornamental entrances termed the lower and upper lodges, erected at different points in the boundary walls, the open ironwork of the gates affording the passer-by something more than a glimpse of the ornate interior. Although worthy of admiration for itself alone, Headington Hill Hall may also be regarded as a noble adjunct to the stately old city, which abounds with many grand structures which by their quiet dignity impress the mind so forcibly as to render it somewhat fastidious and not easily pleased with less imposing sights.

It was with some such impressions that I went to inspect Mr. Morrell's gardens, and so was somewhat more than usually disposed to be severely critical. I was pleased, as there was ample reason to be, for I found much to admire and little if anything to condemn. From the lower or Oxford lodge a boldly sweeping carriage drive leads to the dressed grounds and the house, as represented in the engraving (fig. 68). A pleasing expanse of lawn, well broken but not crowded with shrub groups and trees, ascends gently to terraces on the south and west fronts, the ground from thence rising abruptly—a steep Laurel-clad bank—to a much higher level, which imparts an

agreeable character to the grounds, and affords valuable shelter to the terrace gardens.

The south or Holly terrace is semicircular in outline. It is entirely filled with flower beds on turf of a novel and pleasing design, simple yet elegant. The outer bed describes a bold semicircle marking the outline of the terrace sweeping round into curved ends which join the inner lines—an alternating series of flat curves and small semicircles projecting inwards, and each containing a specimen Holly, of which there are six. This large bed is the key of the design, which in reality contains only two other large beds with half a dozen intervening circles. In the centre is a Pampas Grass, and at either end a Wellingtonia—a trifle formal, but necessarily so, yet ample relief is afforded by the lawn sloping gently down among shrubs and fine old Elms. Through these an occasional church spire comes into view with an undulating range of hills in the far distance. The whole of the beds were planted with Viola

cornuta in variety, all flourishing and full of bloom, affording a charming display of this popular flower. An air of elegance pervaded this part of the garden in a manner not at all common to terraces, which are generally too full of straight lines and harsh angles to harmonise with surrounding objects.

The west front has a garden of more formal tone—a series of abrupt slopes and levels—yet nevertheless in perfect keeping with the steep bank on the upper side of it. A fountain and stone basin occupy the centre, and the numerous beds contained pretty and well-wrought devices in carpet bedding. From the top of the high bank, to which we ascend by a flight of steps, the view over Oxford is very fine. A lawn with enclosing shrub borders sweeps pleasantly onwards to the upper entrance lodge, the carriage drive being remarkable for its easy well-formed curves, and the skilful way in which the lawn is made to ascend from it to rising ground on either hand. An avenue of Cedrus Deodara, [through which this

Fig. 68.—HEADINGTON HILL HALL.

drive runs, is in a flourishing condition, and will one day be a fine feature. It and the numerous other Conifers and shrubs were planted by Mr. W. H. Baxter, Curator of the Oxford Botanic Gardens, who laid out Mr. Morrell's gardens, and who has published a valuable descriptive list of nearly two hundred sorts of the trees and shrubs which adorn the grounds.

The kitchen garden and glass houses have hitherto been separated from the pleasure grounds by the public road which intersects the estate. An elegant bridge, however, has lately been constructed, so that in future the principal path to the kitchen garden will run over this bridge and through extensive new pleasure grounds in course of formation. It will thus be seen that improvements of an important character are in progress; and although already so worthy to be termed a fine place, much remains to be done before the whole is finished and thoroughly connected.

Some four acres of rich light soil constitute the kitchen garden, yielding an ample supply of vegetables with thriving fruit trees mostly cone-shaped, and forming avenues along the paths. Some lofty vineries contained good crops, the Grapes being well coloured, large in bunch and berry, and the growth healthy and vigorous. Mr. Phillips the gardener is evidently a master in the culture of Grapes. A lot of young Muscats had magnificent canes, and were from cuttings made in Febru-

ary, 1877, the Vines being rooted and planted out in the border in June that year, cut back in the autumn, and making growth this year, that will yield a noble crop of fruit next season. Peaches were also abundant and fine under glass; so, too, were Strawberries in pots, the sort being President, high feeding being practised, and only eight berries being left to swell on each plant—a much more sensible plan than that of leaving a host of little berries hardly any of which prove fit for table.

The interior of a house devoted to the culture of stove plants presented an appearance totally different to the usual stereotyped arrangement of stages and pits. From end to end of the house is a serpentine path, describing a series of graceful curves around the base of mounds of earth alternating from back to front. Nothing could be better. It was a veritable tropical flower garden, the mounds forming the beds in which pots may be plunged; or, better still, the plants turned out into the soil, and the roots let ramble so as to induce a much more luxuriant growth than the confined space of a pot ever can afford. Then, too, what a charming fringe of exotic Mosses, Ferns, and tropical trailers may be had on either side of the path.

Good taste prevails here, and suggests that the remedy for formality is in our own hands. By such an arrangement as

this house affords we may impart an air of elegance, and at the same time avoid the considerable outlay which the construction of pit, walls, and staging necessarily involves.—
EDWARD LUCKHURST.

OUR BORDER FLOWERS—MEADOW RUE.

WHILE so much interest is taken in plants for outdoor decorative purposes, especially choice border plants, I have thought it somewhat surprising that the Meadow Rues have so long escaped attention. Perhaps these plants may be thought too common for choice positions; be it so, yet nevertheless they have their charms. There is something pleasing, and graceful too, in their Fern-like appearance when associated with other plants of more brilliant hues. My idea is that no collection of border flowers approaches perfection without an admixture of Meadow Rues. They are a numerous and widely distributed family, and ought no longer to remain in the background, but should find their way to every rockery and border of any pretensions where such plants are cultivated. They vary in stature from a few inches in height to as many feet. The taller-growing kinds are very well adapted to large borders and open spaces in the shrubbery and other semi-wild places. The Columbine-leaved Meadow Rue (*Thalictrum aquilegifolium*) is a grand old border plant which lasts a long time in bloom, but is seldom met with in cultivation. *T. flavum* is of somewhat deeper colour; a very pretty border flower, the more interesting by its being one of our own. *T. glaucum*, *elatum*, *dioicum*, and others might be named that are worthy of the attention of cultivators. *Thalictrum anemonoides flore-pleno* is a very choice plant; it loves moisture, but not stagnant soil, and is all the better for having partial shade. It is well adapted for the rockery. *Thalictrum minus* is the most interesting of the family. Some day it may be seen doing good service as an edging plant; it needs only to be seen in that position, and then interest will be taken in its cultivation. It is useful, too, as a pot plant, having the appearance of an *Adiantum*.

Thalictrums thrive in ordinary garden soil, but all the better if a sprinkling of lime rubbish and well-decomposed vegetable matter and coarse grit are mixed in the compost. They are best increased by division after flowering; they may also be increased by seed sown in the spring in light sandy soil in a shaded situation. When the seedlings are large enough plant them out where they are intended to remain; when established they last many years.—VERITAS.

WINTERING PLANTS—DAMPING-OFF.

THE damping-off to which plants and flowers are so liable during the winter months is simply the result of injudicious treatment. Such popular plants as the Chinese Primula and the Cyclamen may be taken as illustrative subjects. These two plants are considered by many who cultivate them as difficult to manage, and as requiring special care in the matter of watering, more particularly throughout the winter months. It is during the close of the year, when the cold of winter is in some degree presented to us, that decay is first noticed on these plants, and when precautionary measures are first considered necessary and acted on.

I have had my share of trouble with those plants during the winter, having had to deplore specimens of the former which would, notwithstanding all care, sever connections 'twixt top and root, and in the case of the latter have had leaf after leaf and flower stalk after flower stalk decay, leaving the parent corm crownless. I have also enjoyed a good share of success in growing the plants referred to. I am in a position, therefore, not only to sympathise with any who are in difficulty but can point out a remedy for the damping.

But what is the cause of damping, and what the remedy? Some conclude that potting the plants too low is a primary cause of the evil complained of, and that watering induces damping-off, and consequently that keeping the plants with the base of their stems elevated sufficiently above the soil so as to secure them from contact with water is the remedy. Others consider attention to keeping the roots in a half-dry medium the best preventive, whilst a moist condition of the soil is a sure cause of the affection. Though I am not prepared to say these points of culture may not be in some degree good, they yet neither suggest the real cause of the plants damping off nor afford a true remedy.

Both Primulas and Cyclamens are here potted low, are kept moist at the roots, and yet the plants do not damp off. The

very simple means taken to secure success is to treat them throughout the winter as growing plants from countries favoured with a warmer climate than that of a cold pit. Unless the plants are kept in a growing condition with sufficient heat, plenty of light, and no stint of water, no matter how much care may in other respects be taken, the best results must be unattainable in their cultivation.

The particular degree of temperature must be left to circumstances, as I find the kind of structure the plants are grown in determines this to a great extent. In a pit where they can be placed with their heads 9 inches from the glass a minimum of 50° and a maximum of 55° will be sufficient. In a structure where the conditions with regard to light and air are not so good a higher temperature is necessary. Under such conditions the roots are preserved in a state of continued activity throughout the winter, the assimilating powers of the leaves are not interfered with, and as a consequence the plants continue to thrive.

The same general remarks apply to any plants wanted to flower during the winter season. *Bouvardias*, for instance, in a too low temperature lose both foliage and flowers, whilst in such a temperature as just quoted the plants thrive perfectly. *Geraniums*, *Abutilons*, *Heliotropes*, *Callas*, and other plants which will do well out of doors till late in the season, some of them even being proof against a few degrees of frost, all require a growing temperature to induce them to flower during winter.

Precisely the same remarks apply to bedding plants or others which are kept through the winter merely for stock. Unless they are kept in a somewhat active state of growth it is impossible to winter them with the same degree of success, either in regard to the quantity kept alive or the state of the plants for propagating purposes in spring. Of course there are plants which cannot be kept too cool during winter. *Cinerarias* and herbaceous *Calceolarias* may be mentioned as instances of this, *Pansies* and shrubby *Calceolarias* also; but in order to winter or grow these with the greatest amount of success moisture at root and plenty of light are just as much required as in the case of those plants which require heat.

The only safe practice with regard to plants which make growth or flower during winter is to keep them "moving." Stagnation results in decay and death.—R. P. BROTHERSTON, *Tynninghame*.

WORK FOR THE WEEK.

FLOWER GARDEN.

BEYOND the constant work of sweeping, rolling, &c., that the season entails little remains to be done in this department, provided the work as treated of in former calendars has been well advanced. There is little to attract attention in the herbaceous borders now, yet there is considerable risk at this time of year in digging those borders, especially where the positions of all plants and bulbs are not indicated by stout hardwood pegs placed near them. In the case of bulbs and such plants as are well known this method of indication answers very well, yet it adds much to the study and interest of plants to have them properly named. See, therefore, that any pegs or labels becoming rotten or have the names illegible be renewed. The borders should be made neat, loosening the surface if it has become very firm, and giving at a convenient opportunity a top-dressing of decayed manure or leaf soil, which will both enrich the soil and form a protection for the plants against the severity of the weather. Slugs are often troublesome; a sprinkling of quicklime or soot prior to the surface-dressing will do much to check their depredations. Rats and mice, the latter particularly, commit much mischief in a short time among bulbs when once they find them out; hence the necessity of keeping a sharp look-out and promptly trapping the marauders. We find small steel traps baited with cheese prompt killers.

Protecting Plants.—*Pyrethrums*, *Delphiniums*, &c., liable to have the crowns preyed upon by slugs should have the soil taken out about them, a sprinkling of quicklime or soot given, and the openings filled up with sifted ashes. Before severe weather sets in plants of doubtful hardiness should receive the needful protection. A few leaves with bracken over them placed around the crowns, and a few Laurel or evergreen branches thrust into the ground to keep them from blowing about, will afford sufficient protection to such plants as *Bambusas*, *Aralias*, *Phoriums*, *Chamaerops Fortunei*, *Gynierum argenteum*, &c. Plants on walls of doubtful hardiness, such as *Edwardsias*, *Ceanothus*, *Magnolias*, *Myrtles*, &c., are best protected by mats in severe weather, double mats being usually sufficient protection from the severest frosts. Beds of *Roses* should be well protected with litter, which is generally sufficient for *Perpetuals*, but *Teas* and *Chinas* should have some evergreen branches stuck amongst them in severe weather; but with the roots protected it is astonishing what an amount of

cold plants will bear. In heavy soils the Teas may be lifted, potted, and plunged in ashes in a cold pit, where they can have protection in severe weather, planting them out the following April. Belladonna Lilies should have some partially decayed leaves placed over and around the crowns, as the bulbs have a tendency to come near the surface, and if not protected are injured or killed by frost. With good drainage, a warm situation, and protection from frost these are the finest of autumn flowers, flowering splendidly. Crinums and similar plants are the better of a protection of leaves, with a few evergreen branches to keep them in position. Lobelias of the herbaceous class may have the roots lifted, potted, and wintered in a cold pit, or have a mulch over the roots of partially decayed leaves. Carnations, &c., are much preyed upon by slugs: dusting soot about and over the plants will keep the pests in check. Plants in pots in frames should have air whenever the weather is favourable, with no more water than to keep the foliage fresh, affording the protection of mats over the lights in severe weather.

HARDY FRUIT GARDEN.

The pruning and nailing or tying of Cherry, Pear, and Plum trees against walls as well as espaliers should be proceeded with whenever the weather is favourable; also the pruning, &c., of Apricot, Peach, and Nectarine trees, which is generally deferred until early spring or until danger from severe frost is past. Unless the wood be unripe there is no danger whatever to be apprehended from frost; indeed, with the wood in good condition we prefer to prune in early winter, when there is less sap in the growths, than in early spring when the sap is active from the swelling buds. But whether the trees are pruned or not now they should be unnailed or cut loose, the branches and such shoots as require it being merely secured to the wall or wires loosely so as to prevent scrubbing by winds.

The Raspberry.—This is one of the most useful fruits. The canes of the current year should be thinned out, leaving from four to six of the strongest to each stool, selecting, of course, the best placed, and securing them to stakes. We use tarred string for this purpose, and then cut back the canes to the height required; but in some instances, as that of very strong unripe canes and in cold localities, shortening may be deferred until spring. Various modes are adopted of cultivating the Raspberry, all of which, it may be said, have under certain circumstances their respective advantages. All agree in planting in deeply trenched highly manured ground. Some plant the canes in lines 6 feet apart and 4 feet from plant to plant, but in poor soils less distance may be allowed. Some secure the canes to stout stakes about 4 to 5 feet in height, cutting the canes back so as to correspond with the stakes. Some plant or tie the canes together, dispensing with the stakes. Some tie the ends of one set of canes to the other or next set of canes in the line, so as to form an arch of the bearing canes with or without a stake in the centre of the arched canes; others secure the canes to rails in the form of espaliers; and others, again, merely thin out the canes and shorten them, running a line of string or wire around the plantation to support the outside canes. Any of the above plans answer. Manure liberally, pointing it in lightly near the stools deeper in the spaces between the lines. In light soils surface-digging is not desirable.

Fig trees in the open air if left unprotected suffer in a severe winter, sometimes being seriously if not fatally injured. Trees trained to walls may be unfastened, the branches tied up in bundles, which should be encased in clean straw or dry fern and made secure with mats. Some leave the trees on the walls and thatch them with straw or fern and cover with mats: the bundle plan is preferable. The border up to the stems should be well mulched with partially decayed manure or litter. The spaces between the rows and plants of Strawberries should, if not already done, have a mulch of partially decayed manure, employing it rather littery for such varieties as British Queen, that are the better for having slight protection.

FRUIT HOUSES.

Pines.—Considerable skill and skill are required to maintain with limited means a successional supply of ripe Pine Apples throughout the year. The cultivator with his hundreds of successions may do so readily enough, but the unenviable gardener with his tens or twenties is often at his wit's end to act so as to have fruit at the right time. Where a supply of ripe fruit is required in May and June, and plants are not showing fruit, it will be desirable to select from the plants started last March, which have completed a stout growth and are now in a state of rest, such as show the best indications of starting into fruit when subjected to a higher temperature both at the roots and atmosphere. If the plants may not be accommodated in a structure to themselves they should have a light position in the house where the fruiterers are swelling off. It is not wise to start more plants at this season than is absolutely necessary, as the fruit will come up more readily a month hence and be much stronger. Continue former instructions as to temperature, &c., but in very severe weather a fall of a few degrees in the temperature is preferable to extra sharp firing, and wherever practicable a covering placed on the glass at such times will be desirable, being a saving of fuel and better for the health of the plants.

Cucumbers.—The winter fruiterers will be showing plenty of fruit. Unless the plants are extra strong two-thirds of the fruit should be removed, removing also the male blossoms and tendrils, also any superfluous shoots and bad leaves; but do not stop the growing points overmuch for the next few weeks, affording water moderately—a supply twice a week will suffice. Plants, of course, growing in pots or boxes will require water oftener, with liquid manure occasionally. A night temperature of 70° to 65° in severe weather, 60° as a minimum, 70° to 75° by day, advancing to 80° or 85° with sun, will be suitable. The plants will require moderate earthing from time to time, taking care that the soil has previously been warmed; press it tolerably firm but not very hard. The bottom heat should be kept steady at about 80°. Atmospheric moisture will require to be moderate, damping only on bright mornings or early in the afternoon. If a night covering be afforded of mats or frigi domo to the glass it will be highly advantageous, but it must not remain on by day to the exclusion of light, every ray of which the plants must have. Remove old foliage and exhausted growths from the autumn fruiterers, but do not overstop the growing points, avoiding overcrowding and especially overcropping. Fertilise the female blossoms during a continuance of dull sunless weather.

PLANT HOUSES.

Orchids.—This being the most inactive period in the growth of these plants, employ no more fire heat than is necessary to keep the temperature at 65° by day, 60° or a little less by night for the East India house; 55° to 60° by day and 50° at night in the Mexican house; and the cool house 50° by day and 45° at night, allowing a few degrees rise in each case from sun heat. Very little air is now required, but no opportunity should be lost of sweetening the atmosphere. Nothing contributes more to this than sponging the inside of the glass once a week, which secures to the plants all the light possible. Attention must be paid to the atmosphere, sprinkling water over the shelves and paths every morning. Sphagnum and roots outside the pots or baskets will require frequent dampings, especially such plants as *Aërides*, *Phalænopsis*, *Saccolabiums*, and *Vandas*. Although *Cattleyas* and *Lælias* root freely at this time, they require very little water at the roots. The peat employed for potting them should be of a description to allow the water to pass away freely. *Cypripediums* and *Cymbidium*s require a good supply of water at the roots. Any *Dendrobium*s required to be retarded for flowering until May should be placed in a greenhouse temperature. Very little water—probably none—will be required until they begin to grow, when they should be removed to a warm house, as any check they may receive at that stage is followed by abortion or stunted growth. *Odontoglossums* should never be allowed to become dry. They delight in a cool damp atmosphere. Afford a light sprinkling overhead on fine mornings; though these plants like moisture they are impatient of drip. Woodlice, cockroaches, and crickets are sometimes troublesome, having a particular relish for the flower spikes. Poison should be kept about the house, and a keen look-out kept after dark with a lantern for slugs, potato baits being set for woodlice. A supply of peat should be got in, also sphagnum, picking all the rubbish out of it; and if spread upon a damp floor it will keep fresh for weeks, it being desirable to use it in as fresh a state as possible. Baskets may also be made, everything needed in potting or basketing, the plants being held in readiness for use at the time required.

TRADE CATALOGUES RECEIVED.

William Barron & Sons, Elvaston Nurseries, Borrowash, Derby.—*Trade List of Coniferae, and Descriptive Catalogue of Ornamental Shrubs.*

Robert Mack & Son, Catterick Bridge, Yorkshire.—*Catalogue of General Nursery Stock.*

Richard Dean, Ealing, London, W.—*Catalogue of Hardy Spring Flowers and List of Potatoes.*

Osborn & Sons, Fulham.—*Catalogue of Hardy Trees, Shrubs, &c.* Galloway & Graham, 138, Queen Street, Glasgow.—*Catalogue of Gladioluses.*

Ferdinand Julkes' Successors, Erfurt, and 50, Great Russell Street, London.—*Trade List of Flower and Tree Seeds.*

Louis Van Houtte, The Royal Nursery, Ghent, Belgium.—*Catalogue of Gesneriaceae and other Tuberous-rooted Plants.*

TO CORRESPONDENTS.

** All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense. Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

BOOKS (M. Unwin).—A small manual, "Fruit Gardening for the Many," published at this office, post free 5d., will afford you sound and useful information. *The Journal of Horticulture* is 3s. 9d. per quarter, free by post.

BRIAR CUTTINGS (J. S.).—It is fully late now to insert Briar cuttings, but if the weather continues mild you may try them. Select well-ripened shoots of the current year's growth from the hedgerows. Make the cuttings about a foot in length, carefully removing all the eyes except three or four at the top, and let the base of each cutting be cut transversely and smoothly close under a joint or removed bud. Insert the cuttings firmly about 9 inches apart in rows 2 feet asunder, and draw some soil to them after the manner of earthing Potatoes, only allowing the portion with eyes to be above the soil. When growing freely in August level down the ridges and insert one bud in the side of each rooted Briar as near to the ground as possible. The bark usually parts from the wood freely where it has been covered with soil. We have found the cuttings strike freely when inserted during October and November.

BRITISH WILD FLOWERS (Z. Y. P.).—We publish a work so entitled—plates coloured. Ten volumes are completed, price 23s. 6d. each, each volume containing eighty plates. You can have them at our office. A number is published monthly, price 1s., containing four plates, with full descriptions.

TREES FOR ESPALIERS (Orchard).—Green Gage and Purple Gage Plums; Early Harvest, Kerry Pippin, Gravenstein, and Blenheim Pippin Apples; Williams' Bon Chrétien, Fondante d'Automne, Marie Louise, and Winter Nelis Pears. If you mean by tile-planting paving under the stations, that will very much depend on the nature of your soil.

STEAM versus HOT-WATER HEATING (W. M. G.).—Heating by hot water is cheaper, safer, and healthier than heating by steam. Cheaper, because no appreciable amount of steam is produced until the water is heated to 212°, and consequently a great amount of fuel is expended before steam is produced, which otherwise would have been turned to valuable account if the hot-water mode of heating were adopted; safer, because no accident can happen with heating by hot water as applied by hot-water engineers, but there is no absolute immunity from accident in the case of heating by steam; healthier, because a highly heated surface of 212° is far more pernicious to human beings or plants than a surface less highly heated. In heating by steam the maximum temperature must always be produced let the weather be what it may; but in the case of hot water the surface of the pipes can be heated to any degree required according to circumstances. If a sufficient amount of piping is provided the requisite amount of heat can usually be produced in churches and forcing houses without the water boiling at all. Thus the saving of fuel in comparison with heating by steam is incontestable.

BOILER DRAUGHT (S. O. J.).—Six inches is not too wide for the side flues of a saddle boiler, but the depth of such flues is often considerable with a view to expose as much of the boiler surface to the action of the heat passing along the flues. Nine inches depth of flue is ample. Too much is expected from side and top flues. We can only attribute the want of draught in your apparatus to some undue contraction in the flues, or depressions with probably too contracted an ashpit, air not being supplied in quantity to maintain rapid combustion.

SOWING LILICUM AURUM SEED (W. M.).—The seed ripens perfectly well in this country, and should now be sown in pots or pans well drained, employing turfy loam and leaf soil or peat in equal proportions, with about a sixth of sand. The seeds should be sown rather thinly and be covered about a quarter of an inch deep with fine soil, placing the pots in a greenhouse and keeping the soil regularly moist. The plants will flower about the third year if they are well cultivated.

EUCHARIS AMAZONICA (Idem).—The plants may be had in flower at any period of the year, it being necessary to secure a good growth, and when that is complete to place the plants in a house with a temperature of 50° to 55°, affording water only to prevent flagging. With from six to eight weeks of cool treatment they may be had in flower in about four to six weeks afterwards by placing them in a brisk moist heat of 65° to 70° at night and 70° to 75° by day, and more certainly with bottom heat of 80° to 85°. The plants do best under rather than over-potted, but if large plants are wanted they may be shifted about once a year, and preferably early in the year. The "Cottage Gardener's Dictionary" is 6s. 6d., post free 7s. 3d.

FRUIT TREES ON A WOODEN FENCE (Amateur).—If the gas tar is thoroughly absorbed into the boards it will do the trees no harm; and although it will become very hot on bright days till covered with growth, yet afterwards the foliage will prevent that, and therefore a change of colour is uncalled for.

DISSOLVED BONES FOR GARDEN CROPS (Idem).—Bones dissolved in sulphuric acid form superphosphate of lime—a most valuable manure, extremely soluble, and therefore soon taken up by plants. It may be applied as a top-dressing to permanent crops, such as Strawberries and Asparagus, at the rate of 10 lbs. to a square perch, or about 14 cwt. to an acre, early in spring, and also sown broadcast and worked-in with hoes among Onions, Turnips, Cabbages, Lettuces, and in fact all garden crops.

CULTURE OF PHAIUS (Rus).—These are terrestrial Orchids, all of easy culture. Pot them in spring, just before growth commences, in well-drained pots in soil consisting of equal parts of fibrous peat, turfy loam, old hotbed manure, and silver sand, taking care not to elevate the plants on a mound, but to keep the soil level and well below the rim. Place them in a night temperature of 65°, rising to 70° by day, and increasing to 75° and 80° as the days lengthen. Water them well during growth, and afterwards remove them to a cool house till October, giving very little water. In November they again require a lively temperature and an increasing supply of water, by which means they may be had in flower towards the end of the year.

FORCING WHITE LILAC (Idem).—The Lilacs sold in Paris in winter are cultivated in pots plunged in the open ground and also planted out in beds, these latter having the roots cut round with a spade about the end of August to induce a free formation of flower buds and to facilitate the removal of the shrubs to the forcing pit, where they are again plunged or planted in the bed. The temperature, cool at first, soon rises as the buds sprout till it reaches a maximum of about 80°. The branches are frequently syringed and the roots well watered with tepid water. The most curious part of the business is the fact that the glass remains covered with mats of straw, termed *paillassons*, day and night to exclude light and blanch the flowers.

SEEDLING BRIARS (Tyro).—Seedling Briars are preferred to Briar cuttings

because of the greater vigour which they possess, in common with all other seedlings, over cuttings.

PROPAGATION OF HOLLIES (H. H.).—Hollies, both green and variegated, may be raised from cuttings made in October and inserted in sand under handlights or bellglasses. Green Hollies, however, are usually raised from seed gathered early in winter and buried in sand till March, when it is taken up and sown in drills on any spare border. The seedlings are transplanted the first or second winter afterwards as they become large enough.

BREAKING-UP GRASS LAND FOR POTATOES (J. T.).—The turf should be pared thinly and burnt, or you will run much risk of having the crop spoilt by wireworms. It would undoubtedly be best to trench the land. That, however, is an expensive operation, and we have obtained excellent crops of Potatoes by deep ploughing, followed by a scarifier or large horse hoe to break up the clods; afterwards spreading and ploughing-in manure at the rate of twenty to fifty cartloads per acre according to the condition of the soil. A similar process to this could of course be done on a small scale with spades or digging forks. For Strawberries the turf should also be burnt and the soil trenched two spits deep, which would be about 16 inches, keeping the subsoil at bottom and working-in plenty of rich manure among both soil and subsoil. Nothing will be gained by planting now, but if you could obtain plants in March they would become thoroughly strong and well established for another season. Vicomtesse Héricart de Thury and Sir Charles Napier are excellent sorts for preserving.

PEACHES AND NECTARINES FOR ORCHARD HOUSE (Armiger).—The following are good varieties for your purpose. *Peaches*: Early Beatrice, Hale's Early, Dr. Hogg, Grosse Mignonne, Noblesse, Bellegarde, and Osprey. *Nectarines*: Lord Napier, Balgown, Violette Hâtive, Pine Apple, Humboldt, and Victoria. Any of the horticultural builders advertising in our columns would erect you a good orchard house; and those who advertise wirework would supply you with Pea protectors. We do not think the "wire cage" suggested would answer the purpose of protecting the blossoms from frost. We are unable to answer your query respecting Briar stocks, but bast for budding can be obtained from any seedsman or nurseryman.

TEBBS'S FUMIGATOR (A Constant Reader).—It can be had from most nurserymen and seedsman who obtain their supply from Flanagan & Sons, 98, Cheapside, London. The price varies according to the size of the fumigator.

PINE APPLE CULTURE (A Young Gardener).—Buy "The Pine Apple Manual." You can have it free by post if you enclose thirty-two penny postage stamps with your full address.

HEATING FORCING HOUSE (H. S.).—There is no need whatever to have a sharp rise in the pipes: all that is necessary is that the flow pipe gradually rise to a certain point, and the pipes from that point decline. At the highest point should be an air pipe to let out the air, and with the pipes full of water the circulation will be good. A saddle boiler, one of the improved forms and as shallow as possible for your position, would answer perfectly. By having a cistern you could heat the house with return pipes, the cistern being a few feet above the boiler as may be required, and the return pipes from it passing through the house, not taking them below the return opening of the boiler.

FLOWERS FOR GREENHOUSE (Inquirer).—Bulbs in variety would give you the quickest display of flowers. Snowdrops and Crocuses may be potted in clumps from the garden. Hyacinths and Tulips may be cheaply purchased. It is too early to sow seeds of annuals. Wallflowers, Hepaticas, Lilies, Violets, &c., may be potted for early flowering, also Roses and other dwarf shrubs.

NAMES OF FRUIT (Miss Hall).—1 and 2, Golden Pearmain; 3, Court Pendu Plat; 4, Dumelow's Seedling; 6 and 7, Shepherd's Fame. Non-subscribers can exhibit at the shows of the Royal Horticultural Society.

NAMES OF PLANTS (H. L.).—It is a very handsome frond of *Adiantum tenerum*, a fine Maiden-hair Fern, native of the West Indies and tropical America.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

SHEEP FOR THE HOME FARM.

(Continued from page 436.)

THE Shropshire breed of sheep next demands our attention. These sheep are particularly adapted to the western and midland districts, which may be said to be their native home; and as Shropshire and adjoining counties contain numerous home farms, the managers will therefore usually select this breed for profitable feeding and fattening. These sheep may be purchased at from one to two years old as wether sheep early in the summer and fed on the pastures or park land until Michaelmas. By that time upon the most fertile grass land they will have become fat enough for the market without artificial food. In the case of pastures not naturally rich or productive, resort should be had to trough feeding throughout the summer by the use of mangolds and meal in admixture as previously recommended for other stock. Mangolds, however, may not always be available, and particularly where the proportion of arable to pasture on the home farm is small; but other roots and early cabbages cut up and meal added will answer every purpose. Green fodder or grass cut into chaff will do, and be moist enough for the meal to adhere to; and this is most essential, for enormous waste will occur if it is attempted to give artificial food without something to give it substance in a palatable

and economical form. After being fed in this way the ordinary breeds of Shropshire sheep will be fit for sale at Michaelmas; and at the same time they will have consumed food the manurial residue of which will have improved the pastures.

The Shropshire sheep are of varying character, but since the Royal Agricultural Society has acknowledged them as a distinct breed they have assumed a more even appearance. The best type by the award of the Judges are the stock bred and reared by Lord Chesham of Latimers. In fact these sheep almost in kindness of character appear like Southdowns; but we prefer some of the stronger larger breed with speckled face, such as we have often had under hand when officiating as judge at shows where the Shropshires formed a portion of the exhibits, as they make more weight at a given age than the higher-bred and neater stock, and furnish more lean meat in proportion to fat. These sheep give a good fleece of wool, which is appreciated by the manufacturers and forms an important part of the profit accruing to summer feeding. Shropshire sheep are a cross, the original being horned and natives of a locality called Morfe Commen, and were first crossed by Southdowns. After this cross they still retained their roaming habit; but to make them more docile and better adapted to feed the rich pastures in company with fattening bullocks, resort was had to the Leicester cross; and this cross has not only made them more quiet in their habit, but has improved the aptitude to fatten, with a better fleece.

We must now refer to the Oxford downs as being best adapted for feeding upon the mixed arable and grass land farms in the midland counties of Oxford, Bedford, Buckingham, &c. These sheep originated in a cross between the Hampshire down and the Cotswolds, some being further improved by a cross with the Leicesters. This type of sheep was so far improved in the hands of the late Mr. Druce of Ensham and Mr. C. Howard of Bedford, that they have now for a number of years been recognised as a distinct breed by the Royal Agricultural Society; and it must be admitted that for feeding in the home farms in the midland counties there is no stock will yield more profit when fed upon the same plan and under the same circumstances as just related for the management of the Shropshire. As wether sheep they will give greater weights when fed upon the system of early maturity than any of the black or mottled-faced polled sheep, and are generally quoted in the Metropolitan Market in conjunction with Southdowns as fetching the highest price per stone. These sheep are also of a quiet habit, which will enable them to feed with bullocks in the pastures with advantage.

The Leicester breed of sheep will require at our hands especial notice as animals well calculated for the home farms situated in the north midland districts of England. Owing to their quiet and docile temper these sheep are especially adapted for feeding in company with horned cattle. In stocking the grass lands it is customary to put on a bullock and one or two sheep per acre, as the fertility of the pasture may require or be capable of feeding. We have known Hampshire downs used for the purpose, but they continually roam about, treading the food instead of eating it, thus starving themselves and the bullocks also. It is therefore a wise custom to prefer the Leicesters, which eat and lie down similar to their companion bullocks. The Leicesters are very quick to fatten, but they do not give a good proportion of lean meat. It is in consequence a good plan not to make them too fat for general consumption. The most economical plan is to send them to market as soon as they have arrived at the most selling stage of fatness. If any artificial food is given, which is not necessary unless the pastures are very poor, it should be beans or lentils cracked and put in troughs, unless mangolds or other vegetable food is at hand to be mixed with meal as before stated. In this way these sheep may be kept on until they reach a great weight, when the meat will be found to consist of flesh and fat in such proportion as will be appreciated by the consumers.

Gloucestershire with its Cotswold sheep, and with it some adjoining counties, furnish splendid animals of great size and heavy weights, well calculated to furnish the markets of the manufacturing districts, where these large stock find a ready sale. They are a hardy race of sheep, and perhaps suffer less from disease (particularly foot rot) than any breed with which we are acquainted, and are especially adapted for the Cotswold Hills and the western districts, which suffer from a heavy rainfall compared with the eastern or southern counties. They feed quickly when put upon good and liberal keeping, and for early maturity of meat they are exceeded by none, but the flesh is coarse although yielding a fair proportion of lean meat. When selected for feeding upon the home farm it should be in some district similar in soil and climate to which they have been accustomed, and where there is a ready sale for these strong and heavy sheep. The wool, too, being long gives weighty fleeces and forms no inconsiderable portion of the profit of feeding this kind of stock.

The Lincoln sheep are particularly adapted for the fen districts of the county from which they derive their name, also for Cambridgeshire and adjoining counties, where they are greatly valued, particularly for the weight of their fleece, which sometimes is said to yield the principal part of profit in feeding, for tegs of this stock in the spring of the year sell for a long price. The length

of the wool is rather against this stock for feeding off turnips upon the land, as the wool often reaches within a few inches of the ground, and they are principally fed upon the rich grass lands of Lincoln and other counties. The management described for other long-woolled sheep applies in full force to this breed both as to feeding and otherwise.

We will now consider the sheep best suited for feeding on the home farm when it is situated in the vales of Scotland and the English border counties. We have a breed admirably adapted for this purpose in the Cheviots; for although they are, strictly speaking, natives of the mountainous districts, yet they flourish more particularly in the valleys, and when crossed by the Leicesters they have proved very profitable. Considering that they are natives of the hills they are extremely docile compared with the black-faced horned sheep of the mountains. They yield to superior management and folding off upon roots in the enclosed districts; and being of only a moderate size they fetch a good price per stone in the market. Except when crossed with longer-woolled breeds they produce only a moderate weight of wool. As they are, however, the chief stock kept in the northern counties and the best lands of Scotland, we are compelled to believe that they are well suited to the soil and climate of these districts; and as most of the modes of feeding before described will apply to these sheep we shall not here repeat them.

There are various other breeds of sheep which may be kept upon the home farm in certain districts with profit, yet as they assimilate so much to some of the breeds before named, we shall conclude by remarking that good management for one may be considered equally beneficial for the other.

WORK ON THE HOME FARM.

Horse Labour.—The period or seed time for autumn wheat sowing being about over, the question may well be asked if it is desirable to sow wheat after this time whilst the value of that grain in the market is so low? Upon many kind barley soils in good condition where roots have been fed-off by sheep, rather than sow wheat it may be held over for barley in the spring, to be ploughed now and left for the earliest season, by merely scarifying and drilling during the first fine weather in the months of February or March. Fallow ploughing of the land intended for root crops next year should now be pushed on so that it may be concluded before hard frosty weather sets in. Old saintfoin leas and old clover leas intended for oats in the spring may now be ploughed and pressed with advantage, because it will give time for the old sward to decay, and for the land to become stale and mellow before the spring seed time arrives. Some horses and men may now be employed in carting roadside earth, also earth obtained by scouring ditches to a heap to decay, so that it may be ready for future use in placing at the bottom of pigsties, cattle pens, cart horse stables, &c. The farm roads and approaches, together with the rick yards, &c., should now be shovelled over so as to collect everything in the shape of soil, rotten straw, and cattle droppings, not only for the sake of cleanliness but for the value of materials for laying out on pastures. If the pasture land is dry it may be laid out at the time of collecting, and save the expense of heaping and second cartage. The roadside earth, &c., may be laid out also, and spread immediately; it will then prove very beneficial to the grass land, especially if 2 cwt. per acre of guano or nitrate of soda is applied in the spring, because the earthy substances supply the mineral matters required, and the guano and nitrate the ammonia required. This will afford the best and cheapest dressing for the grass land, not only to increase the crop but also to improve the quality of the herbage.

Hand Labour will consist of trenching in the meadows, also cutting the water carriers and the relieving trenches in the irrigated meadows, as the earlier this work is done the more the produce will be benefited, and the earlier the grass will be in the spring, either for feeding or for a hay crop. The action of the water in the irrigated meadows is not only fertilising by the deposits of earthy materials at flood time, but in the winter months when the temperature of the air is very low the temperature of the earth when covered with flowing water is higher, consequently the grass grows much faster than when exposed to the atmosphere. The steam-threshing of corn will be going on where fodder of the Lent corn is required; this will employ some men and women too. We have, however, often saved the expenses of threshing and winnowing by cutting the corn fresh out of the rick, straw and all together into chaff. The only question to be arranged and considered is the quantity of corn contained in the chaff, so that no more of oats or drege shall be given than the usual allowance for either horses or cattle. We have often, when the straw crop was not very heavy and containing young clover, harvested the crop entirely for the purpose of using as chaff, and found it save a considerable amount of labour. The ricks of corn will now, in many situations, be infested with rats. These may be disturbed by ferrets and shot on making their appearance. There are men, however, who undertake to clear the ricks of rats, and by smearing the ferrets with some kind of scented oils round the head and neck, which leaves so strong an odour in the rat runs that those which are not killed at the time of ferretting are sure to forsake the rick, and never return

again. We have never been able to obtain the secret of mixing of these oils; the men keep it to themselves, and turn it to their account by charging for clearing the ricks from these vermin. All the young cattle will now be required to feed in the sheds and yards at night time, going out at day time into dry pastures only with a small bait of cut roots and sweet straw for the heifers, but steers should have according to age from 2 to 3 lbs. of decorticated cotton cake per day mixed with 20 lbs. of cut Swedes each in addition to good straw as fodder. The Dorset down sheep will begin lambing before the month is out. They may have a few cabbages out on the pastures, but no hay until after lambing; if any dry fodder is required it should be sweet straw cut into chaff, with cake meal and water to damp the straw and make it palatable. The horned Dorset and Somerset ewes have now quite finished lambing; some of the earliest lambs will be sold at Christmas, but the trade for them is seldom open in the Metropolitan Market until the first week in February.

THE BIRMINGHAM POULTRY SHOW.

(Continued from page 439.)

Game.—Before beginning our remarks about the Game we must enter a loud protest against the position of the Black and Brown Red hens and pullets. There are no breeds in which colour tells more than in these—no breeds whose colours can so little help any deficiencies of light. If the Committee are bound to have pens in this unfortunate situation, birds whose plumage will best reflect the light should be chosen for it. For ourselves we are bound to say, that while we think Birmingham is second to no show in the way in which all its business is managed, it fails to rise to a due sense of its position as “the Derby” of the poultry year. All other shows must more or less tout for popularity. Birmingham has only not to invent means of throwing it away. Every class at Birmingham ought to partake more or less of a champion character. At such a show Selling classes should have no place. What we look for at Birmingham are the picked birds of the year. We have heard of people coming to Birmingham from the north of Scotland to see what a show ought to be. They are not likely to see this at Birmingham till weeding rather than increasing entries is the order of the day. Birmingham is the only Show at which we welcome rather than regret any increase in the price of entries. With this protest we pass to the Game. Nineteen Black Red cocks put in an appearance. First and cup went to Mr. Lyon's £100 bird. He is not quite up yet, but seems likely to fulfil the predictions of those who thought he might get full in hackle this year; but he is a fine bird, and should be able to recoup his owner in the breeding yard. Second was won by Mr. Dutton's cock bird, commended at the Palace. Mr. Tom Mason took third with a very smart bird, which, if he had been rather more willow in the leg and sounder in tail, might have been higher. Fourth went to Mr. Matthew for a fine bird, but rather red in the fluff and broad in tail. 1502 (Walters), highly commended, was a good bird and cheap. 1509 (Maynard), highly commended, was also good.

Black Red cockerels showed a great falling-off in style. Whether Hull has had anything to do with it we do not know, but there was no really first-rate bird here. Mr. Lyon's fifth-prize cockerel was about the best, and had he been in sounder condition could hardly have helped being first; as it was, Mr. Halsall took that honour with a bird of very pretty carriage, but not quite light enough in colour, and with an indifferent head, made worse by bad dubbing. Mr. Garne, a rising exhibitor, took second, but his bird wanted bloom. Mr. Matthew was third with a bird fine in head but too long in the tail, and not bright enough in the eye. 1527 probably did not look so well when the Judge went round as later in the day, or he might have been placed. 1531 (Walters) was cheap at the catalogue price.

In hens first was taken by Mr. Dutton's hen, which took the cup here as pullet last year. Second (Harley) a good hen, but with a poor eye. Mr. Pope was third with the hen second at the Palace. We very much liked 1568 (Goodwin), very highly commended, and should have been inclined to have put her second. Dark eyes seem on the increase. All the highly commended hens well deserved the notice, but the only ones with a really good eye were 1558 (Stagg) and 1565 (Maynard).

Pullets made up in quality for the deficiencies of the cockerels, and the Judge would have had no easy task had the birds been in the best light the Show could have afforded; as it was the task could only have been exceeded in difficulty by Mr. Lane's amongst the Brown Red pullets. The cup went to a beautiful pullet of Mr. Garne's, sister, we believe, to his bird that was so much admired at Oxford, and which we think we recognised here and preferred in his very highly commended pen, 1602. Second was taken by Mr. Halsall, as well as fifth, with two birds that looked much like those at the Palace. If these are the birds that were at Oxford they have greatly improved since then. We dislike the bluish tinge in their legs, but except that they leave little to be desired. The third-prize bird (Lyon) had a sprung comb and a red wing, but showed great quality, like the same owner's other birds—1599 (highly commended) and 1608 (very highly com-

mended). The fourth-prize bird (Pope) was first at the Palace. Amongst the noticed birds which we have not yet mentioned 1581 (Pope) was a fine reachy pullet, a little weak perhaps in the head, and not as brilliant in the eye as might be. 1583 (highly commended) a daughter of the first-prize hen, and with much of her mother's looks, but has not inherited her mother's good eye. 1591 (Frith), commended, was very lengthy, but not too good in head. 1593, highly commended (Phillips), had a very odd tail. 1597, highly commended (Maynard) and 1606, commended, which was one of the best-coloured pullets in the Show. 1600, highly commended (Pope), very much like the same owner's other birds, and full of quality. 1605, highly commended (Van Wart), very cheap at catalogue price. In Brown Red cocks Mr. Matthew took first with a cock that should have had the cup for the best cock in the Show. His legs were perhaps a trifle too willow, but with that exception he was perfect. Second, 1620 (Brierley), was rather red in face. We liked the third-prize bird, 1626 (Watson), better, but he had one of his claws broken. Fourth (Morgan) a very indifferent bird. 1618 (Martin) and 1628, commended (Tom Mason), were either of them better. In cockerels champion cup and second went to Mr. Brierley for two beautiful cockerels of Mr. Garnett's strain. The first is the better bird now, but the future belongs to the second. Third (Wolff) we could never get to hold himself together, either on Saturday or Monday. Fourth (Martin) wanted brightness, and was not up to Mr. Martin's usual form. 1651 (Fenwick) fifth, was the best-coloured bird in the class. His hackles were too full, but we should have placed him third. 1642, highly commended (Matthew), was rather high in tail. 1645 (Adams), commended, was good in colour but rather full.

Brown Red hens and pullets we cannot criticise. We cannot see in the dark. Mr. Matthew won the cup with the bird that was first at the Palace we believe, and which we thought should have had the cup there. Second (Fenwick) was a bird which must have made the Judge wish for two first prizes. Third (Brierley) was hardly brassy enough in the hackles to please us. 1657 (Tom Mason) was a good bird. 1663 (Watson), highly commended, had rather a brown wing we fancy. 1665 (Martin), highly commended, might have had a darker face. 1666, highly commended (Brierley), was too long for her pen. Brown Red Game hens want pens very little smaller than the cocks'. 1671 (Parker) we preferred to 1670 (Morgan), highly commended. In pullets Mr. Fenwick was first, Mr. Martin second, Mr. Brierley third, and Mr. Meredith fourth. Of these we may say that the first excelled in colour and the second in style, while the third had better colour than the second and more style than the first. Fourth was a good pullet with a nice swinging hackle. The following remarks concerning the noticed birds must be taken for what they are worth:—We thought 1672, highly commended (Voisin), was the unnoticed bird we admired at the Palace; 1673, highly commended (Ward), was bright but short, and had too much hackle; 1674 (Brierley), highly commended, had a good breast for cock breeding, but wanted a longer head; 1679, highly commended (Matthew), was very pretty; 1680 (Tom Mason), highly commended, might have been brassier; and we thought 1693 (Frith) should have had a card.

Duckwing cocks, and we are in the light again! Mr. Martin takes the cup with a bird much like his third Palace cock. We liked the first cockerel (Matthew) better, but Mr. Martin's is a very good bird. Second (Matthew) many preferred to the first. Third (Watson) was a fair colour, but a bad tail. 1709 (Oakeley) and 1712 (Staveley), both highly commended, were fair birds. If Mr. Matthew's cockerel was the same that was at the Palace he has recovered from the injury he there did his face by fighting. He is an excellent Duckwing. Second (Harley) and third (Lyon) were both fair birds. As to the noticed birds, we can only say that Mr. Lane takes a more charitable view of what a Duckwing ought to be than we do. In hens Mr. Matthew was first with an excellent hen; Messrs. Staveley second and third. Mr. Lyon and Mr. Goodwin both showed good birds, the latter with a very good eye. In pullets the cup went to Messrs. Staveley for the pullet which was second at the Palace, while the bird there first is here third. As our remarks concerning her were then misprinted we take this opportunity of saying that though the third (Harley) is very good in shape the first beats her in colour and eye. Second (Lyon) has a dark eye too. Good eyes are becoming almost extinct. 1750 (Lyon), highly commended, might have been “Black-eyed Susan” herself.

In Pile cocks there was a mistake about Mr. Halsall's bird (1754). He was the best bird in the class, but Mr. Lane, misled by his short spurs, thought a chicken had been sent by mistake. What was decided as to a prize for him we do not know. As it was the Duke of Sutherland took first, and the Palace first cock was second. 1755, highly commended, had a light eye. In cockerels Mr. Halsall took cup with a bird good but for his tail. Second (Mrs. Bell) was light in eye, but otherwise good. Highly commended, 1766 (Crowther), pretty, but thickish head. 1759 (Otter), commended, pretty; and 1763 (Pratt), a white-legged bird of very good style. Hens.—First (Adams) the Palace bird apparently. Second (Halsall) was high in tail. We preferred 1770 (Walker), highly commended. 1774 (Brierley), highly com-

mended, was also very good. In pullets Mr. Brierley took first. Second went to Messrs. W. & R. Smith for a pretty pullet. 1776 (Halsall), 1781 (Mrs. Bell), and 1786 (Brierley) were all highly commended. 1783 (Clare), commended, we liked quite as well if not better than the second. Cocks, any other variety, contained a motley collection of Blacks, Brassy-winged, Silver Duckwing, White, and Indians. Dr. Etheridge's Silver Duckwing was a bird of very good carriage, though he ought not to have won in this class, and for a Silver Duckwing his hackles should have been clearer, and his saddle was too yellow; but we are grateful to Dr. Etheridge for having the courage to show a Silver. We may say for the encouragement of Silver Duckwing breeders that we know Mr. Smith is quite prepared to award them prizes in the Duckwing class, provided they are as good as Silvers as the Yellow Duckwings are as Yellows. If all judges would do the same we believe Duckwings would vastly increase in numbers and style. We doubt if the King of Oudh would acknowledge Mr. Swift's Ghaguz as having come from his yards. The hens had as great a variety as the cocks. Mr. Montresor was first with a Black pullet of fair style, but too dark in the eye for a Black Game. Mr. Brierley was second, and Mr. Meredith third.

Hamburgs.—Blacks, which were provided with twice as many classes as their Spangled and Pencilled relatives, came first in these beautiful fowls. In Black cocks first was a fine bird in good condition, good white ears, rather broad in comb. Second a fine handsome glossy bird, good in ears and comb. All the noticed birds were good. In cockerels, first, which won the cup for the best Black Hamburg, was a very handsome bird, with capital comb and ears and fine gloss. Second a very good bird with fine head. Third another good glossy bird. This was a splendid class, all the mentioned birds were really good. In hens first was a very green lustrous hen, splendid in colour though not quite perfect in head points. Second was also a very good hen. The other honoured birds were all birds of merit. In pullets first was a pullet of good head points and first-class lustre; she was a beauty, and very much like the Palace winner, if not the same bird. Second was a very similar style of pullet, good all round. Third very lustrous and good in other points. The commended birds were again all meritorious, and we did not see a failure amongst them. In the remaining Hamburg classes all ages competed together. In Gold-pencilled cocks first, an adult entered at ten guineas and labelled sold, was a very handsome bird, good in comb and ears, rich in colour and beautifully laced tail. Second was a pretty cockerel, good in colour, but rather inclined to white in the face. Third a rich-coloured cockerel very good in ears. 1248 (Beldon), 1249 (Pickles), and 1251 (Long) very good indeed. In pullets first was a pretty pullet, very clearly pencilled and good in ground colour. Second a very handsome pullet, good in pencilling and beautiful ground colour. Third a bird in fine condition, very glossy, but not so fine in pencilling as the preceding. 1268 (Smith) the Palace winner, very correct in pencilling, but a little pale in ground colour; 1263 (Harding) good. In Silver-pencilled cocks first-and-cup for this variety was one of the Norwich disqualified birds, a very handsome bird with grand tail. Second a very good one with finely laced tail. Third a fair bird, and the commended birds also good. In hens first was very sharp in pencilling and good in comb and ears, also clear in hackle. Second very well pencilled and in nice trim. Third a well-pencilled pullet. 1277 (the Duke) a good bird. In Silver-spangled cocks first-and-cup a very handsome bird in fine condition, well-marked breast, wing, and tail, and good head. Second a well-marked bird, good in comb and ears. Third good head and well marked. 1285 (Campbell), good. In hens first was beautifully spangled throughout, and with good comb and earlobes. Second was splendidly marked and good in ear, but rather loose in comb. Third a good and well-marked hen though rather dark. The honourably mentioned birds were all good handsome birds. In Golden-spangled cocks first-and-cup rich ground colour, well barred wing, and good breast. Second a good rich-coloured bird, well marked, good ears, though scarcely perfect in comb. Third a showy bird, good in comb and ears. 1800 (Hyde), very good in head; 1301 (Jackson), very rich in colour and good in ears. All the other mentioned birds were good. In hens first rich in ground colour, a well-marked bird, fine comb and earlobes. Second a handsome hen, rich in ground colour, good in head, very correct in marking. Third well marked and good in head. 1318 (Jackson) a good rich-coloured hen.

PIGEONS.

Carriers.—Black cocks.—First had wonderful head and beak properties and was well shown. Second a very fine bird with fine eye and beak/wattle. Hens.—First very fine, good eye wattle. Second also a first-class bird, very fine in beak. **Dun cocks.**—Cup a splendid bird, very good in head properties. Second a very good bird and well shown. Hens.—First was grand in wattle. Second a very good hen, fine in eye. In Carriers of any other colour both the winners were good Blues. 2189 (Cant), a good one. In young Blacks the winners were both very good and promising birds. This was a good class. In young birds of any other colour the winners were good Duns, first winning the cup for young Carriers. In Pouter cocks (Red or Yellow), first a very good Red with fine crop. Se-

cond a good stylish Yellow. In hens both the winners were good Reds. In Blue cocks first a fine-limbed bird, very good. Second a good bird. Hens.—First a fine slim bird. Second good. White Pouter cocks numbered six and hens seven; the winners in both classes very good. In Pouters of any other colour each class contained six entries; all the winners Blacks of fine quality. **Almonds.**—First-and-cup good in head and well broken in colour, a very good bird. Second a very good-headed hen. In any other colour Short-faced Tumbler, first a very good whole-coloured Red. Second a good Black Mottle. In Balds and Beards, first a fine Blue Beard. Second a very good Silver Baldhead. **Barbs.**—Seven old birds were shown. First a beautiful Black; second a Red. They were both in capital condition, as well as being very perfect in head. Mr. Fulton's celebrated Red was not noticed, owing probably to want of condition. Six young birds appeared; the prizes went to two pretty Blacks, not so fully developed in wattle as others in the class, but we suspect the Judge had doubts about the ages of some of those which looked the best. **Trumpeters.**—In Mottles a very dark bird first, a light second. In the Any other colour class a really good White was first, now a *rara avis*; it is only at Birmingham that we ever have the pleasure of seeing representatives from Mr. Shaw's yards and aviaries, which must be most interesting. **Runts.**—The wonderful Parisian Silvers won again. Archangels were poor for Birmingham. First a good purplish bird, and second a good bronzy bird, the rest not very good. **Fantails.**—The cup went to a pretty little White with rather irregular tail. Second we thought the best in the class, small, with beautifully flat tail. Third a coarse bird but with some motion, and very long and broad tail feathers. In Any other colour, Blues won; the first fairly flat in tail. **Nuns.**—All the winners Black. **Swallows.**—A very pretty class. The sectional cup went to Mr. Bulley's lovely Black. Second a good Yellow; third a Red. **Maggies** a very large class. First a Yellow; second a very rich Red; third a Black. **Jacobins.**—Twenty-three Reds and Yellows. The cup went to a lovely little Red; second a Red rich in colour and close in hood, but coarser than the first. Third a Yellow, generally good, but not quite round enough in hood. Any other colour.—First a capital Black with head completely buried in its hood; second a Black, good in hood, rather long in beak; third a White. **Turbits.**—In the Red or Yellow class both prizes went to Yellows. First small and good in colour; second superior in head but less rich in colour. In the Any other colour class a Blue was first, good in head and fair in colour, with rather broad bars; second a small Silver. **Owls.**—In the Foreign class the winners all Whites. In the English class the cup went to a grand Silver, splendid in beak and gullet. Second a slightly powdered Silver with full frill and good face. Mr. Woods' highly commended Blue a good bird. **Dragons** were few—only forty-eight entries for nine classes. We do not believe that the popularity of this breed is at all waning, but that fanciers will not send their birds to be knocked up in the Birmingham atmosphere. The three cups were all taken by Mr. Woods; his winning Blue and Silver cocks were remarkable. We also liked the second Grizzle cock, though he is perhaps too Carrier-like in beak. Mr. Woods' cup Yellow hen was particularly rich in colour. Antwerps were well represented; there is always much sameness in these classes. Mr. Eckroyd's cup Silver Dun cock was about the finest specimen of the variety we have ever seen, and the same gentleman's cup Red Chequer extremely good. Short-billed Frilled varieties made a large class, though many of them were in poor condition. First was a Satinette, and second a Blondinette. Any other variety.—Mr. Bulley's Blue Priest first, second a Spangled Ice Pigeon, and third a Black Fairy Swallow.

MID-SURREY POULTRY SHOW.

THE third annual Exhibition was held at Kingston on Thursday last and following days. The classification this year was judiciously curtailed, and the value of the prizes improved by the money so saved. The result was that many of the most noted exhibitors supported the Show, and hence a visible improvement in the quality.

Dorkings.—In Coloured Mr. Brown won with a capital pen which we do not remember to have seen before, defeating two or three of the cracks. Any other colour poor; first prize withheld. **Cochins.**—Partridge and Buff thirteen entries, Buffs first. Any other variety, first a beautiful pen of Whites well known. **Brahmas.**—Darks and Lights good, Mr. Lingwood winning in both classes. **Minorcas** and **Leghorns** shown together made the largest of the poultry classes, and will, we presume, offer a sufficient encouragement to the Committee to divide them in future. **Polands.**—First a pair of nicely crested birds. **Andalusians.**—Mr. Boissier's pen that we think obtained the third prize at Bexley was here promoted to the first position, and the pen of Mr. Wiggins that was first at Bexley only obtained a highly commended card. **French.**—Hondans eleven entries with some good names in the catalogue, but we could not find a good pen of birds. Pen 202 unnoticed (Vallance) appeared the best, but we were informed the cock was not quite straight in the tail. The winning cock was a moderate bird; the hen was large but gouty on one foot

and carried her crest on one side. Any other variety only five entries, no novelties; second and third prizes withheld. *Bantams*.—Moderate classes. *Ducks*.—Good in quality but few in number.

Pigeons.—Pouters a poor class of four entries, first prize withheld. Carriers, the classes were not so well filled as we expected, but a few high-class birds were to be seen, Mr. Hammock being first in the Any other variety with his Crystal Palace winner. Dragons five classes: we thought them the best in the Show, and with the exception of the Antwerps these were the largest in numbers. Blue and Silver cocks, Mr. Lush was the winner with a nicely coloured Blue; second and third Burnell. Blue and Silver hens, first a magnificent dark hard-eyed bird, very sound in colour with splendid bars, the best we remember to have seen for a considerable period. Any other colour cock, first a Yellow, very even in colour but poor in head; second a Chequer, the Palace winner. Hens, first a Yellow, very rich in colour, but so wild she must have given the Judge some trouble. Young birds, Any other variety, first a beautiful Blue, the Palace winner. In Tumblers, Jacobins, and Turbits Mr. Boxall, a local supporter, to the astonishment of many exhibitors succeeded in winning all the first prizes. Mr. Boxall we see also won prizes in Pouters, Carriers, and Dragon classes. Such a success is almost unprecedented. Mr. Boxall's large entries helped to compensate the Committee for the loss of Mr. Baker's patronage, who was the largest exhibitor on the last occasion, but this year did not show. Antwerps were large classes. An improvement in the arrangements was made by placing the small birds on the stage, and we would suggest on a future occasion double rows of staging in lieu of single, as the birds generally turn their faces in opposition and inspection becomes very difficult.

Mr. Nichols judged the poultry, and Mr. Jones the Pigeons.

CONTAGIOUS DISEASES IN RABBITS.

SOME of these diseases are hereditary, and nothing can eradicate them except death. There are other diseases which are perhaps more frequent that are caused by neglect, and are easily prevented by proper precautions.

There are many diseases caused by a want of care in the provision of moist food. When this is given too freely looseness is the result. If left it soon becomes very weakening, and will cause death, especially when the patient is young. The remedy is to vary the diet. Plenty of dry corn and bran are the best; at the same time green food should not be entirely neglected, as constipation is not at all unlikely to follow. If this is discovered at once, a little extra green food or a handful or two of tea leaves will remove the disease; but if it continues very long, more effective remedies will have to be tried. It may be necessary to entirely stop the supply of corn and substitute roots and greens. In this case the Rabbit should be carefully watched, and directly the desired effect has been attained the old diet should be resumed, but a little more green stuff introduced as a preventive. If this complaint is neglected death is sure to follow, and pretty rapidly. Frequent attacks of constipation and a continual diminution of the supply of green food produce diseases which are increased by dirty or dark hutches, dampness being peculiarly objectionable.

The most common disease is a form of scurvy very disgusting and very contagious. It makes itself known by scales which come on the head and neck, and sometimes on the back. As it is very catching, any Rabbit afflicted with it should be immediately killed unless it is particularly valuable.

Another disease very similar to that one is the mange. The hair on the nose and at the root of the ears comes off, and the flesh is covered with a horny scale even more disgusting than scurf. This complaint is also catching, and should only be dealt with when the Rabbit is of a good strain. The best remedy for these complaints is brimstone. This may be mixed with something greasy and rubbed on the parts affected as a salve, or it may be given internally by mixing a little of the powder among the dry food. Of course any animal affected must be removed from healthy Rabbits. Great care should be exercised in purchasing from strangers, as a mangy Rabbit will affect a whole rabbitry in a few days.

Red-Pot-belly is the name given to a disease caused chiefly in young Rabbits by a constant wet diet. Too much green stuff, especially if wet, will cause this complaint to come very rapidly indeed, and its result is much more serious than is expected. The belly swells to a great size, often making the skin tight. Very often an internal stoppage is the immediate cause of death. On dissection it seems that the whole intestines are affected. The remedy is to make the Rabbit have plenty of exercise, and to drive it about a little. At the same time all green food given should be carefully dried, and the amount should be limited. The dry food must not be neglected, and the Rabbit should be tempted to eat. Many young ones die of this complaint. Judicious feeding and plenty of daily exercise are sure preventives. Old Rabbits are very seldom troubled with this disastrous complaint.

Another effect of injudicious feeding is indigestion, which if not checked in time will end in fits and giddiness. The signs of

the disease are the Rabbit retires to a corner and bends its head repeatedly on one side, looking languid and sad, and not noticing anything. It still continues to eat with vigour, and very often is troubled with costiveness. A good supply of green food with plenty of fresh air is the best remedy. If young they frequently die from the complaint. When badly affected they lie on their sides and backs and kick violently, the fits being of frequent occurrence. At other times they run round and round.

Among the other complaints that are preventable may be mentioned coughs and cold, generally called snuffles. These are indicated by sneezing and running at the nose. The best cure is to keep the Rabbit in a warm hutch, and supply it with warm mash, the best being barleymeal.

Dirty hutches cause many more complaints, especially when accompanied with much warmth. These will be treated of later on, as will also the chronic and hereditary complaints.

Rabbits are liable to have disagreeable discharges from the ears, which often coagulate and assume a waxy appearance. The best treatment is, directly any of it makes its appearance, to pick it out gently, and apply a little sweet oil. This should be repeated daily till the cure is effected.—GERA.

VARIETIES.

At the Smithfield Club Cattle Show held in the Agricultural Hall Islington, this week, Mr. Stratton was awarded the £100 prize for the best beast in the Show with his beautiful Short-horned heifer which won the same prize last year, and also the first prize on both occasions in the Short-horned heifer class. H.R.H. the Prince of Wales, who visited the Show on Monday, warmly congratulated Mr. Stratton on his remarkable achievements. The number of entries in the Show is 401—namely, 182 in the cattle classes, 156 in the sheep classes, and 63 in the pig classes. The Exhibition throughout is one of great excellence, all the animals appearing in capital health. As an instance of the remarkable manner in which the Show has increased, it has only to be noted that in 1800 the number of classes was six, and the amount of prizes £126; this year there were seventy-six classes, and £3000 offered in prizes.

At the Birmingham Cattle Show the collections of roots exhibited by such firms as those of Messrs. Sutton & Sons, James Carter & Co., and E. Webb & Sons, attracted much notice by their magnitude and excellence. We recently noticed the fine exhibitions provided by the above firms, and it is only necessary to say now that the roots at Birmingham were selected as the best from the previous displays, and the remarkable character of the produce will be admitted. The firms also exhibit similarly splendid produce at the Agricultural Hall, Islington, this week.

In Europe, and Austria especially, cows are said to be fed on the leaves of celery cut and mixed in their feed. It is said to give the butter an excellent flavour. The Dutch, or turnip-rooted celery, is easily raised, and both tops and roots may be fed. The experiment may be worthy of trial.

At the Dorset County Poultry, &c., Show to be held at Dorchester on January 15th and 16th, 1879, we observe that prizes amounting to £250 will be awarded, including three silver cups given by W. E. Brymer, Esq., M.P., for Dorkings, Brahmas, and Cochins; also a silver cup, value five guineas, presented by Lord Alington, President of the Society, for the best pen of fowls in the Show, being the property of and exhibited by a resident in the county of Dorset.

The annual sale of poultry from Lady Gwydyr's yards is advertised to take place at Stoke Park on Tuesday, 17th inst. These celebrated strains have so long been carefully bred that fanciers who wish to improve their stock of Cochins or Brahmas should not lose the opportunity of attending this sale, which it is well known is always a *bona fide* one.

The number of visitors to the Birmingham Show was this year much larger than last year. Possibly this may be owing to the attraction of the electric light. The aggregate sales of poultry varied little from last year. Among them we observed that Mr. Mitchell's cup Light Brahma cock was sold for £20; Mr. Rutledge's first-prize Dark Dorking cock for eight guineas and a half; Mr. Lee's first-prize Houdan cockerel fetched £15 at the auction, and Mr. Serjeantson's cup Silver-laced Bantams were claimed for £20. We heard also that £25 was offered during the Show for Lady Dartmouth's Silver Polish hen, but refused.

The electric light in Bingley Hall cannot be pronounced a success. It had frequently to be supplemented by gas, and the atmosphere of the Pigeon gallery was only a few degrees less heated and fetid.

Writing on the health and disease of fowls an American poultry journal observes—"The comb of each fowl is a true index to their condition. If they be in ill health the comb will lose colour and will become far less firm in texture; as the malady increases the colour decreases, till a very sick bird will show a comb almost devoid of scarlet colour, being of a livid dull crimson or else pale or ashy in appearance. If any disease should come

into the flock carefully examine the combs of each bird morning and night, and all those which are wanting in that bright rich colour which denotes perfect health remove at once from the flock to a place remote, where they should be at once put under medical treatment. The comb of the fowl should daily be consulted by the fancier who values the health and well-being of his flock. Look at the comb of a laying hen or pullet! She is in the height of health and strength and carries her unflinching sign of healthfulness on her head, in the shape of a blood-red bright and full comb. A vigorous cock or cockerel will carry the same sign, though not perhaps, in so eminent a degree."

At a meeting of the Superior Commission on the Phylloxera in France, M. Teisserenc du Bort reviewed the present state of the question. The number of infected departments has increased from 28 in January, 1877, to 39 at this date. Out of 6,380,000 acres one-fifth is entirely ruined, while a second fifth threatens to follow suit unless efficacious remedies be adopted. On the proposition of the Minister two vice-presidents were elected. Three sub-commissions were also appointed; one for the examination of proposed remedies, the second for the demarcation of the infested zones and the preparation of circulars and decrees, the third for the recommendation of curative measures.

The French Chamber of Deputies have voted the Budget of the Minister of Agriculture and Commerce, comprising a sum of £504,000. Of this £308,630 are devoted to the improvement generally of the breed of horses. The residue is allotted thus:—Improvement of the breed of cattle, £11,600; veterinary teaching, £37,900; agricultural tuition, £69,200; drainage, £1340; agricultural societies, £20,000; shows, £40,150; inspection of agriculture, £5900; studies on the diseases of the vine, £9280.

TAKING HONEY.

MAY I suggest what I think an improvement on the process given at page 381 for the extraction of honey from the comb, as I manage it myself? I used to squeeze it out in the way described, but disliking it extremely, partly owing to what some may consider over-fastidiousness, not liking so much handling of the honey, and partly from the disagreeableness of the operation itself, I have for many years preferred to drain the honey out of the honeycomb by cutting up the latter in a colander, the said colander being arranged over a large earthenware pan. No doubt the process is somewhat longer in operation, but in cleanliness and niceness (if I may use the term), it is to my mind a far preferable mode of extracting the honey, as avoiding so much manipulation. The combs are carefully separated from one another as described by your correspondent (and the sooner the better after the removal of the bees), then beginning with the finest and purest honeycomb, it is all cut up like mince into the colander. The honey passes off very rapidly, and the purer the comb the firmer is the residuum of wax, which indeed requires but little time or labour to reduce it to a state fit for use. It must be said, however, that most of this sort of honeycomb is retained whole, and kept for home use or sale as such. The second best honeycomb requires more care, but it is treated exactly in the same way, only more time is given to the cutting away of every possible particle of pollen. Treated thus the extracted honey is little if at all inferior to that which I have described above. All the other combs are then finally separated. Some go into a basket or large box, and are spread out for a feast, open to all bee-keepers; the remainder is treated as before, but without the same minutely scrupulous care as to bee bread. It is, of course, inferior honey but good for many purposes. I give these combs away to some poor neighbour who does not mind the trouble of extraction.—B. & W.

SWARMING AND NON-SWARMING.

RESULTS COMPARED.

MR. B.—I trust, Mr. P., you will excuse my coming to see you once more, when you know that I am concerned to learn whether the swarming or non-swarming system of managing bees should be adopted and followed. I want to know which is best and most profitable, and therefore have come to ask advice.

MR. P.—I am glad you have come, if only to learn that hundreds of earnest practical bee-keepers are in the same perplexity, and are as anxious as you are for light on the subject. The question you have come to ask is one of great interest and importance to all earnest and intelligent apianians. For many long years I have been examining this question from every possible standpoint, and if I can help you at all I shall be glad. What is your greatest difficulty in considering the subject?

MR. B.—Well, sir, I watch all that is said in the journals about it, and find that some honest practical men are biased in favour of the swarming system, and others equally honest and intelligent are biased in favour of the non-swarming principle. I want to know which is right.

MR. P.—Probably both sides are right, for no system concentrates within itself all advantages. The fact that men equally honest and intelligent are biased in opposite directions admits of

an explanation. Some seasons are favourable to the swarming system, and some to the non-swarming one. In some districts it is advantageous to promote swarming, in others to prevent swarming. Again, run honey is readily sold in one locality and honeycomb in another. While many amateurs object to the multiplication of hives, many practical bee-keepers amongst the working classes believe there is less risk and more profit in the swarming system than in the other.

MR. B.—Will you explain how it is that one season is favourable to one system and not to the other, and *vice versa*?

MR. P.—The non-swarming system of management has comparatively great advantages in bad seasons, in late or short seasons, and in some seasons not very favourable for honey-gathering. In bad seasons all hives have to be fed, and the expense is so great that we all wish then we had fewer hives. In unfavourable seasons it is bad policy and practice to remove a queen from a hive in which breeding is going on rapidly, and put her with a swarm into an empty hive wherein her eggs cannot be used. Swarming or separation in such seasons is hurtful to both. The parent hive is crippled and greatly disabled for work, and the swarm being without capital gets into difficulties at first which without artificial aid it cannot surmount. In poor short seasons there is little time to spare for comb-building or for filling empty hives. Concentration of the effective forces of the whole army is necessary in the hour of battle.

MR. B.—What other advantages does the non-swarming system possess?

MR. P.—It keeps the apiary in a compact form—every year the number of hives is round and equal. Supering being the aim of the non-swarming apianians, they obtain great harvests of honeycomb in fine seasons if their hives and supers are large. For great results ample room for breeding and storifying is necessary.

MR. B.—Has this system any or many disadvantages?

MR. P.—Yes, many. It is opposed to the natural laws of bee life and development. It is as natural for bees to swarm in ordinary and fine seasons as it is for water to mix with water, and efforts made to prevent swarming are often unavailing. Bees will multiply and go off in spite of all that can be done to prevent them. The risk of losing swarms on the non-swarming system is great, and should never be forgotten. On this system, too, queens become old and die; combs become black, old, and pollen-bound.

MR. B.—Will you name the advantages of the swarming system?

MR. P.—It has already been said that swarming is in the line of nature, and accords with the instincts of bees. Nature is very wise—giving saltiness to the sea to preserve its sweetness, and swarming instincts to bees that their existence may be preserved and their decay prevented. By this system old generations give place to new ones; old combs and old queens can be advantageously removed and put aside; indeed, all old things pass away and all things become new, for in swarming hives we have new interests, new combs, and new life. "Multiplication" leads on to "the rule of three," and three hives from one in early good seasons do far more work and breed more bees than a single non-swarming hive. On the swarming system the practical apianian has lots of bees—nays, swarms of bees from honey hives to dispose of in autumn. He can use them with very great advantage in making his stock hives doubly strong in bees, and by feeding his super-numerary swarms in empty hives he can increase the number of his stocks.

The disadvantages of the swarming system have already been mentioned, which you will remember—viz., the weakening of stock hives in the time of honey-gathering, the consumption of honey in filling swarm hives with combs, the feeding of swarms in bad seasons, &c.

MR. B.—Which system do you practise?

MR. P.—I practise and recommend both systems, for I believe that both should be adopted and followed in all apiaries of four or six hives if profit be the aim of the bee-master. You want profits from your bees every year; muffins—real muffins—not the mere promise of muffins, and therefore I advise you to follow the swarming system with one half of your stock and the non-swarming system with the other half. Both systems go well together. By the swarming system you will have a choice of hives with fresh combs and young queens in them, and plenty of bees from honey hives to make them strong in autumn; and please to bear constantly in mind that great success next season depends greatly on the autumn treatment of bees this year—that is, to say, the striking results of success—the well-buttered muffins—come from strong hives.

I should be glad if I could help you by referring to my own practice, but this would not help you. The multiplying system suits me best just now, for I can sell all the good hives in my garden at good prices; in fact, during the last three or four years it has been difficult to retain strong hives in my apiary. Ladies and gentlemen, and working men too, will have them, and under their importunities I let them go. This year I have stronger hives than I have had for five years. Two-thirds of them will be managed next year on the swarming principle, and the other third on the non-swarming system. Run honey here sells as readily as honeycomb at 1s. 3d. and 1s. 4d. per lb.

Mr. B.—Have you any records of results this year which we could compare and analyse?

Mr. P.—I know of two reports only of bee-keeping this year that can be compared, and neither of them is full or complete. The first is that of a Scotch clergyman who had a good harvest of super honey from eight Stewarton hives—viz., 445 lbs., as reported in the *Journal of Horticulture*. One of these hives yielded 92½ lbs. of this sum total. The other report comes from James Somerville, a working man at Carlisle, Lanarkshire. His hives are made of straw and managed on the swarming principle. The gross weight of one of his stock hives and its swarms was 352 lbs. From his five hives Somerville had 350 lbs. of run honey and 64 lbs. of honey-comb in supers. He sold his run honey at 1s. per lb. I do not know what he got for his honeycomb, but comb is generally sold in Glasgow at 1s. 3d. per lb.—i.e., 3d. higher per pound than run honey. Neither do I know whether the clergyman sold his or not; but by taking the usual price in Glasgow of comb in good seasons we shall not go far wrong in our calculations of the money value of the results. At the prices indicated you will see, Mr. B., that the profits of the eight Stewarton hives this year have been £27 16s. 3d., averaging £3 10s. per hive, and that the profits of the five straw hives managed on the swarming principle have been £21 10s., averaging £4 6s. per hive. If the wax of the straw hives be taken into account the profits would be quite £4 10s. per hive, leaving the Stewarton or non-swarming system 20s. per hive behind. But remember that the clergyman spoke of getting a harvest of run honey from his breeding boxes in addition to his super honey. If he has taken 20 lbs. averagely from each hive, or 240 lbs. altogether, his results will be equal in money value to those of the straw hives. And I am sure that I would be gratified to learn that he has done all this. It would be a great happiness to me to tickle them "equal best." The results in both cases are satisfactory and encouraging. Both gentlemen are able apianians, and doubtless are living in pretty good localities for bees. For such results, probably the highest models of success in 1878, we are indebted to the clergyman of Renfrewshire and the poor thatcher of Carlisle, Lanarkshire.

Mr. B.—Have you forgotten that the clergyman's bees were first-cross Ligurians?

Mr. P.—No, but I attach no importance whatever to that fact. I have no bias in favour of common bees nor prejudice against Ligurians, but the superiority of the one over the other appears to me to be only visionary. During the last twenty years no satisfactory proof of any superiority has been produced. There are so many people anxious to hold up the Ligurian bees that if any evidence can be found of their superiority the country will soon hear of it. For the grand results we are now considering and comparing we are indebted more to the size of the hives than anything else. Hives of any kind, any materials, or construction, measuring 18 inches deep and 14 inches wide, or 18 inches wide and 14 inches deep, filled with either black or Ligurian bees, or cross-breeds, will gather a prodigious amount of honey.

Mr. B.—You seem to attach very little importance to the shape and construction of hives.

Mr. P.—Very little indeed. We cannot help bees, and we cannot make them more industrious than they are. Let yours have plenty of breeding and store room and your success will be greater than you imagine.—A. PETTIGREW.

SOME BEE EXPERIENCES OF 1878.

LAST season I used zinc adaptors with round perforations on two frame hives, and in one case I found the queen in the uppermost of the two supers which had been last put on. As she had only found room for a small amount of brood she had evidently only penetrated there late in the day. Both supers were quite full, and the lower quite free from brood. Her majesty was as slim as a princess, and consequently I am not surprised at her squeezing through the perforations. It was a stock which had not swarmed, but which I had strengthened by the addition of a small cast; possibly this was the queen of the cast. I am sorry I had not leisure to examine the stock to ascertain if there was another queen. It would be interesting to know the experience of others as regards zinc adaptors as to whether my experience is exceptional or not.

I also found an incomplete queen cell built on the wooden dummy occupying the place of the side of a Cheshire hive. I never before found a queen cell built on the side of either a straw or wooden hive. Is it exceptional?—O. B.

OUR LETTER BOX.

KEEP OF FOWLS (A Subscriber).—It is impossible to estimate the expense, so much depends upon the breed, season, locality, and object—whether for eggs, chickens, or exhibition.

HENS FOR LAYING (T. A.).—We advise you to keep Andalusians.

CANARY TREATMENT AND EXHIBITING (Voice).—Judging from what you state respecting the distressed condition of your Norwich cock bird, we have no doubt it is suffering from severe asthma, the result of cold and the

removing of the bird into a different atmosphere. The difficulty of breathing and the painful and unpleasant creaking noises the bird utters are sure signs that life will soon terminate. Cayenne pepper will not cure it of the complaint, especially considering the advanced state of illness. The periodical moulting has very much weakened the bird's system. Give the sufferer a few drops of cod-liver oil mixed with a small portion of soaked bread, in addition to an occasional bread-and-milk diet. You had better procure another cock bird of last season's breed, one not pepper-moulted. Three or four pairs of Norwich birds, clear or marked, according to fancy, will find you ample attention until you become better versed in the hobby of Canary keeping and breeding. Purchase a treatise upon Canaries. At present we should not advise you to pursue the cayenne-pepper system of moulting. It is not only expensive, but you must not expect to make headway in the fancy, especially in the way of successfully competing at bird shows in the peppered classes, with those who have become adepts in the art of moulting Canaries of very high colour. There are classes for non-peppered Canaries at the Crystal Palace, Norwich, and other well-known exhibitions, in which you would stand a better chance of getting a position if your birds be sent in a clean condition. Even before then you will have to learn how to wash a bird or get someone to manipulate for you.

GOLD FISH MANAGEMENT (F. W.).—Draw off the water almost entirely every day by means of a siphon. A piece of india-rubber tube makes the best of siphons for emptying a glass globe, it is so flexible and manageable. River water should be employed. Keep a few aquatic plants in your aquarium, and give the fish a very few small pieces of vermicelli daily. There should be some clean pebbles and sand at the bottom of the globe for the fish to scour against. We do not know the cause of their becoming partly black. Can any of our readers state the cause or remedy?

REMARKS.

- 4th.—Fine pleasant day, clear bright sky at sunset; moonlight evening.
5th.—Foggy morning, overcast but dry till 3.45 P.M.; rain until 7 P.M.; moonlight night.
6th.—Beautiful bright, clear, frosty morning, very fine day; snow commenced at 8.45 p.m.; cloudy night and snowing.
7th.—Raw damp morning, snow melting, dull and overcast all day; flakes of snow in the evening.
8th.—Fair and dry, bright sunshine at intervals during the morning; little thick in afternoon; night fine.
9th.—Cold, but very bright fine day throughout; moonlight evening.
10th.—Thick white frost in morning, very cold all day, no sunshine, overcast and rather thick.
Very cold, mean temperature nearly 8° below the average.—G. J. SYMONS.

COVENT GARDEN MARKET.—DECEMBER 11.

THE only improvement in our Market is amongst late-keeping Apples, such as Wellingtons, Blenheim's, and Nobs, all of which are in good demand at higher rates.

PREPARATIONS FOR CHRISTMAS.

GREATER unanimity is shown to welcome in old Christmas than at any other festival to which anything like national observance is accorded. Sad indeed must be the condition of an individual to whom its joy-bells bring no good tidings—no kindly emotions either in the guise of pleasant memories of the past or the warm grasp of friendship; the cheery salutations of "A Merry Christmas" from gathering friends and relatives, or even the more matter-of-fact delight of the humble tiller of the soil in his abundant Christmas supply of warmth and good cheer.

Christmas is coming, and special preparations must be made in the garden, the house, the church, the market. A busy time it is, therefore, especially for the gardener; for does not he wish to make the surroundings of the house as trim and ornamental as possible, so as to be in keeping with its interior decorations? To this end miniature shrubs, many of them gay with berries, are planted in the flower beds; shrubby borders are forked over, the shrubs pruned, and the prunings turned to account for church and household decoration. The latter is frequently an elaborate affair involving much time and painstaking, the greatest difficulty often being to hit upon some new design, something different to the efforts of former years. Good taste will, of course, lead to satisfactory results. Without it there should be no ambitious flights, no aiming at novel effect, but rather a quiet tone should prevail with plenty of warmth about it. Spiral wreaths to pillars, festoons along walls between pictures, Ivy along cornices and architraves, neat wreaths of Box, berried and variegated Holly, Laurustinus, and Cotoneaster around pictures, mirrors, and doorways.

For a Christmas tree there is nothing better than a Spruce Fir planted in a tub or barrel with the head knocked out and filled with moist sand. Let the tub be large, so as to avoid all risk of an upset; let the lower branches of the tree be well fastened to it with cords to keep all steady, and cover both tub and cords with green baize. If there is a large party, say about fifty children, and a lofty room can be had, the tree should be quite 15 feet high, to afford space on the branches for presents and the usual accompaniments of flags, Chinese lanterns, and other candle holders and ornaments. Have plenty of flags near the top of the tree and on the ends of the branches, and take care there is nothing inflammable immediately over the candles. Three or four tapers on long sticks will be wanted for lighting, and there should be a few pieces of damp sponge also on long sticks at hand for extinguishers in case of anything taking fire.

Dinner-table decoration at Christmas to be seasonable should consist of wreaths, or rather scrolls, of foliage springing from an encircling wreath around the centrepiece and winding lightly and gracefully upon the tablecloth among the dessert dishes along the sides of the table to the ends. It is not easy to convey a clear idea in writing as to the formation

of scrolls, the eye and hand of an artist being requisite to do them really well. They consist of long sprays of Lycopods, the blue-tinged *Lycopodium cæsum* being a special favourite; small fronds of Maidenhair Fern, and leaves of *Cissus discolor*, *Phyllanthus roseo-pictus*, pink-marked Crotons, Oak-leaved and tricolor Geraniums, sprays of *Panicum variegatum* and *Tradescantia zebrina*, with any other foliage of a light and ornamental character. A bowl of flowers may form the centrepiece, but tall stands are not much used now, strong objection being taken to obstructions and floral screens along the centre of the table. If there is a chandelier it may be turned to account for the suspension of small clear glass globes dressed with Lycopods and Ferns, with just one spray of bright toned flowers in each. Above these among the lamps there may be a wreath of *Arbutus* sprays bearing crimson berries and waxen blossom mingled together, or the entire centre of the chandelier may be filled with the dark green foliage of *Iris foetidissima* relieved by a few clusters of its gay scarlet berries overhanging a wreath of Mistletoe—not a heavy overpowering affair, but with the sprays clustering lightly together in just proportion to the size and form of the chandelier itself.

Of church decorations I am not disposed to enter particularly into any one method, for to take a narrow view of such a subject would be contrary to the genial fraternal spirit shown by both readers and writers of the Journal. Rather let me counsel those enthusiastic young people who enter so heartily into the adorning not to indulge in a display of gaudy banners and startling inscriptions, but to see whether they cannot impart to the interior of the sacred edifice a warm, bright, yet chaste appearance by a liberal use of Holly, mingled with Laurustinus, Ivy, *Arbutus*, and such other evergreens as may be had. Everybody loves to see the church under its familiar old Christmas guise, but few can really care to see there the tinsel and glare of a theatre. To gardeners who may be called upon to assist in church decoration and who then probably find themselves in the enjoyment of the, to them, not uncommon privilege of hints from refined ladies for the guidance of their work, I would say, Seize the opportunity to obtain a lesson in taste. Many a prosperous man owes much of his success in life to having turned such apparent trifles to account. Depend upon it your enjoyment of Christmas will be all the more hearty from the sense of knowledge gained and from the involuntary respect that is quite certain to be accorded for your demeanour under the circumstances.

But while preparations for Christmas must be conducted in various ways in a private manner, yet nowhere can the magnitude of the provision requisite for the coming festival be so fully appreciated as in the markets. To meet the demands of the Christmas week in the cities and towns of the kingdom other nations than our own contribute of their wealth. Oranges and Pine Apples from St. Michael's and other places, Lemons from Italy and Alexandria, Grapes from France and Spain, Melons from Portugal, Apples from America, Pears from the Channel Islands, and even Bananas from the West Indies, share in the Christmas cheer of British homes. Great, however, as are the consignments of these fruits, all of choice vegetables and

salads from foreign shores, they form but an infinitesimal amount of the requirements of the season in question. The great bulk, and an enormous bulk it is, of the Christmas requirements produced in gardens are produced at home. Those who have not seen the arrivals of produce by road and rail for the great metropolitan Christmas flower and vegetable markets can form no conception of their magnitude. Holly and Mistletoe are represented by stacks resembling ricks in a farmyard; "Christmas trees" by thousands—young Spruces from 1 to 3 feet high, and purchasable from 6d. each; vegetables of every kind, in quality of the first order and in quantity astounding; and flowering plants that startle the onlooker by their numbers and incite the envy of the gardener by their excellence of culture. This is an outline of the preparations for Christmas—the great festival of the Christian world. A pleasant thought arises therefrom—namely, that those who are engaged in the cultivation of the soil labour in an important field and share in noble work. Their toil may be hard, and in too many instances it is feared their immediate emoluments may be scant; but there is a great compensating after-pleasure to urge them on, for they make hearts glad and homes bright, maintain the high reputation of British husbandry, and honour themselves by the excellence of their work.—EWD. LUCKHURST.

HOW TO MANAGE AND USE RUBBISH.

RUBBISH heaps are a necessary appendage to gardens. There are daily additions being made to them throughout the year. Now it is the haul of a crop of Peas just past, of Lettuces run to seed, of Seakale or Rhubarb leaves which have done their season's work. Again, it may be the combined "pinchings" of the Vines of Grapes, and Melons, and Cucumbers, or an entire batch of faded softwooded plants no longer useful, or the pickings and cleanings of a flower garden, or the "cleanings" of potting sheds, the sweepings of roads or edgings of walk verges. In short, the rubbish heap is the receptacle for receiving everything connected with a garden of which no further use can be made at the time.

Now this gathering, which in some respects may be set down as a nuisance, is capable of being transformed into a valuable "gardener's assistant." There is, or may be, system in all things, and even in the matter of forming rubbish heaps it is profitable to do so systematically; accordingly all refuse of a woody nature—as prunings of fruit trees, stems of Cabages and allied crops, Jerusalem Artichokes, &c.—should be kept by themselves and burnt; stony mixtures also by themselves; and the main rubbish heap, composed of all refuse which decays quickly, by itself.

The commencement of the year may also mark the beginning of the year's rubbish heaps, and at that time be particular in forming the sites of the various heaps. The space required for combustible matter need not be large, as fires can be lighted at any time, and a bulky heap reduced to smoke and ashes; also, in the case of the stony mound, which never grows rapidly, the stones and soil are expeditiously separated by means of a sieve or screen. But with the heap of vegetable matter the case is different. As the summer progresses increasing quantities are daily added, and its bulk increases proportionally. Natural decay being not quite so speedy in its action as fire, the bulk of the heap does not grow less, but greater. Now, by having a system of throwing all such refuse neatly on the main heap as it is brought forward much inconvenient litter is saved, whilst the great body of matter is more favourable to the influences of decomposition than it is when scattered about. So much for the formation of the heaps. Let us now look to what use may be made of them.

During winter there are days which are only fit for working amongst rubbish, and on such days the vegetable heap should be turned over, shaking and mixing it well up in the process. Soil may be mixed with it as the work proceeds, also the ashes of the burnt refuse, but this is generally of as much or more value kept by itself. After this turning decomposition will proceed rapidly, and no further additions of fresh matter should be made to it. If on some day at the beginning of the succeeding winter it is again turned and left for a few weeks it will then have become a very valuable manure, rich in agents which are absent in ordinary stable or cowhouse dung. Where the latter manures are not over-plentiful the vegetable heap may with advantage be mixed with the dung.

In applying these heaps to the ground we like to have the whole intimately incorporated with the soil as the operation of trenching goes on. It invariably shows on the crops wher-

ever it has been introduced. As a manure for Peas, Beans, Artichokes, and Potatoes it is preferable to any animal manures; these inducing leaf and stem growth, whilst vegetable fertilisers act immediately on the fruit-producing portion.

As a dressing for Geraniums in flower beds decayed vegetable rubbish is also of great value, the tendency which animal manures have to induce leaf growth at expense of flowers being absent, as in the case of the Peas above mentioned. Where the compost is not decomposed and reduced so much as above recommended it should be worked into the bottom of trenches, and at the succeeding turning-over of the soil brought near to the surface.

There is an idea somewhat prevalent that the weeds produced from introducing refuse matter again into gardens counterbalance any benefits of a manurial nature. But there is no necessity to have any weed seeds in the heap. If weeds are allowed to reach the seeding stage before removal from the garden they should be burnt, as also anything calculated to render the compost of less value than it ought to be when properly managed.

The ashes remaining from burnt refuse are very valuable for dressing Grape Vine borders, Peach borders, and borders containing the roots of fruit trees generally. They are also used mixed with fresh soot for pointing into the surface of the soil for various vegetable crops, for which purpose they are very valuable.—R. P. BROTHERSTON, *Tynninghame*.

STRAWBERRIES IN WINTER.

WELCOME as are ripe Strawberries in early spring, they are equally esteemed during the autumn and winter months. We think the growing of this fruit for dessert during the period named will become general when it is known that fruit may be produced through October and November equal in flavour, size, and colour to fruit ripened in March. In the spring the Strawberry is forced in nearly every gardening establishment, but its cultivation for ripening fruit in the autumn seems confined for the present to only a few growers. At this season ripe Strawberries are regarded as a rarity, and are very highly prized by those who have them. We believe Strawberries can be grown all the year round, and would be better after Christmas than for two or three weeks before. The days begin to lengthen with the new year, and the increase of light and sun renders the ripening of the fruit better and easier than in December.

The supply of ripe fruit can be kept up from the time the plants have done fruiting outside if necessary. The time to start the first batch of plants for autumn fruiting very much depends upon the locality and the varieties that do best. In some places late varieties outside are a failure, consequently the season is very short, and if the supply is to continue an early preparation is needed to meet the demand. It is, therefore, necessary that the first batch of plants started to fruit in February and March are taken care of after the fruit is gathered, and gradually hardened off until they can be placed outside. These plants with good cultivation will again produce fruit if required in August. Later-forced plants will with similar treatment produce ripe fruit in October, November, and onwards.

We now come to another point, and not the least important—that is, the variety that will succeed best for our purpose; this we consider the first step to success, for we might prepare a quantity of plants ill adapted for fruiting in the autumn. Hitherto Vicomtesse Héricart de Thury has been considered the best autumn-fruiting variety. It has its good properties, and will certainly produce fruit at any season of the year; but this has been superseded by a variety we can recommend to give twice the quantity of fruit of large size, flavour and colour being excellent. We are indebted to Mr. Hinds of Otterspool for being in possession of such a valuable variety as Underhill's Sir Harry. If plants of this variety are forced in the spring, and after the fruit has been gathered the plants are well cared for, hardened off, and placed outside in a cool situation where they can receive a small season of rest, they will yield second crops of great value. While resting, however, they should be attended to in the way of watering. After enjoying a short season of repose they are ready to be partially shaken out and repotted into little larger pots, or be planted out in borders. Either system is good. Whether in pots or out they should be liberally supplied with water through the summer. This is all the attention they require until they commence throwing up their flower spikes, which

they will do freely in August. Those planted out should be lifted by the end of that month with good balls and placed in pots. After potting they are best placed in frames, kept close, well syringed and watered until they are established. When root-action has again commenced they should have plenty of air. The plants that were partially shaken out and placed in pots can remain outside until the end of September if the weather is favourable. It is best to place them inside after that date on vinery or Peach house shelves, as close to the glass as possible; there they will continue to bloom and set abundance of fruit, which should be thinned if large fruits are required.

The forwardest of these plants can be introduced into the Strawberry house, or where it is intended to fruit them. It is not advisable to introduce too many, because they will not afterwards stand retarding. The house should not be kept more than 60° at night to commence with, abundance of air being given on all favourable occasions. Care must be exercised that the internal atmosphere of the house is kept rather dry, which adds to the flavour of the fruit. If the weather is bright through October and November the flavour will be excellent. Other batches should be introduced as required.

The plants intended to fruit in January should be kept in a temperature of 50° to 55° at night, according to the external atmosphere, avoiding cold draughts. The flavour is not quite so good towards the close of December, especially if there is no sun. The small sample sent for your inspection were gathered December 11th; variety Underhill's Sir Harry. We have been gathering such fruit for some time past, and shall continue for some time to come, although during the past fortnight we have scarcely had an hour's bright sun. We would recommend anyone not in possession of this valuable variety to lose no time in obtaining it.—W. BARDNEY, *Norris Green*.

[The fruit received was perfectly ripe, of high colour and good flavour. The largest fruit was 4½ inches in circumference, and the smallest 3½ inches. Such fruit at this season is highly creditable to the cultivator.—EDS.]

FROST AND ITS MANAGEMENT.

THAT is a somewhat singular heading, yet I think there is a meaning in it—at least I thought there was once when I so managed it as to save a valuable store of early Potatoes. When injury is done by frost it is generally in the early part of the winter before we are alive to its full severity, or before everything has been prepared for a term of arctic weather. It was in November that my Potatoes were frozen. I thought they were safe, but was alarmed one morning to find them when moved "rattle like nuts," as my man remarked. It was a choice stock, and much esteemed both by my employer and myself. With these Potatoes I tried some experiments. Some of them I left unmoved and covered them with straw, but the frost increased and that lot was lost. Others I placed in cold water, and the ice formed on their surfaces immediately, and a great portion of the tubers "turned soft" and were valueless. The others, and just half of the bulk, I simply buried in the garden; not in a large heap nor deeply covered, but spread in a layer 2 or 3 inches thick and well beneath the surface. Here they remained until spring, when to my surprise and gratification nearly every tuber was sound, and grew as if they had never been frozen. That is what I call managing frost. I borrowed the idea from Nature, remembering that I had often dug up sound Potatoes which had accidentally been left in the ground all the winter, and which had not been covered more than an inch deep. Those tubers must have been frozen and recovered. In fact I had often seen—as others must have seen—a tuber partially embedded in the soil, the upper portion of the Potato exposed being frozen, the lower half in the ground sound. Twenty years have elapsed since I managed the frost in the manner described—managed to extract it from the Potatoes.

In the memorable winter of 1860 the frost, in spite of all precautions, found its way into the fruit room and turned half a ton of Apples as hard as stones. The Onions also were equally hard. Of the latter I had not much fear, but I felt certain the frost would ruin the fruit unless it was carefully managed. All the best of the Apples were buried the same as the Potatoes, and two months afterwards were dug up fresh and sound. They lost much of their flavour, but still they were of much service, and all were used for culinary purposes. Those left in the room—the smaller part—were utterly destroyed. A portion of the Onions was also buried, and all

turned out sound; but then only a very few were injured of those left in the room, which proved to my satisfaction how hardy Onions are when they have been well harvested and are kept dry.

As to the management of frost in the case of plants overtaken by it—I mean such as Geraniums and plants of a similar nature—I can only advise them being kept cool and dark until the frost is over and a general thaw has succeeded. I believe in the case of frosted plants that no better plan could be adopted than to dig a square hole in the earth, place a hurdle over it and cover it with soil, and then leave these cool dark quarters and leave the rest to Nature. I have had plants frozen and covered up in dark pits for six weeks together, and after the thaw they have been as green as when they were first covered up.

The above are a few instances of managing frost in a manner that was as valuable as it was successful; and I mention my experience now, when severe weather appears imminent, in case it may prove useful to others who may be placed in the same unwelcome position that I found myself in 1857 and 1860.—AN OLD STAGER.

ROSE RETROSPECTS.

As retrospects are in process I will venture to add my quota and cast one more pebble on the cairn of the old year. I do not think it will be remembered with much affection. It was a signal example of the impossibility of predicting. An early season may all at once become late, or a late season suddenly be transformed into an early one. In this year upon June 22nd, here in sunny Surrey there was hardly an exhibition Rose open in the garden, while in another week's time the whole Rose season was more than half over. The red Roses were overpowered by the tropical heat; the white Roses and Teas always take things more philosophically. To continue my observations: A bed of a hundred on Manettis, which had been over-excited at pruning time and afterwards went back greatly, now came to the front, and much strong and fresh new wood showed appreciation of the forcing weather. A showery summer materially assisted this, also a wet August was very favourable to budding. Far more buds started into little heads than usual. This, however, is a thing I by no means desire. I much prefer a bud waiting to shoot up into a strong single branch in the spring time.

From Briar cuttings this has been one of the best seasons I ever remember. I never saw the hedges so full of tall waving 10 and 15-foot shoots. And to my mind the Briar cutting is the coming stock. The stem is always straight; the roots it makes are wonderful. It takes one-fourth of the time to get into use of the seedling Briar, and it is infinitely more abundant than the Briar stock. Indeed so frequent have been the briarman's visits to hedges hereabouts that *Rosa canina* is in danger in some parts of disappearing.

With regard to Roses of the year—and every year has its Rose—Marie Baumann, as the election shows, queened it altogether. Of seedlings those two glorious Roses of Mr. W. Paul are certainly those which most dwell on my memory—Countess of Rosebery and Duchess of Bedford.—A. C.

THE STRAWBERRY—SYSTEMS OF CULTIVATION.

UNDER the above heading I detailed last June, on page 443, four systems of rooting runners for planting. I referred approvingly to the plan of rooting them in turves. I have made it my business to specially note plants grown in this way side by side with those grown by the other method, and the plants propagated from were in each instance the same, yet the disparity between them was most remarkable. Those former that had been raised in turves had splendid large healthy crowns with fine foliage, and will for a certainty produce some splendid fruit next season. The contrast with the lines put down from trowel-lifted young plants was most conspicuous. These plants being small and cannot bear a good crop of fruit for two seasons—a material consideration for those growers who pay so dearly for ground and want an immediate return.—W. J. M., *Clonmel*.

PETROLEUM AS AN INSECT KILLER.

I CAN corroborate Mr. Taylor as to the efficacy of this agent in destroying insects and not injuring plants. Nothing looks worse in the houses in a gentleman's garden than to see the axils and under side of the leaves covered with mealy bug or the young growths infested by red spider, or the leaves all

speckled over and looking rusty from thrips. Where such a condition of things unfortunately exists the cure for it is petroleum, or what I presume is the same, paraffin. In clearing a collection of plants from the insects named I placed five gallons of tepid water in a tub, and mixed with it (the mixing being as thorough as possible) about a quarter of a pint of paraffin. The small plants were dipped, the larger syringed. One man held the plant on its side over the tub and another gave it a heavy syringing, and thus the insects were killed and but little of the insecticide wasted. I syringed plants—some of them in flower—of Fuchsias, Geraniums, Poinsettias, Gardenias, Azaleas, Begonias, Gesneras, Hoyas, Ixoras, Lapagerias, Rhynchospermums, Coleuses, and Eucharises, and not one of them received the least injury to foliage, young shoots, or flowers. I have used the solution also for syringing Vines and Peaches, but not quite so strong, and nothing but good resulted, for all the insects were killed.—D. L.

PETROLEUM is recommended to be diluted with water, but the "mixing" is more apparent than real. For the purpose of a thin sprinkling the recommendation is all right, but the oil remains pure oil still; the water runs from the plants whilst the pure oil remains. The dose being repeated, in the course of time the leaf becomes coated with oil, the pores of leaves become clogged, and health disappears in the course of time. This was my experience with some Camellias I bought infested with scale.—J. WITHERSPOON.

SAVING A CROP OF GRAPES.

THE account recently given by Mr. Witherspoon of the dangers of using sulphur fumes in a viney induces me to relate my own experience in the same line as a further caution to amateurs.

In the middle of June, 1873, I planted a late viney with Vines struck from eyes the same year. The Vines were planted 3 feet 6 inches apart, and trained as single rods up the rafters about 20 feet. The viney is a lean-to facing due south, and the varieties are Gros Colman, Mrs. Pince, Lady Downe's, Aramon, and White Muscat. The back wall was planted with Hamburgs as a catch crop till the Vines on the roof came into full bearing.

Aramon was the first every year to show red spider, and this season about midsummer I noticed the first traces on it, and at once painted the pipes with lime and sulphur, and waited for a few days to see the result. The weather, which up to this time had been dull and cold, suddenly setting in very hot and bright, increased the red spider, and I therefore placed a pan of guano water under the affected Vine; but the continued drought favouring the spider, in a few days it began to spread to the other Vines, and as the Grapes were now stoning I determined to try and stamp out the pest with sulphur fumes. Fearing injury to the foliage I took special precautions against igniting any of the sulphur in the house; and on the evening of July 6th, having heated some flat pieces of iron in a dark room behind the viney, I sprinkled them with sulphur, and when quite satisfied that it was no longer alight I carried them into the viney. In this manner I succeeded in filling the house with a thin blue haze, and produced an atmosphere that no human being, and I fondly hoped no spider either, could long breathe and live. In about half an hour I looked in to see what effect had been produced upon the enemy, when I discovered that here and there the tender lateral growth was flagging, but as the main leaves were all right and the spider as lively as ever, I left it for another half hour or so, and then on re-entering I saw to my dismay that several of the main leaves were also flagging, and being now alarmed I at once opened the ventilators and soon cleared all the fumes out of the house. As soon as the air was clear enough to make a close examination it became evident that the foliage had suffered considerably, and I therefore left a little top air on all night, and went to bed hoping that no great harm was done. Awaking with the first streak of dawn I hurried down to see how much mischief had been done, and found every leaf curled up. For four years I had been cropping lightly to nurse my Vines, and your readers may judge for themselves of my disappointment at seeing my first full crop in such a sorry plight. What to do I did not know. There was no gardener in the neighbourhood that I could consult, and as the sun would soon be up it was necessary to take prompt measures to save the Vines; the crop I had no idea of saving, and indeed intended removing all the bunches

to ease the Vines. As there was no time to lose I at once proceeded to prepare some whiting and water, and syringed the roof till not a single spot of glass remained uncovered, so as to secure complete shade before the sun was up, and having shut up the house set to work to drench the borders and paths; and as soon as my man came I gave him orders to sprinkle water about every half hour or so, and on no account to open any of the ventilators. My idea being to keep the house as close and moist as possible, to force the lateral buds to break before the roots felt the loss of the foliage, and at the same time keep the leaves from drying up and falling off all at once.

In the course of the day I had time to examine the bunches, and found the Hamburgs on the back wall blackened in the berry stalks as if shanked, and apparently hopelessly gone. The late varieties on the roof were also blackened in the same way, but not so badly, excepting Aramon, the cause of all the mischief, and on second thoughts I resolved to leave the bunches on in the hope of saving a few.

As soon as the sun was fairly up the temperature rose to 120°; we sprinkled assiduously all day long, and fortunately the next day the weather turned cloudy and we were able to keep the temperature down to 90°. The leaves became browner and browner, but did not dry up. In three days the topmost lateral buds began to break, and in about a week three or four young leaves were formed. I then pinched out the points of these shoots to make the lower laterals break. After eight or nine days I noticed mould or mildew forming on the berry stalks at the point of junction with the berry, and gave a little air, besides dusting the bunches over with dry sulphur. The sun had not troubled me much during this period, but now shone out hotter than ever, and red spider soon re-appeared on the new foliage; but by the free use of the syringe and clear rain water I have managed to keep it fairly under. In a day or two after giving air the injured leaves dried up and fell off till not a score were left in the whole house, and these in every case were the first small leaf next the old wood.

In about a month the roof was covered with new foliage from the laterals, and the Grapes have since ripened remarkably well, in fact altogether beyond my most sanguine expectations. The Hamburgs on the back wall suffered most, and Lady Downe's lost a great many berries from scalding till the new foliage was sufficiently grown to shade them. Lady Downe's and Gros Colman when colouring cracked many of the berries at the point (which they have never done with me before, though Gros Colman sometimes cracks a little round the stalk), as I suppose owing to the elasticity of the skin being injured. Mrs. Pince and the White Muscat are almost uninjured. Whether the keeping qualities will be affected I cannot yet say, but they seem to hang all right at present, and I send you a few berries to show what they are like.

I have now lost all faith in the power of sulphur to cure red spider, and shall certainly not try it again. Judicious syringing with pure rain water is the safest remedy, and if carefully done will not injure the bloom—at least for all ordinary purposes, and for prize bunches the leaves can be sponged by hand.

Some varieties seem more liable than others to take red spider, and for this reason I shall not grow Aramon again; but the site and soil of a viney are, I think, of more importance, as in some situations with careful management red spider can be easily kept under, while in others it is a constant source of trouble. As prevention is always better than cure special attention should be given, whenever a spell of cloudy dull weather is succeeded by a burst of sunshine, to keeping the atmosphere of a house sufficiently moist and the borders thoroughly watered. Sprinkling the surface is no good, as the entire borders should be soaked right through, and with good drainage it is simply impossible to overdo it.—ESSEX.

[The Grapes received are excellent; the Muscats clear, Mrs. Pince's good, and Gros Colman fine, one berry exceeding 1½ inch in diameter—a worthy reward for the remedial treatment that was so intelligently and promptly applied under the circumstances.—EDS.]

SCHIZOSTYLIS COCCINEA.

I USED to flower this useful winter-flowering plant in pots, but latterly it has been found to succeed better left in the open ground, protection being afforded as called for by the state of the weather. This was provided by mats thrown over a temporary framework. Last winter the crop of flowers proved so

valuable that a frame with glass sashes was decided on for this and succeeding winters. It is a very plain erection—a sufficient number of sawn boards nailed on laths from the front, back, and ends; these are united at the corners with screws to allow for taking to pieces readily and storing away when not required. The sashes were part of the roof of a pit, which was reconstructed this autumn. Our stock is now, therefore, secure either from frost or heavy rains, which disfigure the flowers.

I find this plant does best divided every spring and replanted. The end of March is a good time to do this, pulling the clumps into pieces of three or four strong growths. These are planted 6 inches apart in rows a foot asunder. The ground requires to be well cultivated and liberally manured. The work during summer consists in keeping the bed clean and running the hoe occasionally up the rows. Treated thus the spikes are much stronger and the individual blooms larger than when allowed to grow on undivided and uncultivated for years. Our bed is 15 feet by 9, and is a little forest of spikes. The plants have been yielding flowers since the middle of October, and continue producing fresh spikes to take the places of those cut. In a cut state the spikes continue to open, though the colour is not so deep as when opened out of doors. By cutting portions of the stalks and changing the water twice a week the spikes last for ten days at least.—R. P. B.

WINTERING BEDDING PLANTS.

HAVING received several inquiries relative to preserving bedding plants in unbeated pits we reprint the following seasonable notes, as embodying the long experience of our accomplished old contributor the late Donald Beaton:—

The reason of hearing so much of harm in cold pits by frost and damp weather is just the want of Nature's rest for plants, and Nature's rest for plants is simply *cold* all the world over.

It is difficult, however, to cause Nature to rest in bedding plants during a muggy moist autumn, such as the last we have gone through. There was no real rest till the frost came on shortly before Christmas, and in many of the cold pits all over the country plants were in a very bad condition then to go suddenly to rest; and those who made and may make use of bright sunshine in hard frosty weather to help to keep off the frost will be punished in the long run if the winter holds on hard a long time.

Some people will lose plants from the sheer want of means of saving them from frost after all their good treatment; but the great bulk of the loss occurs from the soft state of the plants just before the frost, from the damp state of the bottom and sides of pits and frames, and the quantity of wet soil in the pots. Now the effect of an hour or two's sun on all this damp at this season of the year is to raise a strong degree of vapour, which, being confined, has the worst possible effect on softwooded plants. The moment the sun touches the glass of a cold pit in frosty weather air should be admitted, if ever so little, and the sun should be entirely off the glass before the air is shut off, no matter how cold the day may be. It is far better for soft plants to leave the glass wholly covered for days together in sunny weather during a hard frost than to raise that vapour inside a frame and not allow it to pass off instantly. With the exception of real practitioners it is difficult to make people to believe all this, for the mass of mankind do not and cannot see the immediate risk or any danger at present, nor signs of any such misfortune as is implied in these strict rules. But real practice has more effect on the public mind than the actual preaching-up of a theory, be it ever so sound; therefore just hear that I practise what I preach about my own plants at rest.

I have kept over three thousand Geraniums in one cold pit without any artificial heat. The pit is seventeen lights long in one division, the back is 9-inch brickwork, the two ends mounds of earth against 1-inch deal, and the whole length of the front is only of that material—or say, the front and ends of pitch-pine deal 1 inch thick; but there is a dry lining in front 6 inches through. The glass has a good slope, and is covered with four folds of mats, and as much stuff over them as keeps off any frost. During the slight early frost in October I closed this pit for two nights only, and then, expecting a run of mild weather, I fixed as a rule that abundance of air should be left on every night, and that the lights should be off, or all but off, the whole day if it did not rain till the glass fell to 30°. That rule applied down to the week before Christmas; then the first frost was 10° of cold, or the thermometer was down

to 22° on the scale, and some of the leaves got stiff with the frost after having two mats thick over the glass, but nothing to hurt; and I opened the lights wide while the sun was out, and in the afternoon I allowed the glass to get a little frosted before I put on the mats, which were also frozen a little.

The second change I had 14° of frost, the glass being down to 18°, and put four mats thick on. Then 12° of frost, and on the sixth night I put a deep covering of dry materials over the mats; and as long as the frost will last, even if it should be for six weeks, I shall not open this pit nor let the sun shine on the glass; but I am not yet sufficiently covered to hold out against a down-to-zero frost, and I shall add more to the covering or not according as the glass tells the fall of the temperature. After all that covering my glass is frosted just as on the first afternoon; the mats are also stiff, and all the materials over them are stiffish also, and the air round my pits cannot be much over 30° all this time; but I have no glass inside to tell how it is, and I am always afraid to trust to common thermometers that way, instead of the eye and the feel of a friendly hand among the leaves.

Now these plants are, at last, sent to rest entirely by cold, the most natural method of inducing entire rest. The pit is quite dry, and the longer I can keep the plants at rest the better for them and the easier for me. I shall keep them in the dark as long as the frost continues, and shall not open the glass till four days of thaw have passed, and then shall not open the glass till the first cloudy day, when I shall admit air very freely. Many years back I used to keep five thousand plants of Geraniums every winter, and I know of no better method for all kinds of frame plants. There is not a shade of difference between my present plan and that which I practised twenty years since; and I am convinced that the nearer the plan can be imitated the safer the plants will get through a long winter.

There is one other move, however, which helps me greatly—I never water any such plants the whole winter. They had not had a drop from the end of last September, and I hope it will reach to the end of next March ere they need watering. Hundreds of thousands of little Heaths, and others just as tender, and not over 3 inches in length, are kept in the London nurseries with only one mat to keep the glass clean, the rest of the covering being straw or stubble. But these being in very small pots must have occasional waterings, which doubles the expense over the plan of not watering at all; also doubles the risk of moulding or damping off.

The great error and the greatest danger are in the fidgetty ways of amateurs, who fear their plants are done for if they escape being uncovered for three consecutive days at a time. I think nothing of having my pets three weeks at a stretch as dark as the thickest covering can keep them. But where everything is wet or damp inside, and the alternate chills and vapours which are caused by every blink of the sun being used to keep up the heat render the plants so excitable, and so liable to the least cause of injury, that the wonder is how many of them escape a sharp winter.

NATIONAL ROSE SOCIETY.

THE annual meeting of the above Society was held, according to announcement, by permission of the Horticultural Club at their rooms, Arundel Street, Strand, on Thursday the 12th inst., the Hon. and Rev. J. T. Boscawen in the chair. There was a large attendance, including many of our best rosarians, and doubtless the inclement weather suggestive of no Roses but Christmas Roses deterred others from attending. Amongst those present were the Rev. Alan Cheales, Capt. Christy; Messrs. McIntosh, Davies, Jowitt, Mayo, Arthur G. Soames, Evans, Graveley, Yeates, Strange, Hart, Robins, Turner, George Paul, Cranston, Prince, Appleby, Young, Jefferies, T. Francis Rivers, Corp. &c.

The Hon. Treasurer, Mr. W. Scott, made his financial statement. It appeared that there had been £446 4s. 6d. received, and that there had been expended in prizes £366 6s. 6d.; in printing, stationery, and all working expenses £44 1s. 2d., leaving a balance in hand of £35 16s. 10d., there being, however, a debt due on account of the Exhibition at St. James's Hall last year of between £50 and £60; and a vote of thanks was proposed to Mr. Scott for the able manner in which he fulfilled his duties as Treasurer during the past year. The minutes of the General Committee having been read by Mr. Mawley the Hon. Secretary, Mr. McIntosh was elected as a Vice-President of the Society, and the Committee and officers were elected for the ensuing year, the local Secretaries being added to the list of the General Committee. An interesting discussion then took place as to whether any persons who were not members of the Society should be allowed to exhibit, and it

was ultimately agreed that non-members must pay an entrance fee of 5s., receiving also an exhibitor's pass. The Rev. H. H. D'Ombra, Hon. Sec., then read the correspondence he had had with the authorities of the Crystal Palace and Botanical Gardens, Manchester, when the proposal already made by the General Committee that one exhibition should be held on June 28th at the Crystal Palace, and the provincial one at Manchester on July 12th was ratified; a resolution, however, was added that efforts should be made to secure some other town for the provincial show of 1880. Another interesting discussion arose as to whether the highest number of blooms for amateurs should be forty-eight or thirty-six; and it was ultimately decided, after the pros and cons had been duly weighed, as Messrs. Baker and Jowitt would show forty-eight for Mr. Cranston's cup, thirty-six should be the highest amount required for exhibitors this year. The meeting was altogether a most excellent one, and much interest in the future welfare of the Society was manifested. The proceedings terminated with a hearty vote of thanks to the Chairman.

The annual dinner took place afterwards, when nearly thirty sat down to dinner, the Hon. and Rev. J. T. Boscawen in the chair, Dr. Hogg in the vice-chair. The dinner was excellently served, and some handsome dishes of Apples were kindly sent by Lewis A. Killick, Esq., of Mount Pleasant, Langley, near Maidstone; and flowers from Mr. T. A. Dickson of Covent Garden. With the exception of the usual loyal toasts none were given, the time being profitably occupied by a discussion on the best way of advancing the Society's interests; and a proposal was made by the Chairman that a die should be obtained and medals be struck off, to be given year by year to various provincial Rose societies. The idea was warmly taken up. Several subscriptions were announced, including those of the Chairman, Vice-Chairman, Messrs. Cranston, Paul, Robins, Hart, Oakes, and others. A vote of thanks was proposed by Mr. C. Turner to the Hon. Secretaries.

Altogether the Society may be congratulated on a very successful anniversary; and if, as was suggested, each member would endeavour to procure an additional one, the Society would be placed on a secure basis.

ICE HOUSES AND ICE STORING.

"ONCE upon a time," as the story books say, I had under my charge a large ice house. The well was excavated, or the greater portion of it, out of the solid rock. The perpendicular sides were as firm almost as adamant and nearly as smooth as marble. A portion of the sides, however, about one-third of the well, having been broken during the excavations, a lining became necessary, and for this bricks were employed. Thus two-thirds of the sides of the store were of stone and one-third of brick.

As all who have had experience in ice houses are aware, when the houses are opened in the spring, after having been closed for several weeks, it is found that the ice has shrunk from the sides, leaving a space all round between the ice pile and the walls. It was so in this case, but not equally so all round. In one portion of the house the space from which the ice had melted was usually more than a foot when the house was first opened, in the other only about 6 inches. If I were to leave the matter as it is and ask whether stones or brick walls were the better preservers, probably a few readers would find a difficulty in giving a correct reply. I will not, however, keep them in suspense, but will state that the brick walls were the best preservers of the ice, for it was there where the vacant space was always the most narrow. I was at first a little puzzled to account for this, but the reason for the difference came on reflection. Confined moisture in a state of vapour is the great enemy of ice keeping. Where ice melts there must be vapour, but a greater portion of the moisture, I presume, was absorbed by the comparatively porous bricks than by the closer and more impervious stone. If I were now lining an ice well I should line it with bricks.

In the storing of ice it is usual to place straw next the walls, but I cannot perceive the advantage of that practice. It is certain that much more air is admitted round the ice than when straw is not employed. This air melts the ice, and the melting causes the straw to become wet, and further waste must then follow. I have on more than one occasion placed straw half round the house, but never once saw the advantage of the practice, and it is now discontinued, and the room the straw occupied is now occupied with ice.

It is a common practice to pound or crush the ice as small as possible, and generally the practice is good, the object being to prevent air being enclosed in large interstices between large irregularly shaped lumps of ice. Where, however, the ice is strong and large sheets can be packed in layers, there is less air enclosed than when the ice is crushed. Thin layers of snow when it is actually frozen and quite dry may be advan-

tageously spread with the ice; but when the snow has a tendency to melt on being moved it should not be employed.

The first condition for keeping ice is a well-drained site, and the next a cool temperature with a dry surface to the pile. The latter can only be secured by ventilation enabling the vapour consequent on the melting of the ice to pass away. Ice houses after being filled should not be closed so long as severe weather continues; and even when the weather is mild and melting commences a little ventilation should be given occasionally in order to keep the atmosphere of the store as dry as possible. But however good the ice house may be, and whatever precautions are taken to preserve the ice, disappointment will result if it is not taken from clean clear water. If sticks, weeds, or leaves are floating on the surface of the water before it is frozen, and the particles become, as they must do, attached to the ice, then much money will be uselessly expended and labour wasted in filling the house, for such ice cannot be kept in any profitable and satisfactory manner.

It is most important that ice should be stored in all country places, for it is not only a great luxury in summer to the healthy, but is often a boon unpriced to those who are afflicted. By its timely application under medical advice ice has no doubt saved many lives; it is, therefore, incumbent on all who have the means of doing so to store ice largely, and store it well.—STEWART AND GARDENER.

ROYAL HORTICULTURAL SOCIETY.

DECEMBER 17TH.

THIS the last meeting of the year was rendered interesting by a remarkable collection of variegated shrubs, ornamental Conifers, &c., from the nurseries of Messrs. Charles Lee & Sons, and by extensive collections of Apples of considerable merit. Owing to the severity of the weather tender plants were sparingly exhibited, still sufficient flowers were staged to make the Council room cheerful.

FRUIT COMMITTEE.—Henry Webb, Esq., V.P., in the chair. Mr. Dancer, Little Sutton, sent Reinette de Caux and Dutch Mignonne Apples, and the Committee were of opinion that the two varieties are essentially identical. Mr. Moore of Warwick sent four varieties of seedling Apples. One, a seedling from Wyken Pippin, was a very handsome small dessert Apple of the size and shape of Golden Pippin. This was thought highly of by the Committee, but had been gathered too soon and had become shrivelled. Another raised from Bess Pool was also of excellent quality—tender in the flesh and of delicate flavour. These the Committee would like to see again. The others, too, were not thought to be an improvement on existing varieties. Messrs. W. Paul & Son exhibited a dish of Theresia Nevill Pear, a new variety raised by Mr. John Mannington, the raiser of Mannington's Pearmain Apple. It is of good size, rather irregular in shape like Ne Plus Meuris, of a fine firm buttery flesh, and delicate aroma with a rich flavour. This is a valuable winter Pear which will, no doubt, be heard of again. Mr. Killick of Langley sent a dish of an Apple called King William—a handsome, somewhat flattened, highly coloured Apple of very rich flavour, which was highly commended.

Sir Charles Strickland, Bart., reported on the varieties of cooking Apples that were submitted to his examination at last meeting. Dr. Hogg, raised by Mr. Sidney Ford, "very like the White Calville, probably a seedling from it. Melts perfectly, does not fall at all, juicy, slightly acid, very rich and sugary, delicate aroma. A first-rate baking Apple. If the tree should prove hardy, healthy, and productive, this will be a valuable Apple. I should like to try its quality later in the season." This was awarded a first-class certificate. Mr. Sidney Ford exhibited six dishes of Apples, to which a letter of thanks was awarded. Messrs. Ross, Coates and Co., Dunster House, Mark Lane, exhibited Apples cut in slices and dried, received from the United States. They preserved all the briskness and flavour of the fresh Apple, and were commended.

Mr. J. Douglas, Loxford Hall, Essex, exhibited bunches of Golden Queen and Royal Vineyard Grapes grown in the same house and under the same treatment, the object of which was to show the unhealthy constitution of the former, which had begun to decay in every berry, while the latter was quite firm and fresh.

Mr. G. F. Wilson, F.R.S., Heatherbank, Weybridge, sent dried fruit of Bananas, which were considered good as a sweetmeat.

Mr. D. Wilson, The Gardens, Castle Hill, South Molton, sent two very handsome Smooth-leaved Cayenne Pine Apples weighing respectively 8 lbs. and 7½ lbs., to which a cultural commendation was awarded. Mr. W. Iggulden, The Gardens, Orsett Hall, Romford, sent a dish of Trophy Tomatoes, to which a letter of thanks was awarded. Mr. R. Gilbert of The Gardens, Burghley, sent a brace of Taylor's Montrose Cucumber "Dispatch," to which a cultural commendation was awarded; also Cabbage Broccoli, which was awarded a first-class certificate for its high quality when cooked, the flavour being quite new in the Cabbage tribe.

Collections of fruit were received from Mr. Gardiner, The Gardens, Eington Park, Stratford-on-Avon, consisting of forty varieties of Apples and six of Pears, to which a silver Knightian medal was awarded; from Mr. Killick, Langley, Kent, thirty varieties of Apples, to which a cultural commendation was awarded.

FLORAL COMMITTEE.—Mr. C. Noble in the chair. The entrance vestibule was completely filled with Messrs. Lee's imposing collection of "hardy winter-bedding plants." Some of the "plants" were pyramid variegated Hollies 10 to 15 feet high, and standard Hollies, standard and pyramid Bays, Yews in great variety and of various sizes, some of them drooping, some pyramids, some table-shaped, some cones, some vase-shaped, a few of the common being grafted with variegated kinds, thus having golden heads. Some trees of the Golden Spruce showed to advantage, also Cryptomerias in various sizes, with smaller specimens of Taxodiums, Junipers, Thujas, Cupressuses, Retinosporas, and such-like elegant Conifers, amongst which were arranged with great effect standards of Euonymuses and Ives of the Arborea section—some green, others variegated. These were on stems from 2 to 4 feet in height, with compact heads about a foot in diameter, and were extremely ornamental. The collection was further relieved by Yuccas and several plants of Gynierum compactum elegans. Along the sides of the group were flat baskets artistically filled with dwarf plants, such as concentric lines of Retinosporas and Euonymuses, panels of plants of the same kinds; and some baskets contained masses of such plants as Ligustrum sinensis tricolor and Euonymuses edged with Box. This extensive collection embraced upwards of eighty species and varieties of shrubs and Conifers, all of which were in excellent condition, and attracted, and deservedly so, great attention. A gold medal was recommended for the collection.

Mr. Bull was awarded a first-class certificate for *Lælia anceps alba*, a charming acquisition that was described on page 449. It will find its way into all collections. Mr. Heims, gardener to F. A. Philbrick, Esq., Q.C., Avenue Road, Regent's Park, was worthily and unanimously awarded a cultural commendation for a fine example of *Sophronites grandiflora*. It was growing on cork, and had upwards of fifty brilliant flowers. The same exhibitor sent *Odontoglossum Warszewiczii*, which somewhat resembles a pale variety of *O. vexillarium*. Messrs. Hugh Low and Co., Clapton, were awarded a botanical commendation for *Masdevallia Trigloch*, a tiny plant with leaves an inch long and one-eighth of an inch in diameter, and equally miniature flowers. Mr. Green, gardener to Sir G. Macleay, Bart., Pendell Court, Bletchingley, was awarded botanical certificates for *Billbergia nutans*, with small drooping red flowers margined with purple; and *Grevillea fasciculata*. Mr. Green also exhibited *Æchmea Weilbeckii*.

Mr. Gilbert, The Gardens, Burghley, Stamford, sent plants of his double *Primulas* with large flowers in various colours and fine foliage. Most of them had been previously certificated, and only one variety, *Earl of Beaconsfield*, was honoured on this occasion with a certificate. The flowers are very double, $1\frac{1}{2}$ inch in diameter; petals slightly fimbriated; colour bright rosy magenta. The long stems of the individual flowers of these varieties render the pips valuable for bouquets. A vote of thanks was awarded for the collection. Mr. Smith, Ealing Dean Nursery, Ealing, exhibited about fifty plants of *Cyclamens* representing an excellent strain, the flowers being very fine, the whites pure, and the dark varieties rich, especially those ruby crimson in colour. A vote of thanks was awarded. Mr. Hepper, gardener to C. O. Ledward, Esq., The Elms, Acton, sent well-grown plants of *Solanum pendulum*, which resembles the old *S. Capsicastrum*, but the leaves have distinct light midribs. It is an elegant variety. A vote of thanks was awarded.

Mr. Cannell exhibited stands of cut Zonal *Pelargoniums* of wonderful excellence. The varieties were Henry Jacoby, Lizzie Brookes, Belle of Surrey, S. Holden, Dr. Denny, D. Thomson, M. Panton, The Shah, Mrs. Leavers, Mr. Pollett, Rienzi, Circulator, Kleon, Remus, Mr. Chandler, A. Henderson, Titania, Louisa, Miss Glastone, Mrs. Whiteley, Col. Seely, Lady Sheffield, and Mr. Palmer, all represented by grand trusses, and produced a rich effect. A stand containing twenty-four trusses of White *Vesuvius* was charming, and almost equally so was Salmon *Vesuvius*; the striped variety was also well exhibited. It is noteworthy that one pip of White *Vesuvius* had two bright scarlet petals, the other three being pure white. This was the finest collection of its kind that has ever been seen in December; in fact it would have done credit to any man at any season. A vote of thanks was worthily awarded.

Mr. George sent a seedling *Abutilon* Rose Queen, but it was passed by the Committee. Mr. Thomson, Crystal Palace, sent fruiting sprays of *Eucalyptus globulus*. Mr. Noble exhibited *Thujaopsis borealis* aureo-variegata; and an ornamental tin plant-suspender was exhibited by Mr. Peter Selby, 15½, Nuttall Hill, Birmingham.

The thanks of the Committees were tendered to the Chairmen and the Secretary, and the last of a successful series of gatherings during 1878 closed with a mutual interchange of

courtesies. Many of the meetings have been rendered additionally instructive by elucidatory remarks by Mr. Jennings the Assistant Secretary, and other gentlemen; and Mr. Barron and his assistants have exercised their usual assiduity in having the arrangements as complete as possible and convenient to all.

MANETTI STOCKS SUCKERING.

I HAVE received from Mr. Shackleton, Ireland, a plant of Charles Lefebvre budded on a Manetti with a decided shoot from a root of the stock and not from the stem. It is interesting to me as being the first I have ever seen, though Mr. Hinton says he has occasionally seen them; but I speak of it as a shoot, not a sucker, as the formation is decidedly different to that of the sucker of a Dog Rose or the sucker of a Raspberry or other plant that is accustomed to send up root suckers, which push the eye at the end of the underground root. The plant sent was budded on a healthy Manetti stock which had formed strong roots, and from one of the strongest roots a shoot has started as if a wood bud had been formed on the root. I am afraid some of your readers will think, that as I have always so definitely asserted that Manetti stocks did not send up root suckers but shoots from the stem, that I am prejudiced in making these remarks, especially as I have offered to cook and eat all true Manetti suckers; but I am obliged to acknowledge that the plant sent kindly to me has a decided shoot from the root, even if it is not a regular root sucker. It came by post and travelled very safely, and I have planted it with the Manetti shoot on it with the hopes of making further observations, and shall be glad if any other of your readers would kindly send me, if they find them when transplanting Roses on Manetti stocks, any plants that have either root shoots or definite root suckers.—C. P. PEACH.

MR. DOUGLAS'S RECANTATIONS ON DETAILS OF VINE CULTURE.

I VENTURE to trouble you with this communication because I think the *Journal of Horticulture* is the proper place for it, and also because I think it has a special interest for those of your readers who, like myself, remember what Mr. Douglas has written in your pages up till the end of last year, or rather the beginning of this. It is pretty well known that Mr. Douglas has altered his opinions on certain points of Grape-culture, though as yet the public do not know why. The fact only has been intimated that certain practices relating to Grape-culture which Mr. Douglas has all along recommended in your pages he now condemns. I was not, however, prepared for such a complete recantation, not to say a flat contradiction, of his own statements relating to matters of fact in reference to the said points as appears in the *Gardener's Chronicle* of November 30th, and with your permission I shall contrast his present statements and admissions in your contemporary with those which have more than once appeared in your pages from the same pen.

In the *Gardener's Chronicle* Mr. Douglas tells us that he thinks one "cause of exhaustion in early vineries is the custom of covering the outside and inside borders with fermenting materials." In the *Journal of Horticulture* only last year he says, on the strength of his past successful experience, that his practice of using fermenting materials "has always been successful." In the *Gardener's Chronicle* his experience of fermenting material is that it "heats violently for two weeks or less, and then as rapidly cools down." In the *Journal of Horticulture* for the end of 1875 we find him using a "thick coating sufficient to cause a gentle heat" only, and in the same passage stating that a coating of fermenting materials "1 foot or 18 inches thick will keep the heat for six weeks, when it may be removed." In the *Gardener's Chronicle* he states that the aforesaid "violent heat is not desirable, especially when the roots are near the surface." In the *Journal* he has no fear on this head at all, but rather doubts the heat from the bed penetrating the border, observing that, "although but little heat can be forced into the border by the heat of the fermenting materials, still it must warm it to the depth of a few inches." This was only the year before last. In the confession which Mr. Douglas reserves for another place, but which it was fair he should have made to his old readers whom he has for years so misled according to his own showing, fermenting material is all that is bad; it exhausts the Vines, it burns the roots, it is uncertain in its action, and it is altogether worse than useless.

In the "Doings of the Week" it is quite the reverse—highly useful, almost indispensable, and easily managed. He has himself been using the same for years with the most satisfactory results, and without a word of complaint.

I have heard a good deal of surprise expressed at Mr. Douglas's sudden and peculiar change of opinion by those who are familiar with his writings, and no wonder. The readers of the Journal need not, however, be disconcerted. What Mr. Douglas has there written is right; what he writes now is, in my opinion, wrong. He has espoused a cause that has broken down miserably at the outset, and unless he is prepared to tell us that what he has written under the head of "Doings of the Week" expresses neither his convictions nor his practice at the time, as they were supposed to do by every reader of the Journal, I doubt if he can furnish one single argument in support of his new opinions, from his own practice, as to the treatment of early Vine borders. Up to the beginning of the forcing season for 1878 (*vide the Journal of Horticulture* for December 20, 1877) he continued by his writings to profess unabated confidence in the use of fermenting materials, and but for an accidental remark dropped by him in conversation it is doubtful if the public would ever have known that the author of the "Doings of the Week" for years back had ceased to believe what he had himself so long taught confidently to others.

Mr. Douglas's conversion took place between last December and April of the present year, and it would be interesting, and no doubt instructive, to know what happened in that short interval to cause him to alter opinions based upon the highly successful practice of his whole past career as a Grape-grower.—J. S. W.

THE WINTER HELIOTROPE.

The plant that commonly bears this name is no relation to the sweet but tender Cherry Pie of the flower garden. It is only a humble Coltsfoot (*Tussilago fragrans*), and the more aristocratic name has been applied to it on account of its fine scent, which is very like that of the Heliotrope. In appearance it is a most unattractive plant, with coarse, roundish, toothed leaves, and before many of these appear it throws up a short stout spike or thyrus of whitish composite flowers; but, homely-looking though it be, scented flowers being at a premium in midwinter, a few pots of it will be found well worth their room. Its natural season of flowering in the open border is during the month of February, but if lifted in clumps, like Lily of the Valley, and potted in November it will flower by Christmas in a cool greenhouse, and a very little heat will force it into flower any time during the winter no matter when it is lifted, when it will be found very useful for mixing with cut flowers of a showier description.

It is a native of Italy and Greece, but has become naturalised in some parts of Britain. By the side of the Doon at Monkwood, near Ayr, it is very plentiful, and fifteen years ago it used to run riot in a belt of wood at Croxted Lane near Dulwich.—R. D. TAYLOR.

NOTES AND GLEANINGS.

ALTHOUGH a week of unmistakeable wintery weather has been experienced in the south, yet the FROST IN THE LONDON DISTRICT has not been nearly so severe as in more northern counties. The frost has varied considerably in intensity in localities. In Battersea Park only 10 degrees of frost have been registered, in Mr. Cutbush's nursery at Highgate 10 degrees, in his Barnet nursery 16 degrees, in Lord Londesborough's garden at Norbiton 9 degrees, and in Mr. Baring's at Coombe Cottage—half a mile distant—14 degrees. The most severe frost we have heard of near London was in Mr. McIntosh's garden at Dunevan, where 21 degrees of frost were registered. Only about an inch of snow has fallen in London, but south of the metropolis, in Kent, the ground has been covered about 4 inches deep. Yesterday (Wednesday) morning it was thawing in London, and some rain fell.

— REFERRING to our note on page 450 relative to the NATIONAL CARNATION AND AURICULA SOCIETIES, Mr. Dodwell assures us that he sent us the financial reports of the above Societies on November 23rd. Although these reports never reached us we do not doubt that they were duly sent as stated. Mr. Dodwell further adds that, "owing to deaths and the change always the work of time, though we start with a balance in each case in hand, yet without very liberal help

from new friends we shall inevitably be left with a deficit at the close of the season, and I appeal earnestly to those of your readers who love flowers and have means, to sustain us in the effort to give effect to the art involved in their development and in the wider knowledge well-sustained exhibitions confer upon an outside public. I am loth to refer to myself, but with seriously impaired health I have a double anxiety that associations which have undoubtedly elicited a wide-spread interest should sustain no interruption in their progress, and therefore I urge this appeal."

— AS Christmas trees choice, beautiful, and not common, few can rival ARAUCARIA EXCELSA. Small trees from 3 to 6 feet in height as grown in the different nurseries are handsome objects for room and corridor adornment at this festive season, and it is not surprising that such trees are in demand by the affluent as suitable Christmas presents among friends. These miniature trees are living presents, growing in beauty yearly in the conservatory, and have a distinguished effect when plunged in lawns during the summer. All the tender Araucarias are beautiful; some are massive, others slender; some quaint, others stately; but all without exception ornamental. A few very distinct are excelsa, Cooki, Cunninghamii, Rulei, and Goldieana.

— WRITING to us on RIPENING PEARS IN WINTER, a correspondent states—"If you want to have the fruit in the finest condition ripen it in a temperature of 80° to 90°, and keep it there as long as possible, so that it does not become icy cold before it is placed on the dessert table. There is no comparison between Pears ripened in a cold fruit room and others ripened in a warm stove. By placing fruit in a close box, and placing it in a Pine stove a week or ten days before Christmas, I shall have Beurré Diel, Joséphine de Malines, Winter Nelis, and Beurré Sterckmans in prime condition for the Christmas dessert; but if I left the fruit to ripen in the cool fruit room the only Pears I could place on the table would be Beurré Diel and Ne Plus Meuris, of second-rate quality. If you want to enjoy the full rich aroma of Pears, ripen the fruit in heat and eat it before it is cold."

— THE following seasonable note has been received from an experienced gardener on WORK FOR SEVERE WEATHER—"As soon as anything like a settled frost sets in and the ground is too hard for working it is common for men to be at once set to work amongst stakes and Pea sticks. This is often a mistake. So long as the surface of the ground is dry much soil moving, manure carting and wheeling, tree 'snaring'—that is, the removal and clearing away of large branches, can be done in the easiest and most economical manner; and such work as making stakes, Pea rods, pegs, &c., can be conducted during the thaw when it is impossible to work on the ground and walks often for ten days or a fortnight together. By a little forethought in arranging work it is surprising how fully and profitably men may be employed even during a long period of adverse weather. This hint is founded on experience—experience which included mistakes of the nature indicated, and which it will be well for others to avoid. Hence this note on the eve of what looks like an old-fashioned winter."

— WRITING from Tynningham on December 14th Mr. Brotherston observes—"We have had FROSTY WEATHER about a week, and 4 inches of snow has covered the ground for the last four days. Yesterday the frost held hard throughout the day, and by 11 P.M. the thermometer was at 9° Fahr., and fell during the night to 6.5° on the scale. To-day it has not been so cold. The barometer is about 29.9", but varies. To-day's *Scotsman* reports 12 to 18 inches of snow in the Kelso district, and the Tweed hard frozen. On the Cheviots over 2 feet of snow is reported. From 14° to 17° Fahr. is the lowest degree of cold generally experienced here, so that it may be concluded the 25.3° of frost we had last night will be exceeded in inland and high-lying districts."

— THE following is Mr. W. Bardney's mode of growing sticks of HORSE RADISH 2½ inches in diameter as detailed in "The Gardener":—"Now is a good time to lift the whole stock, which we would recommend to be done annually, and lay in some convenient place that portion of it that is fit for use. In lifting, the side rootlets should be selected for replanting. Cut them into lengths 7 or 8 inches long, and all the young fibry roots should be scraped off with the back of an old knife, and then be rubbed with a rough cloth, with the exception of half an inch at the bottom, which should be left to form roots when planted. After undergoing this scraping process they should be tied in bundles and plunged in coal

ashes, or laid into the ground with their top ends exposed until March, when they should be planted in ground that has been deeply trenched and well manured in rows 18 inches apart each way. They are best planted with a dibble, and the holes filled up with light soil, covering the crown about 2 inches. Treated in this way they will be again ready for lifting by the end of November. The small pieces planted in March will by that time be clean straight sticks, 6 or 7 inches in circumference."

— WRITING to us on the WEATHER IN DURHAM Mr. Witherspoon states that "On Thursday evening the 12th inst. the thermometer was down to 6°, or 26° of frost. Friday evening the same. Saturday at 7 A.M. the thermometer stood at 6° below zero; at twelve at noon in the sun we still had 22° of frost. There is about 15 inches of snow, and the hoar frost on the trees is remarkable, and in fact beautiful. The thermometer had risen up to 12° above zero at 10 P.M. on Friday evening. On Thursday evening the thermometer in Mr. Goldsmith's garden near here fell to 5° below zero, and on the snow it was 8½° below that point. On the morning of the 13th, Mr. Swan, of Newcastle, states that the thermometer was 3° below zero in that town. I had 14° of frost in my vinery, but the bulk of the Grapes were cut."

— THE "Journal of Forestry" observes that, "Whatever the immediate cause may have been, there appears to be a general scarcity this winter of the BRILLIANT BERRIES which usually adorn our copses and hedgerows at this dull period of the year. Holly, Hawthorn, Yew, and wild Roses are all equally void of their crimson berries, and we hear from the western counties that even the Mistletoe is affected with the prevailing deficiency, and not one 'bush' in ten possesses its usual quantity of delicate white clusters of berries. This is not a cheering prospect for enthusiastic decorators of homes and churches at the approaching festive season. Without a profusion of berried Mistletoe and Holly half the enjoyment and hilarity of the occasion is lost, and heavy evergreen decorations with nothing brilliant to relieve them only add dullness and monotony to the scene."

— MR. JAMES VICK of Rochester, N.Y., refers as follows in his "Illustrated Magazine" to AMARANTHUS SUNRISE:—"It is one of the most beautiful foliage plants we have ever seen. We have been cultivating it for several years in the hope that we might see its good qualities established. We have shown it at several State fairs, and no one plant we ever exhibited attracted so much attention as this." The coloured plate represents a dwarf plant of remarkably massive appearance, and having dark foliage, the growths terminating in brilliant heads resembling Poinsettias.

PROTECTING TREES AND PLANTS.

ONE of the soundest of many sound hints that are from time to time given in "Work for the Week," I regard as that stating that if the roots of plants are well protected it is surprising how much frost the plants will "endure." These words contain much truth, and no one can err by turning the suggestion to account. Next to the importance of protecting the roots of plants and trees against frost is that of protecting their stems. In many districts the frost is now severe and may increase in intensity. The safe plan will be to assume that it will do so, and then measures that are certainly prudent will be promptly taken to limit as far as possible its injurious influence. It cannot be safe policy to act, or rather sit still, on the assumption that the winter will pass rapidly away and that no special precautions are needed to counteract its effects. If the frost should only be temporary no possible harm can be done by any protection that can be given; but, on the other hand, if the winter should prove hyperborean in character, the wisdom of having taken the best steps to meet it will be apparent for a long time after the frost has passed away.

Haybands and straw wraps are cheap and easily applied. Let the former be placed round the stems of standard Roses, especially of any that are budded with new or choice varieties; also round the stems of Peach trees and standard ornamental evergreens, such as Rhododendrons, Bays, Laurels, and Hollies. It is the stems and not the heads of trees that are most amenable to injury—injury which by prompt preservative measures of the nature suggested may be easily averted. It is not many years since a severe winter almost wholly cleared wide districts of standard Roses. This was the case both in private gardens and nurseries, and the year following other Roses of the same kind

could only be obtained at high prices from the south of England or from France. Hundreds of Roses were then destroyed because their stems were killed, many of the heads having the shoots fresh and green, and only succumbed in the spring because the food supply was cut off by the destruction of the stocks. Many must have noticed numerous instances where the roots were alive and the tops also alive, but the stems black and dead. A few haybands would have preserved them, especially if the wrapping of the stems had been supplemented by tucking a wisp of hay lightly in the lower part of the heads where the wood had become brown and hard. It is the hard exposed wood of Roses that, for some cause or other, appears much more liable to injury by frost than the younger and greener shoots.

Many nurserymen appear to have taken a lesson from the severe losses that they experienced among their standard Roses during the winter of 1860, for since then it has not been unusual for them to take up their whole stock in late autumn and lay the Rose trees in, by "the heels," so that the heads, being close together, can be easily protected. Thousands of standard Roses are probably at this moment thus sheltered from the severity of the weather in various nurseries, and no one can question the wisdom of the practice.

Nurserymen also are not deterred by a little extra labour from wrapping the stems of valuable ornamental trees with hay or straw bands, and owners of cherished specimens, and gardeners, may well follow their example. The cost of such a practice is trifling, and may be repaid fortyfold by the preservation of trees or shrubs that cannot easily be replaced. Any tree, &c., of doubtful hardiness should be protected in some way or another. It does not so much matter what the protecting material may be, the point of real importance is to apply it promptly. The stems of Vines should not be forgotten where any are exposed between the ground and their point of entrance into the house, but all such should be encased in haybands. A few stakes, and rough—the rougher the better—straw bands may be easily arranged so as to save the life of any somewhat tender Conifer or other lawn ornament, and more lowly plants and crops may be protected by dry fern, evergreen boughs, or litter.

Snow for such crops that it can cover is the best of all protectors, and when it is present men with shovels may be usefully employed in placing it where it may be needed, only moving it, however, when it is in a dry powdery state. I have often saved Lettuces, Cauliflowers, beds of autumn-sown annuals, and other flowers by protecting them with the covering that Nature has provided. Frames, too, covered with mats or straw may with advantage to their inmates have a further covering of snow. Hundreds of such plants as *Calceolarias*, *Intermediate Stocks*, *Pentstemons*, and plants of a kindred nature may be saved with the aid of snow, and I cannot too strongly urge those who have the opportunity to adopt that practice.

During the past few years the winters have been unusually mild, but on that account we must not be lulled into a sense of security that may prove false. The mild winters may only prove a prelude to weather of corresponding severity, just as violent storms and inundations often succeed periods of prolonged drought. According to the compensatory law of Nature severe winters are now due; let us, therefore, prepare for them, and then if they do not come so much the better.—A NORTHERN GARDENER.

OUR BORDER FLOWERS—SYMPHIANDBRA PENDULA.

THIS charming Bellflower is from the Caucasus, and is too rarely met with in collections of border flowers. It is closely allied to *Campanula*. It is a very attractive plant, its creamy-white flowers being very handsome, to say nothing of their peculiar form. The plant grows little more than a foot in height, the flower stems terminating in drooping spikes. It is a superior plant for the front row in the herbaceous border. It is all the better for having partial shade afforded it. Under some circumstances there may be some difficulty in succeeding with it, but when its requirements are supplied it affords a grand display on a moderately moist partially shaded rockery during midsummer, and continues in bloom for a length of time. It is a fine plant for exhibition; easily increased by division, which is best done after its flowering. A surplus stock should be kept, as the plants will sometimes disappear unexpectedly. They thrive in a compost of good sandy loam, peat, and well-decayed vegetable matter in equal quantities,

with a sprinkling of coarse grit and charcoal dust, made firm in planting.—*VERITAS*.

CAPE HEATHS.—No. 12.

DECEMBER.

IN these our concluding notes upon *Ericas* we have introduced a few elegant but much-neglected species without at all taking into account their time of flowering. They are not kinds that are chosen by those who grow for exhibition purposes; but we venture to assert without fear of contradiction that all would be welcomed by any amateur who seeks to adorn his greenhouse with beautiful and interesting flowers. It has been written of the amateur plant-growers that they "do not care for Heaths," but our own experience and observation directly contradict such an assertion, for we never heard this remark from either sex. True, many have been deterred from entering upon their cultivation by the bugbear which is always thrown around these beautiful plants by many professional gardeners, who tell their amateur friends, with such a profound look and mysterious shake of the head, that *Ericas* are so very difficult to grow and they will never succeed, but we would urge our amateur plant lovers to try them. We acknowledge and know full well there are difficulties attending their management, and so there are with all other plants more or less; but there is no secret about the growing of Heaths that cannot be mastered; and for general directions we should say, Drain your pots thoroughly, pot firmly in good sweet peat soil, do not add too much sand as it only impoverishes the soil, do not overpot, water freely but judiciously, keep a free and dry atmosphere about the plants, and should mildew show itself immediately apply the remedy we have already given. Plants treated in this manner will, however, not suffer much, if any, from this disease. Other and minor details in their management will suggest themselves to those cultivators who look upon the attentions their pets require as a labour of love, and their care will be rewarded by a rich return of beautiful flowers, which last long in full beauty, and the like of which is not to be obtained from any other genus of plants.

Fig 69.—*Erica Banksiana alba*.

Erica Banksiana alba (fig. 69).—A dwarf-growing pretty plant, having a beauty entirely its own. Leaves arranged in threes, dark green. Flowers terminal upon the small branches, produced singly or in pairs; calyx imbricated; corolla long and cylindrical, white; stamens long, much exserted and brown, and add much to the general effect.

E. lutea.—A dense-growing species. Leaves small, linear, and quite smooth, light green. Flowers mostly in pairs, soft yellow, produced in the greatest profusion on the points of all the little branches.

E. halicacaba.—This we cannot recommend as a very showy species; nevertheless it is a most interesting kind, dense and branching in habit, with long and closely-set dark green leaves. Flowers pendant, large, and inflated, pale yellow.

Fig. 70.—*Erica buccinaeformis*.

E. buccinaeformis (fig. 70).—Elegant, somewhat slender-growing. Leaves linear, closely set, soft green. Flowers mostly in twos and threes, long and tubular, rosy red tipped with green; stamens exserted.

E. moschata.—An erect-growing species with slender branches, and short linear light green leaves. Flowers in threes or fours, large, ovate, with a suddenly contracted neck and recurved limb; pale yellow, yielding a Musk-like fragrance.

E. urceolaris.—Leaves long, arranged in threes, dark green. Flowers in umbels, erect, white, and borne in great profusion. A very ornamental plant.

E. purialis.—A dense-growing much-branched plant, with broad, short, bright green leaves. Flowers globose, mostly in threes, rosy purple, and produced in such profusion as to give to each branch the appearance of dense umbel.

E. Sebana rubra.—The varieties of *Sebana* are most interesting, eccentric in shape, and with such sad combinations of colour they rivet the attention of the most obtuse observer. They are strong-growing plants and profuse bloomers. Leaves dense, mostly in threes, linear acute, dark green. In the present variety the large calyx is straw colour; corolla cylindrical, deep red; stamens much exserted, chocolate brown.

E. Sebana fusca.—In this variety the flowers are longer than in the preceding, and the corolla differs in being a pale brown.

E. Sebana lutea.—This differs in the corolla being yellow, otherwise it resembles in habit and appearance the variety *rubra*.

E. barbata.—A very distinct and ornamental species. Leaves large, ovate, arranged in fours, dark green, and profusely furnished with long hairs. Flowers urceolate, hairy, white, produced in umbels terminating all the branches.

E. fragrans.—A slender-growing elegant little plant. Leaves linear, smooth, arranged in threes, light green; calyx large, same colour as the flower, which is ovate, mostly in pairs, on the ends of all the branches; light purple if exposed to the air, but white indoors. Delicately perfumed.

CENOTHERA TARAXACIFOLIA.

THE Dandelion-leaved Evening Primrose is of prostrate but not very compact habit, and is highly ornamental. The flowers

are large, pure white at first, but afterwards changing to pale pink or rose. It is eminently a night-bloomer, few flowers being found expanded during the day, but in the twilight

every plant seems covered with great saucer-like discs 4 or 5 inches across. Not being fastidious as to soil it is easily cultivated, and can be increased by careful division of the roots

Fig. 71.—*CEANOTHERA TARAXACIFOLIA*.

in spring. Seed also germinates easily if not old, and a stock is best raised by this method. Not being very neat it is best planted where it can ramble at its own will on the rougher parts of the rockwork, or in some roomy border where extreme dressiness is not looked for. It also shows to advantage when

used for surfacing large beds in which tall plants of erect habit are grown, as Roses, Dahlias, scarlet Lobelias, &c. Flowers from July to the end of September, continuing onwards occasionally until nearly Christmas in southern districts and in mild seasons. This good old plant used to be more extensively

cultivated twenty years ago than it is now, but there are signs of its returning to public favour. Native of North America.—R. D. TAYLOR.

CUCUMBERS AND MELONS.

"BOTH Cucumbers and Melons are given to degeneration," is a remark often heard and seldom contradicted, but the cause of the evil does not appear manifest to all. Is it not a consequence of in-and-in breeding? A variety impregnated wholly by its own pollen for several consecutive generations results in enfeeblement of constitution and a consequent depreciation of produce. This is, I think, incontestable. Plants can only be kept healthy and capable of producing a maximum of produce of the greatest value by the introduction of fresh blood. In all crops there are degrees of excellence. To save seed from the superior plants is to secure a progeny of similar superiority, tending to still further improvement; seed of inferior plants affording plants correspondingly inferior. Negligence in the selection of parts for the continuation of plants leads also to degeneracy, as does also inferior culture, superior culture affording in many instances "sports" superior to the originals.

Whatever is lost by in-and-in breeding may not in all instances be restored by fresh pollen, but much may be done by impregnating a weak plant with the pollen of one showing undue vigour; the progeny will then be invigorated. Health and disease in plants are as much promoted by weakness as by grossness arising from poverty of culture on the one hand and high culture on the other, and those results are transmitted by the pollen. A variety inherently weak cannot be restored to vigour without a change of blood, and the nearer the species is approached in obtaining it the greater will be the vigour implanted in the progeny.

Cross-breeding has been carried out to such an extent in Cucumbers, also with Melons, but not to nearly the same extent with the latter as former, as to be little less than in-and-in breeding owing to the slight variations in the plants operated with. The object in raising new varieties appears to be size, everybody seeking to have fruit longer than somebody else. No matter how gross a variety may be, it must be crossed with another variety equally gross with a view to the securing of long Cucumbers. The questions of flavour and fruitfulness appear to be ignored, the chief aim apparently being the production of big Cucumbers and monster Melons. Cucumbers and Melons producing large fruits are generally shy bearers, which shows that large stature and robustness result in constitutional sterility. This accounts for high-bred Cucumbers being shy seeders, and suggests the necessity not only of care being taken to keep the variety true, but of experiments being made to cross it with a dissimilar yet desirable variety in the hope of obtaining a fresh variety that will supplant both parents. In-and-in breeding may be carried to an extent frustrating the all-important object of reproduction, but comparatively sterile plants may usually be made to produce seeds by fertilising them with pollen from some of the more original types of the species. The more constitutionally hardy the female parent is the finer is the offspring. Therefore, in crossing Cucumbers or Melons robustness in the female should always be selected to impart any desired vigour to the progeny, and *vice versa*.

If a green-flesh Melon, say Beechwood, be crossed with a scarlet-flesh—Read's for instance, it does not follow that the progeny will be all after the male—*i.e.*, scarlet-fleshed, but a majority of the issue follow the male with some increase in the size of fruit, but the minority following the female are marked by still greater robustness of plant and increased size, and more prominent netting of fruit. This points to the wisdom of selecting robust hardy plants as seed-bearing parents, and high-bred plants for males. The former will tend to increase grossness and concomitant barrenness, not perhaps in fruitfulness but in seed-production, with no improvement of constitution.

The crossing of Scarlet Gem Melon with Little Heath would not add anything to the constitution of the former; but cross Cantaloupe with Scarlet Gem, or Rock with Colston Basset, and a marked improvement is produced at once in the constitution of the progeny. By crossing this progeny with Moreton Hall or Read's in one case, and Pine Apple or Golden Perfection in the other, improved flavour is approached with a certainty; yet every approach to flavour results in the diminishing of the size of the fruit, for whatever may be shown to the contrary by the number of seedlings certificated of late years, I submit that there is not only an advance in size but a decided increase of

coarseness of flesh, with a lack of firmness or crispness of flesh and briskness of flavour. A majority of our present race of Melons are flat, lacking the tender melting flesh and sprightly perfumed flavour of such kinds as possess them in the highest degree—*viz.*, Egyptian, Pine Apple Gem, and Scarlet Gem. I shall possibly be considered as being extremely prejudiced against innovations. The fact that existent varieties are speedily superseded by seedlings is proof conclusive that their merits are of a transitory character. Without an influx of fresh blood the variety, whatever it be, soon begins to degenerate, and can only be kept up to a high standard by careful selection and superior culture.

By directing attention to the wearing-out of old varieties my object is to direct attention to, and to suggest a remedy for that fell disease so fatal to Cucumbers and occasionally Melons. Of the disease I have had no experience, which I think is solely attributable to my practice, adding the new varieties as they are sent out and discarding the old, therefore operating only with fresh blood. What I have seen of the disease leads me to form the opinion that it is due to high breeding and repeated impregnation with pollen from the same plant. I have repeatedly noticed that with a plant having the male and female organs in the same flower the potency of the pollen is more decided from another flower on the same plant, and more decided still in that taken from a different tree. The pollen of a weakly blossom is in effect very slight upon the pistil—often inert; but the pollen of the weakly blossom is more potent applied to the stigma of a gross blossom of a very vigorous tree, the pollen from the latter acting advantageously on the weaker blossom of the other tree. Weakness on the one hand and grossness on the other are thereby modified. In crossing Melons and Cucumbers I have noticed a similar coincidence. Very vigorous plants have corresponding blossoms male and female, and are not readily impregnated with pollen from the same plant, such plants being bad setters, a weakly plant not always setting fruit freely. In both instances foreign pollen generally secures a good set, and the nearer it is obtained to the species the more marked is the improvement of constitution of the progeny, increased hardiness as well as seed-productiveness being promoted.

The constitution of Cucumbers has been so weakened by in-and-in breeding as to result in barrenness, many of the high-bred sorts seeding very sparingly, some varieties not being continued true except by cuttings. If I am warranted in the foregoing deductions, which are the results of experience, constitutional vigour can only be restored by a return to a parent nearer the species. We have, it is true, no want of luxuriance in the plants that give fruit comparable in size to hedge stakes, but such fruits are limited in number and produce few seeds. We have, too, varieties affording useful fruit plentifully, but these for the most part of the Sion House type have constitutions little better than the large-fruited class, and both types may be improved by judicious crossing.

I have had the pleasure of trying three varieties all with admirable constitutions. They were kindly sent to me by the raiser, Colonel Taylor, Montrose, Weston Park, Bath. This gentleman, acting on the idea that fresh blood only was required to restore the constitution, selected Lord Kenyon's Freebearer as the female, with, I think, Sion House as the male parent, the result being a hardy frame Cucumber 12 to 18 inches in length, with a short neck, deep green in colour, with few spines, remarkably free-bearing. It is superior to any variety of the same type in hardiness, productiveness, and quality. It is named Montrose Seedling, coming nearest to Duke of Edinburgh (Munro's), but superior to that kind; in fact I consider it the best of the everyday Cucumbers for every purpose. It succeeds well in a frame without heat after the middle of May.

No. 2 is from Lord Kenyon's Freebearer crossed with Duke of Connaught (Sutton's). In this we have the constitutional hardiness of the female parent, and a fruit as near between the two parents as possible, not a little of the vigour of the male being imparted to the offspring. It is not so hardy as Montrose Seedling, not doing so well under frame culture, but is a paragon for house work, and will prove a powerful rival to Telegraph, which it much resembles, but is of much better flavour. It has a short handle, is straight and even, in shape like a gun barrel, deep green in colour with blue bloom, carrying the flowers well and with few spines, with length enough for the most fastidious, and a shy seeder.

No. 3, Montrose Seedling crossed with Duke of Connaught. In this variety we have the hardy constitution of the female without any of the grossness of the male parent, the free-bear-

ing property of the female, and a fruit of the size of the male 20 inches and more in length, short neck, regular in thickness, few spines, deep green skin, very handsome, and very good. It succeeds admirably under frame culture, and is only a little less hardy than the ridge varieties. Such a valuable trio seldom fall to the lot of a raiser at the onset, which shows that proceeding upon the principle of selection is preferable to the haphazard system of crossing, which results in varieties the merits of which principally rest upon the superior culture bestowed upon them so as to bring them to perfection.—G. ABBEY.

HEATING BY PARAFFIN STOVES.

I USED a small stove all last winter and it never harmed any plants in the house, and my house contains a great variety. This year I made a larger stove from the plan of your correspondent "E. H." at page 261 of this Journal for this year. It stands 21 inches high, and is 6 inches in diameter and holds one quart of oil. The oil I burn is 1s. per gallon, and I was able to keep up the temperature of my house (a lean-to 10 by 7) to 42° during every night this week, without any covering over the house, even when there has been from 10° and upwards of frost. I keep the wick trimmed, fill up the oil once a day so that the lamp may not burn out, and keep the lamp turned up to one height.—F. W.

[Our correspondent "E. H." has informed us that he has succeeded perfectly with a bed of Melons raised and ripened entirely with a paraffin stove for supplying artificial heat.—Eds.]

NOTES ON GRAPES.

I FOR one would like to see the character of every Grape in cultivation discussed in the *Journal of Horticulture*. That such a discussion would prove interesting to all and instructive to many there need be no doubt, as there is no plant cultivated under glass to which so much attention is paid at the present time as to the Grape Vine. To set the ball rolling in the matter suggested, I will state my experience with a pretty extensive collection of Grapes.

It has often been asserted that Black Hamburgh and Muscat of Alexandria are the two best Grapes in cultivation. In this I fully coincide, especially in the case of the Hamburgh; but the Muscat is only a Grape for those experienced in Vine-growing, as it will not do well with either the ordinary attention or the moderate temperature sufficient for the Hamburgh. In these respects it is not the best white Grape; with plenty of heat and good management it is.

Respecting many new Grapes I think they are like many new boilers, which make their *début* as being something to surpass everything else, but in a year or two they are heard little of. I believe Pearson's Golden Queen an exception to the above rule. I have grown it since its very first appearance in public, and I know of many others who have done the same; and in every instance it has given perfect satisfaction. Amongst its many good qualities, one of its greatest is its hardy constitution and the very free way in which it grows. It is just the Grape, I should say, that would do admirably in an unheated house, and in such a house I mean to try it. Briefly, it grows well, forms fine-shaped bunches, sets well, ripens thoroughly without any trouble, becomes of a splendid golden colour, is of excellent flavour, and lastly it keeps intact when others around it can hardly be kept from decaying.

Madresfield Court is still sustaining the good character it showed at first with many growers. It is a Grape well worth growing to supply fruit from July to October. It has handsome bunches and berries, and fine flavour. It has also the means of growing well; and without this tendency Vines are next to worthless. I have never found it showing any inclination to decay as it has been said to do with some cultivators. What has become of Waltham Cross Seedling Grape? I had it when first sent out, but the berries showed such a tendency to decay before it could be used that I have not had it for some years. Information on this Grape is wanted. Let me put the same question about White Lady Downe's. This Grape was to take the place of all other late white Grapes; and wherever there was a house filled with Black Lady Downe's it was expected that the half of them would be rooted out to give place to the White, then there would be a supply of Grapes in two colours as late as anyone chose to keep them. Has this come to pass? Not that I am aware of. Indeed I cannot name a place where White Lady Downe's is cultivated, and

my acquaintance with Grape-growing places is not very limited. I saw the Grape some years ago, and then did not consider it either good in colour or flavour, and it had a bad habit of producing small stoneless berries. Black Lady Downe's is not altogether free from this defect. Its late-keeping quality is the best property this Grape possesses. Its thick skin is not pleasing, and on this account it is not being quite so generally planted as it was. Gros Colman is one that is taking its place a good deal, and its thin skin and fine appearance qualify it for its position. With us it has always been best when it was ripened in September and used from the middle of November onwards.

Dr. Hogg and Duchess of Buccleuch are about very similar as regards merit. The Doctor is the most to be preferred of the two, as it is of equal flavour and never shanks nor cracks. These and the Grizzly and White Frontignans might all be classed together for small size of berry and fine flavour.

Buckland Sweetwater is a Grape seasonable from May until November, with qualities much above the average. It does not require much heat; bunches and berries large, colour good, flavour fine. Foster's White Seedling possesses the same character. Golden Hamburgh is more tender and less worthy; ditto Golden Champion; and I can give no better verdict about Duke of Buccleuch.

Gros Guillaume is a fine winter Grape when it colours well; and to insure this it must not be overcropped. Black Alicante is a useful, easily managed, free-fruited late Grape, which, I presume, no person can say much against. Calabrian Raisin and Trebbiano are both useful late white Grapes, superior to Syrian, Royal Vineyard, Muscat Eschollata, or Tokay; but the latter may be placed after Trebbiano. Mrs. Pince is a good late black companion to the Alicante. Venn's Black Muscat I take to be the same as my Muscat Hamburgh, and neither of them is worth planting more than one cane of at the most.

At the present time my selection of the most useful Grapes would be for from April to October—*Black*: Black Hamburgh, Madresfield Court. *White*: Buckland Sweetwater, Foster's Seedling. From October to April—*Black*: Gros Colman, Alicante, Gros Guillaume, Lady Downe's. *White*: Pearson's Golden Queen, Muscat of Alexandria, Calabrian Raisin, Trebbiano. To be planted in proportion to the order in which they are named. Half a dozen good early and late Grapes are often more serviceable than three times as many different varieties.—A KITCHEN GARDENER.

NOTES ON A CONSERVATORY.

THE fine large conservatory adjoining the residence of Colonel Lloyd, Lillesden, Hawkhurst, is at all times worthy inspection, and especially so during the late autumn and winter months. The site itself is very good, commanding as it does a view of the fine undulating pleasure grounds in which it is situated, and also one of the many bits of picturesque scenery for which Kent is famous. It is a plain rectangular building with a three-quarter span roof. Two large beds are in the centre, and a narrow staging runs round the front of the house, which is usually kept filled with florists' and other flowers interspersed with foliage plants, and fringed with *Isolepis*, *Lycopodium*, *Panicum*, &c. The beds are filled with specimen Palms, Ferns, *Dracenas*, *Camellias*, *Abutilons*, and other choice foliage and flowering plants. *Yucca aloifolia variegata* is well grown and in good numbers, and is a fine decorative plant. The *Camellias* mostly planted out were remarkably healthy and well set with buds, some flowers of *Alba plena* being already expanded. Mr. Channing, the able gardener there, uses the knife freely among *Camellias* should any of them be at all unshapely, and others would do well to follow his example. Among the above were interspersed well-flowered standard *Chrysanthemums*, standard *Pelargoniums* (a good way of growing this class of plants for similar work), *Celosias*, *Salvias*, &c. The plants are all well grown and of good shape, consequently there is no necessity to arrange them closely to hide defects, which is too often the case in many conservatories. A good margin of *Lycopodium denticulatum* is planted round the house, with the exception of the ends. These are filled with *Sedum acre elegans*, and in this is dotted a double line of *Nertera depressa*. These were well berried, and we never saw them used with better effect.

The pillars and girders are covered with climbers, which are always well managed at Lillesden. *Habrothamnus elegans* will be a beautiful sight at Christmas, and a good-sized plant of *Bougainvillea glabra* trained up the back wall and on to the roof was flowering profusely for the third time this year, the colour

for the time of year (late in November) being very good. On this same wall was a healthy plant of *Luculia gratissima* which promises soon to flower abundantly, also *Camellias*, *Heliotropes*, *Pelargoniums*, &c., which materially contribute to the supply of cut flowers. To use with these, *Adiantum cuneatum* and *for-mosum* are grown in large numbers, some of the plants being very large indeed, and of course are equally useful and effective used among the other plants.

One of the vineries at the time of our visit was filled with *Dendrobium nobile*. There were plants of all sizes, all alike giving promise of freely blooming whenever introduced into heat; and what is more useful than this *Dendrole* where there is a demand for choice cut flowers? Mr. Channing's very successful mode of treating these plants will be given in another number of this Journal.—W. IGGULDEN.

NOTES ON VILLA AND SUBURBAN GARDENING.

THE weather must in a great measure decide the operations to be performed in the kitchen garden department. Should the frost continue severe it will be necessary to give an extra coating of protection to pits and frames; the lighter and drier the covering is the less will the frost take hold of it. Celery should be covered with bracken or other litter, for if the leaves and top of the stalks are frozen the decay will spread downwards and do great injury. Seakale, Rhubarb, Artichokes (Jerusalem), and Parsnips should also be covered with litter, which not only protects them from being injured by the severity of the weather, but enables them to be easily lifted for forcing or culinary purposes.

Prepare fermenting material for hotbeds by mixing with the leaves collected some long stable manure. This should be well shaken out and thoroughly mixed with the leaves and left massed together until it is wanted for use. Such a heap is valuable for forcing of Potatoes, Carrots, Radishes, or for the making of a bed for Cucumbers. Potatoes stored away either for seed or for the supply for the table ought to be looked over for the removal of any diseased tubers, and the store must be sufficiently protected from frost.

The pruning of all kinds of fruit trees and bushes may be completed if the weather is not too severe. A little frost renders the ground clean for the operator, but we prefer warmer days as a rule for pruning, yet where there is much of such work to be done it is sometimes necessary to do it during the cold winter days. Peaches and Nectarines on walls may be left until the early part of the new year, when it is advisable to unfasten them and allow them to remain from the walls as long as it is possible in order to retard their time of blooming. Plums do well on the spur system generally, and should have all natural spurs retained. Cherries bear their fruit in exactly the same way, but with Morellos the wood oftentimes becomes so thick as to exclude light unless judiciously thinned out from the centre of the bushes. Black Currants produce their fruit generally from the young wood of the past season. Young growths, therefore, should by all means be encouraged, merely removing some of the old shoots to open the centre of the bushes, and shortening the points of straggling shoots, which is all the pruning the bushes require. Red and White Currants bear their fruit principally on spurs, it is therefore advisable to prune these much closer than the Black varieties. Gooseberries carry their fruit in a similar manner, producing it on both the spurs and on the past summer's growth; therefore retain a sufficient number of young shoots at moderate and regular distances apart, keeping the centre of the bushes open that the sun and air may act on as large a surface of foliage as possible.

Apples and Pears as espaliers produce their fruit on spurs. The branches should be trained horizontally along the side of walks, &c., and should have all foreright shoots and large, rugged, projecting spurs cut away, being careful to preserve a sufficient number of healthy fruit spurs for next season's supply. Standard, bush, and pyramid Apples and Pears require very little pruning except to regulate any unevenness in growth that may arise, for a too free use of the pruning knife doubtless causes more leaf-growth than fruiting wood. In all cases of pruning cut to an outer eye in order that the new growth may be naturally placed on the outside, and thereby make a more open growth that the light can penetrate among the branches more freely.

DRAINS.—It often happens that where common drain pipes are laid across lawns or in garden paths, that in the course of a few years they become choked, and the drainage of the ground is impaired thereby. The roots of Elms and such-like trees occasionally gain access to the pipes, and in a very short time completely stop the drainage. Whenever any indication of this kind exists there is no other remedy but to take the drain up the whole length that it has become choked, clear the roots or soil out, and relay the pipes. We have in extreme cases, where trees plentifully abound, put a mixture of tar and gravel over the pipes, which has had the desired effect of keeping the roots out. The present will be found an admirable time for any alterations of this kind; and unless in the case of very shallow drains, the work can

be done during severe frosts. Drains should always run along the centre or sides of garden paths with plenty of gratings to quickly carry off the surface water that rapidly collects during heavy showers of rain. In flat level places the gratings will not be required so plentifully as in hilly or uneven surfaces. These "eyes" or gratings are placed over small wells formed generally of bricks, and about 1 foot or 18 inches deeper than the outlet of the drain into which they enter. It is important that these catch-pits be cleared out regularly; if this is neglected the sand and gravel accumulate and choke up the pipes. In laying drains it is always well to make the bottom for the pipes to rest hard and firm, otherwise in course of time the soil underneath may sink, and an irregularity be formed in the drain. This will be particularly the case in newly made grounds, and cannot be too carefully provided against. A slight and continuous fall should be allowed for the free transit of the water. For garden paths 3 or 4-inch-bore common unglazed pipes are sufficient, but for more particular purposes the glazed socket pipes will be found much superior. All drains should have a quantity of open material placed next to the pipes, such as clinkers, brick rubbish, or burnt clay if obtainable; and in heavy soils, if none of these are to be had, we are careful to place the top spit with the turf downwards next to the pipes. The surface of the drains must be beaten down firmly, especially across lawns, or it will sink, and the turf have to be raised again. A very good plan is to leave the surface slightly raised to allow for sinking, merely placing the turves temporarily on the top for a time until all fear of sinking is over.

WORK FOR THE WEEK.

KITCHEN GARDEN.

DURING the presence of snow and frost combined the ordinary routine of this department is interrupted, yet there is much useful work which may under such circumstances be performed. Pea sticks may be cut and prepared, stakes made in sizes for various purposes, along with pegs for layering and twigs for securing the summer growths of wall trees such as Peaches, Nectarines, and Morello Cherries. The young shoots or clippings of Privet hedges are most suitable, stripping off the leaves, tying the shoots in bundles at both ends to straighten, and placing them in a shed where they will become hardened. Roots in store-houses should have the needful attention both in sorting them and making them secure. Emptying pits of decomposing material and the turning and mixing of compost heaps will be suitable employment in severe weather. The filling of the ice-house demands attention at the earliest opportunity. In the old-fashioned egg-shaped wells sunk in the ground on the side of a hill, or with a mound of earth raised over them and trees planted so as to afford shade, ice keeps remarkably well if efficient drainage be provided and the drain is properly trapped, a floor of spars or battens being at the bottom for the ice to rest upon, thereby allowing the water from the melting ice to pass away freely. Faggots are sometimes used for the floor of the ice-house, but a floor formed of battens is better. It is necessary that the ice be broken small and be made very firm. A little clean dry straw may be placed against the sides of the house, some thinking the ice keeps better, but we do not employ any straw at the time of filling, finding the ice keeps better without it. In the case of damp walls there is an advantage in a thin lining of straw. It is desirable to have the house opened during the prevalence of frost before the ice is put in, the draught through drying it and lowering the temperature of the surrounding surfaces.

Forcing Department.—Advance successional crops of Asparagus, Seakale, and Rhubarb according to the demand, making preparation of fermenting material for succeeding supplies. Water abundantly when required the beds of Rhubarb and Seakale in Mushroom houses, and afford ventilation liberally to Asparagus in bearing whenever the weather is favourable. Lose no opportunity of ventilating Lettuces in pits where heat is applied, also Endive in such structures, it being more safely wintered and blanched in pits where means are provided for excluding frost. Make up beds of leaves and stable litter mixed in pits or frames for Potatoes, also for Carrots and Radishes, seed of which may be sown in alternate drills 4 inches apart, employing fine rich soil. When the plants appear plenty of air must be admitted. French Breakfast and Wood's Frame Radishes, with French Forcing Carrot, are the most suitable varieties for forcing. Sufficient sets of Potatoes should be provided for planting by inserting them in leaf soil in boxes in a temperature of 55° to 60°, from which they may be transferred to the beds prepared for them, planting the sets in rows 15 inches apart and 9 to 12 inches asunder in the rows. From 6 to 8 inches of turfy loam and leaf soil in equal parts should be placed upon the beds, planting the tubers about 4 inches deep. Lettuces and Cauliflowers in cold frames or under handglasses will not suffer if the coverings or snow remain on for several days provided the external air be at or below freezing, and if the plants become frozen they should not be exposed until a thaw sets in. Cauliflowers and autumn Broccoli laid in pits with heads in a fit or advanced state for cutting must have sufficient protection against frost. Sow French Beans at intervals

according to the space and requirements. If large requirements have to be met, a low span-roofed house with a border on each side efficiently drained and having a depth of 10 inches of rich light soil will give fine rows, yielding abundantly provided proper attention is paid to watering, and occasionally mixing with the water a little guano. The beds ought not to be more distant from the glass than 2 feet 6 inches, and the house a light one with means of affording a temperature of 60° to 65° by day in dull weather and at night, except in severe weather, when a decline of 5° may be allowed; 70° to 75° by day with sun heat and moderate ventilation. A few roots of Tarragon and Mint should be introduced to a vinery or other house where forcing is being carried on. Mustard and Cress sow at intervals according to the demand. Introduce Chicory to the Mushroom house for blanching, or any dark place will answer where there is gentle heat.

FRUIT HOUSES.

Cherry House.—The house for affording ripe fruit from the middle of April should now be closed. Employ no fire heat unless it be necessary to prevent the temperature falling below 35°, not exceeding 40° at night by artificial means, and 50° in the daytime, being very sparing of fire heat at the commencement of forcing. From 55° with sun heat ventilate freely, avoiding at all times a confined atmosphere. The trees and all available surfaces of the house should be sprinkled or syringed early in the afternoon of fine days, along with a gentle damping in the morning, but in dull weather only damp the trees, &c., occasionally or when they become dry. The border must have water to bring it into a thoroughly moist state, and trees in pots if at all dry will require repeated supplies of water to secure the thorough moistening of the soil to the base of the pots. Plums being amenable to the same treatment as Cherries, the same remarks apply to both.

Figs.—Early Figs are best secured from trees in pots, as a slight warmth at the roots is highly beneficial; but even this has its disadvantages, as when the heat at the roots is 70° or more during the early part of the forcing process the growth is too rapid, therefore see that the heat at the base of the pots is not more than that until the leaves are unfolding, when the temperature may be 75° or even 80° at the base of the pots. The temperature of the house should be increased gradually to 60° at night, 65° by day by artificial means in severe weather, 5° more in mild weather, 70° to 75° with sun heat and moderate ventilation, closing at 75°; but be very careful not to bring on the growth too rapidly, especially in dull weather, as foliage produced under such conditions is not of stout texture, but thin and liable to scorch under bright sun, and to invite red spider. Water in a tepid state must be applied to the roots as required, and the trees and house must be syringed morning and afternoon so as to have the foliage dry before night-fall, damping the house later in the day if the atmosphere has become dry. Houses which are to be started early in next year should have the frost merely excluded now, completing the needful operations in cleaning, pruning, dressing, and tying the trees in later houses.

Vines.—The inside border of the earliest house having had a good soaking with water at a temperature of 90° when the house was closed, and a bed or heap of fermenting materials placed within the structure, the buds will be swelling fast, but do not be in too great a hurry in increasing the temperature by artificial means; the fermenting materials being turned over, a part each day, and a little fresh sweetened material being added, a certain amount of steam will be given off highly favourable to the Vines breaking evenly and strongly, the young shoots luxuriating in a soft genial atmosphere. Remove the foliage from late Grapes as fast as possible, cutting off all laterals below as well as above the fruit. This will apply more particularly to young Vines and such as have not ripened the fruit until very late. Any Vines upon which the foliage is off should be pruned as the Grapes are cut, which will more effectually secure rest. Heavily taxed Vines cannot rest too long. Any outside borders not yet top-dressed should have a covering of manure at once, and in fine weather point over or loosen the surface, and afford a dressing of turfy loam with the grass reduced with a twentieth of half-inch bones intermixed, and again cover with litter or some other protective material. Not infrequently the surface of the border forms into a crust of hard inert soil. This should be removed down to the roots and replaced with fresh compost, which will be advantageous, encouraging them nearer the surface. A covering of leaves with litter over them to keep them from being displaced by winds should be placed over the border, but not so deep as to heat, which is more injurious than otherwise for Vines not required to be started for some time as yet.

Peaches and Nectarines.—Except for very early work the forcing of trees in pots is not advisable, as they do not afford such fine fruit as trees planted out and trained to trellises where they can have plenty of light, but a few trees in pots afford very acceptable early fruit, and that to the advantage of the planted-out trees which need not be started so early. If the pot trees have a light airy house or pit with the convenience for making up a bed of leaves with about a third of stable dung and well sweetened, the pots being plunged in the bed, taking care that the heat at the base of the pots does not exceed 65°, they will root in the material,

the heat inducing free root-action and securing free swelling of the buds and young fruit. Though there is an advantage in the gentle warmth at the roots, it is not, however, indispensable. Failure with trees for early work arises chiefly from the trees in pots not having been prepared for the purpose—i.e., grown-on in heat the year previous so as to acquire an early habit for forcing early in the year. Trees for that purpose should be potted in early autumn and grown in heat from February. When the trees in the earliest house are in blossom damping should be resorted to only on bright days in the morning and early in the afternoon, avoiding a close moist atmosphere, ventilating freely whenever external influences admit, leaving a little air on constantly, maintaining a temperature of 55° by day, increasing the ventilation gradually to 65° with full air, closing at 55°; 45° to 50° being a suitable night temperature, but 5° less in severe weather is better than firing too hard.

PLANT HOUSES.

Greenhouse.—For affording a display of bloom no plants surpass the different varieties of *Azalea indica*, they being so accommodating in flowering at an early or late season; and the ease with which the plants are cultivated, provided they are kept free of insect pests, renders them all the more valuable. They suffer, however, in their resting season from being kept too dry, while they start into growth instead of flowering if kept too warm and moist. They should never lack proper supplies of water at the roots, and if they are kept at from 40° to 45° by artificial means they will be freer from insects, and not being unduly started into growth will flower more satisfactorily. Thrips are their great enemy, and though the low temperature to which they are subjected lessens the pests their eggs remain, only waiting an increase of temperature to be brought into life. Fumigation destroys the insects but not the eggs; besides, unless the plants have been grown in a light house the foliage is so tender as to be seriously damaged by fumigation strong enough to kill the insects. Dipping small or syringing large plants with tobacco water destroys both insects and eggs. One pound of tobacco cord should be boiled in a gallon of water for a hour, with 1 oz. of soda and 2 ozs. of soft soap, the latter being added while the liquid is hot; strain, and when cool it is ready for use. Any plants too large for dipping may be laid on their sides over a vessel large enough to receive the liquid as it is syringed on the plants, taking care that the dressing reaches every leaf. The plants whether dipped or syringed must remain on their sides until dry, so as to keep the liquid from running down to the roots. This cleansing should be done before the young wood buds begin to push, and in the case of badly infested plants repeated in a fortnight. Plants for forcing should be well dressed before being placed in heat. Many other plants may be freed of thrips by the same means, but the solution must not be used upon plants with young tender growth. Camellias that have not begun to swell their buds for flowering should have the leaves sponged to free them of dust or other accumulations. If there is any scale remove it with a rather hard brush—a tooth-brush answering perfectly. If any plants are not so forward for flowering as is desirable a slight increase of warmth may be afforded, but it ought not to exceed 50° by artificial means, and even at that temperature if the air be dry the buds may be cast, whilst if the buds are backward and moisture accompanies the heat the plants break away into fresh growth. Weakly plants swelling their buds may be assisted with weak liquid manure, not allowing any plants to become dry at the roots, which are always more or less active, and at no time is water more required than when the buds are swelling.

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense. Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

STRAWBERRIES IN POTS (A.B.).—The plants placed in the greenhouse at the end of the year not thriving, whilst those placed in the house at a later period do well, shows the crowns to be indifferently developed, owing probably to the plants not being potted as early in the season as possible so as to make and mature good growth; hence they have not sufficient time to rest, the trusses consequently coming up weakly, and the flowers going blind from being excited into growth too soon and too quickly.

ANGELICA (J.P.).—Being a native of this country it is perfectly hardy though made somewhat tender by cultivation. It grows well in any good garden soil, but succeeds best in moist cool situations. Being a biennial the seed should be sown when ripe or in August, covering it lightly with fine soil, watering frequently until the plants are up, and afterwards in dry weather. The plants may be thinned to 2 feet distance apart every way or be transplanted that distance in the following March, keeping them clear of weeds and watering abundantly in dry weather. In the following May or

June the stalks will be fit to cut, which must be repeated every year at that time so as to keep the plants from flowering; they will then continue for some years, but if allowed to seed they perish soon afterwards.

ECHEVERIA RETUSA AND GLAUCA (H. P. S.).—Though allied to the House-leek they are distinct from that plant, and, unlike it, are not hardy, requiring to be kept in a house from which frost is excluded, in a position free from drip, and with no more water than to maintain the leaves plump, it being better to err on the side of dryness than overwatering. *Spiraea* and *Hoteia japonica* are identical.

EVERGREEN OAK (G. R. A.).—The sprays sent appear to be those of the Anstrian Oak, *Quercus austriaca*, which retains its foliage throughout the winter. The foliage is glossy, deeply cut, and handsome.

CRYPTOMERIA ELEGANS (J. E. L.).—It is quite usual for this elegant Conifer to change its colour and become bronzy in winter. Your young plants will no doubt pass through the winter safely without protection and will resume their green garb in the spring.

FLUE-HEATING (D. B., Brizton).—We have seen flues formed of large drain pipes which have answered very well, but as a precaution against the pipes cracking we advise you to have the flue of bricks for the first 6 feet from the fire. Hot-water is preferable to flue-heating.

FORCING POTATOES AND RADISHES (A Beginner).—We presume you have some kind of fermenting matter to afford a gentle warmth, and we should place it in the pit at front to the depth of a foot, and at back 24 inches deep, which will leave you a foot to the glass. Leaves will answer, and with 6 inches of soil upon them will be so firm as to leave you a foot clear in a short time. The soil should be rich loam, light rather than heavy, and when it is a little warmed you may plant the Potatoes in rows 18 inches apart, and the sets a foot apart in the rows, placing them 4 inches deep. Radishes may be sown over the surface, and the seed be either raked in or covered with half an inch of soil. All the treatment required is to expose fully when the weather is mild, and protect from frost by mats and straw coverings in frosty weather, not removing them in continued severe weather until a general thaw. If you can command an abundance of protecting material commence at once, but if not we should defer planting until early in February, in the meantime having the sets in a suitable place to sprout. When they have pushed shoots from one-half to three-quarters of an inch long you may plant. We grow in frames Sandringham Ashleaf, Myatt's Prolific Ashleaf, and Veitch's Ashleaf. The first is earliest, but the last two are better croppers, and for your purpose would be most suitable.

MARANTA UNHEALTHY (A Subscriber).—These plants become unhealthy from various causes—by excessive moisture at the roots on the one hand or drought on the other, by low temperature, a too dry atmosphere, and by bright sun. Do not disturb your plant at present, but place it in the warmest position of your house, keeping the soil just moist. In the spring, when you can command 20° more heat, carefully shake the plant out of the old soil and pot it in a rough open compost of turfy peat and charcoal, and place it in a shaded part of the house, maintaining a moist genial atmosphere to promote the growth of fresh foliage. A minimum temperature of 50° is fully too cold for your plant.

HEATING A GREENHOUSE (L. M.).—The stove is evidently not large enough for heating your house. If you object to a flue or hot water your only course is to obtain another stove. You will not now be able to procure one from the same maker, but you will have no difficulty in finding one that will aid in excluding frost. You ask for instructions to enable you to obtain "sufficient heat," but neither state what amount of heat you require nor what kinds of plants you have in the house.

MANURING FOR POTATOES (Bricks and Mortar).—As the land is required for building purposes and you only want one crop from it we should not, unless it is very poor, apply any manure until the Potatoes are planted. We should then sprinkle a little superphosphate of lime in the drills, just making the ground white, and if further support is needed we should top-dress during showery weather when the Potatoes had grown a few inches high with the same fertiliser and a sprinkling of guano.

PETROLEUM AS AN INSECTICIDE (A Subscriber).—In syringing the plants they should be laid on their sides or be held over a tub containing the solution; very little petroleum will then drain into the soil, and that little will not do any injury. It is not easy to name a Fern from such small scraps and those imperfect, but we think it is *Pteris argyrea*.

PRUNING MARECHAL NIEL ROSE (Agricola).—The shoots nearly 10 feet long should only have the tips removed if you require a large supply of blooms next year. The growth of the weakly plants should be pruned rather closely in order to produce still stronger shoots next year for flowering in 1880. Roses in the open air should not be pruned until spring, and in due time instructions will be given in "Work for the Week" on the subject.

LOASAS (Somerset).—The following is the description of the flowers:—Calyx tubular, with four or five lobes, adhering to or closely girding the ovary. Corolla with four or five concave petals, inserted in the throat of the calyx, or double that number and disposed in two series, the interior being the shortest, and sometimes in the form of scales. Stamens indefinite in number, distinct, or united at the base in several bundles. Ovary inferior, one-celled, with three, four, or five partitions, issuing from its inner surface. Style simple. Stigma either entire or four-lobed. Your other question will be answered next week.

MANURE COMPANY (Seventeen-years Subscriber).—We have no knowledge of the Company you refer to.

NAMES OF PLANTS (G. H.).—The berried plant is *Eugenia Ugni*, and the other *Habrothamnus elegans*.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

THE MANAGEMENT OF SWINE.

THE first thing to be considered relating to this subject is the pens or sties for the accommodation of the animals. These are commonly treated as the least important of all the buildings on the home farm, and great improvement can not only be made

for the well-doing of the pigs, but also for the preservation and retention of the manure. It is requisite that the breeding sows, the boar, and the store pigs, as well as fattening pigs, should have separate apartments, and as each will require a different design for their accommodation we shall allude to them in detail. Having often superintended the erection of sties upon home farms we give the dimensions, &c., which we recommend as best adapted for the comfort of the animals, facility for feeding, and for the saving of manure in the most available condition. It often happens that on some farms there are existing sties which it may be economical to retain and make use of by such alterations as will make them useful under an improved system, and therefore by stating what we consider the best accommodation as a new erection it will serve to point out what changes may be made in sties now in use should they require alterations or additions.

The best aspect for the frontage of the pig pens is to the south or west; in fact it is the best plan to have two ranges with a meal house with boiling coppers and cisterns for grains, wash, and mixed food in the centre, with easy access at the back of the building for the carting and delivery of materials required, such as roots, meal, &c. We propose to consider our subject under two separate headings—first, the best management adapted for breeding sows and their offspring; and secondly, the rearing of store pigs from the time of weaning and the fattening for sale at different ages. The range of buildings to afford the best accommodation for breeding sows should have a south frontage. The span of the buildings should be 20 feet, roofed with slate, the eaves being 7½ feet from the ground level. The arrangement for each farrowing sty should include the whole 20 feet under cover, and 10 feet in width, and it should be divided; the interior or nesting place for the sow to be 7 feet by 10 feet. The floor should be raised 12 inches above the ground level, and be formed of flagstone or concrete with cement. We object to brick, as being always more or less damp. Sometimes boards are used, but they in ordinary use are also damper than stone or concrete. The floor should be laid with a fall of 1 inch to the foot towards the outer division of the sty; a rail should also be attached to each side of the pen about 10 inches from the floor, and projecting about 10 or 12 inches. This is called a sawall, because it provides an escape for the little pigs when the sow lies down, as they can run under the rail behind her back instead of being overlaid. This nesting place or interior division should not be littered with long straw, but only with chaff cut into lengths of 4 or 5 inches, and kept entirely free from dung; then at the time of farrowing there will be no accumulation of straw, which is often the cause of loss of young pigs not being able to keep out of the way of the mother when about to lie down. There being a wicket 2 feet wide to the inner pen or division the sow may when near farrowing be confined to this apartment, only being let out to feed in the front division. This division should be 13 feet by 10 feet, the floor being sunk 1½ foot below the ground level for the purpose of holding the manure, with 6 inches of dry earth or ashes at the bottom for absorbing the urine. The shorter the straw for bedding the better, which should occasionally have a sprinkling of earth or ashes to consolidate the mass, which may then be allowed to accumulate as long as convenient. In this outer apartment the iron trough will be placed, and any green food may be strewn over, this being the feeding apartment. The trough not being a fixture will rise with the accumulation of the manure. The feeding will take place through a wicket 3 feet wide from a pathway outside, raised 12 inches above the ground level and 2½ feet wide, which may be pitched with stone or brick and kept clean at all times, and will give access to each of the sties alike. This raised path also gives protection to the pens, because it answers the purpose of a stopping block when the carts are engaged bringing food, litter, or earth, and removing dung, and prevents damage to the building by carts being backed against it. The front of the pens may be of wood or sheet iron galvanised, and about 4 feet in height above the level of feeding path, which may or may not be covered by a projecting roof as may be required. This feeding path is placed in front,

because we object to the usual feeding path inside, it being unreasonable to expect that the sow can farrow in comfort and quietude when the feeding trough is a fixture in the apartment or lair, and some sows when disturbed at such a time will destroy their little ones in consequence, nor do we approve of any interference whatever with the little pigs or the mother at farrowing time, hence the care we always take to keep the inner apartment completely private.

The feeding of the sow must now be considered. It is best to give cooked food for a few days or a week, first with bran or sharps with skim milk, afterwards with boiled cabbage, carrots, Swedes, or small potatoes mixed with bean or barley meal, and a little milk added when it can be obtained. With this food the supply of milk will be good. The little pigs will require to be fed separately when about fifteen or twenty days old in this way: Feed the sow first, and then shut her into the inner apartment whilst the little pigs receive their food in the front division, which food should consist of skim or butter milk and bean or barley meal; to this may be added as they increase in growth boiled roots of some kind as before named. At about six weeks old they may be castrated and spayed, except those required for breeding purposes, and in reserving sow pigs take care to save only those which have at least twelve teats. As the pigs should be weaned and taken from the sow at about ten or eleven weeks old they should be fed up to that time with a liberal allowance of cooked food. Any kind of roots with meal will answer the purpose except mangolds; and in case they are to be kept on for store stock only, after being weaned they should have beans or peas to eat twice a day; this will enable them after being weaned to live upon the coarser food—such as roots with maize, beans, or peas—to keep them in a growing state.

We must now refer to the young sow pigs intended for breeding. These may be fed with the store pigs as just stated, for we do not approve of high feeding for breeding sows, nor do we approve of their being put to the boar until they are eleven or twelve months old. They will then at farrowing time be able to sustain and rear up a full number of pigs at the first birth. This is really a matter of much more importance than is generally supposed, because when sows are bred from at too early an age they are more likely to bring a short number of pigs at the first birth; and it must be remembered that so many teats as suckle pigs at the first birth, just that number will furnish a full supply of milk at future births. For instance, if a sow rears up seven pigs only at first birth, and she brings ten pigs in the next troop, three out of the ten will be poor weakly animals, because they must be reared by those teats which were not in use by the first farrow of pigs. This circumstance has always induced us to defer breeding until the sows are of full age, besides which they become larger animals, and have greater resources both in body and constitution for sustaining their offspring. After the little pigs are weaned, which should be done by taking the sow from them instead of taking the pigs from the mother, we recommend that the sows should have plenty of liberty and exercise, for we have noticed that sows kept entirely in the pen will bring but few pigs at a litter; but when kept as we recommend—that is, to have the use of a small yard where dung is stored, and be fed there with roots, &c., all their dung will then be added to the manure heap, and if they have a small hovel to lie in they will do well. The fencing may be of iron hurdles.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—Wheat-sowing will be continued on all dry soils where roots are being fed off, particularly in those cases where the quantity already sown is not up to the average usually sown upon the farm. Managers of a home farm need not be deterred from sowing wheat after this time at every opportunity when the weather is open and the land can be worked, so as to drill the seed and insure its being covered in. We recollect on various occasions when we have sown wheat about this time, and when frosty weather has set in immediately and prevented the wheat germinating, that we have never known it take injury on that account, although it may have lain in the ground for six weeks. Wheat is very hardy, and when frost sets in when the seed grain is only just sprouted even then it does not injure but only delays its appearance above ground. Some farmers object to sow wheat in the month of January, and we have always found it to answer best to sow as soon after Christmas as the state of the land would admit, as the land settles down much firmer and the crops grow more like autumn-sown wheat than when sown in February or March. The crop is always more infested with weeds when sown in the latter month, and in consequence it should be drilled at 9 or 12 inches apart in order that the horse hoe may be freely used. We have been over much land in different districts during the past few weeks, and the complaint is very general that women and lads are not to be obtained as formerly to do the weeding upon the corn crops. This of itself is a strong reason why wide drilling for all sorts of corn should be adopted, particularly upon those soils infested with the deep-rooted thistles. Should frost

continue manure and chalk may be drawn on to the clover. This is advised, because on the home farm generally the farm-made manure should be drawn out whilst fresh and new, as it goes so much further than when allowed to remain in heap for a considerable time, for it is certain that it loses some of its value by heaping, besides the extra expense of a second carting. The odd horse will find constant employment in carting hay for the sheep and other kinds of cattle, also roots for the stock in the yards and boxes.

Hand Labour.—Corn may now be threshed and delivered; hay may also be sold, trussed, and delivered, as labour is of less importance at this time of year, and if these matters are delayed until the spring of the year they are sure to displace work of more value. There is sure to be a considerable quantity of straw required as fodder for the young cattle, for the furnishing of which threshing must be continued. It is only in a few districts that the flail is found in use; but still it is in use, and some prefer barley threshed with the flail, the corn being less damaged for malting purposes. It is, however, quite impossible to recommend it in preference to the threshing machine for many reasons which will occur to the mind of every experienced home farmer. Chalk may now be brought to the home farm in all the loamy land districts, and placed in a dry situation, such as a barn mow; and as soon as it is sufficiently dry it should be screened and got ready to drill with the turnip crops of next year instead of ashes, it being found to prevent the clubbed roots in both Swedes and turnips, also cabbages. The young cattle now coming two years old if they have been liberally fed from birth will soon be fit for sale. They will usually make about 20s. per month from the date of birth. At this rate, if they have been fed under cover winter and summer with judgment and economy, by having no more food than they can assimilate, they must be considered to have paid for feeding. In the southern and home counties the lambs from the horned Dorset ewes will soon be fit for sale, and it is reported that the early Dorset downs have commenced lambing with good results. The weather is now such that a lambing fold must be got ready, and if possible near to the cottage of the shepherd; if not those shepherds' houses on wheels, particularly those with a stove fitted inside, should be used, because in hard weather when the lambs fall fast many of them, especially in the case of twins, will often be lost if they cannot be placed near a fire or warmth of some kind, and to assist the young lambs cow's milk also ought to be available for use when the ewes happen to be short of milk.

VALUE OF WOOD ASHES AS MANURE.

THE experiments carried on with leached wood ashes in America continue to be favourably reported on, and to win more friends every year. They have been used for many years by the farmers and market gardeners of Long Island, and later by the same classes in the seacoast towns of Connecticut, and also on the tobacco farms farther inland. Leached ashes contain considerable quantities of potash and phosphoric acid, which have a wonderfully invigorating influence upon exhausted soils. The onion growers make large use of ashes, buying them sometimes by the thousand bushels. Fruit-growers are much pleased with its effect upon the growth of trees and shrubs, and upon their productiveness. Their effect is said to be immediately visible in old pastures and meadows, sown broadcast as a top-dressing; but they act still more satisfactorily if applied to the crops at the time of seeding down. They not only largely increase the crop with which the grass seed is sown, but their influence is visible for many years afterwards in the increased yield of grass. A farmer who has used ashes freely for twenty years upon a hard, worn-out gravel soil says they will give an increase of hay upon a meadow newly stocked for eight years; and then, if the field be ploughed again, they will show the effect of the ashes for six years longer. He applies about one hundred bushels to the acre on land that he designs to keep in permanent meadow, and about seventy-five bushels to pasture land. It is particularly satisfactory as an application to a rye crop, even in so small quantities as twenty bushels to the acre. He has reclaimed a large breadth of old fields given up to the growth of bushes, briars, and brakes, and made it a fine pasture by taking rye crop manured with ashes. He considers leached ashes his most efficient helper in transforming an exhausted worn-out farm into one of great productiveness, giving a fair reward for his capital and labour. In commenting on the value of wood ashes, Professor S. W. Johnson, of New Haven, Connecticut, says, in the *Country Gentleman*, that wood ashes are a good fertiliser is well proved; that they often do well on all kinds of crops and a great variety of soils is a perfectly authenticated fact; that they often show no perceptible influence on this or that crop, on this and that soil, is another fact no less thoroughly established; that in a multitude of cases wood ashes would give good crops, but some other fertiliser would give better ones at less cost, may fairly be inferred from the recorded experience of careful experimenters. In the face of these uncertainties local experience of the nature of the soil crops, &c., is the best guide in their application; and if

there is none to appeal to, a trial on a limited scale should be made to test its powers.—(*Journal of Forestry.*)

THE LATE DISQUALIFICATIONS.

We have long been accustomed to hear laments over the fact that poultry and Pigeons are often exhibited, not as Nature made them, but much improved by art, and that such birds not unfrequently gain prizes. Doubtless there has been some exaggeration as to the extent to which such practices have been carried; but leaving a wide margin for this, it is notorious that judges have winked at many dishonourable trimmings of feathers and cutting combs. The harm that has thereby been done is not easily calculable; we could name many genuine fanciers—i.e., real lovers of beautiful and highly-bred birds, who have in consequence, not indeed ceased to breed such, but have entirely declined ever to exhibit them. We began ourselves with Spanish, and for two or three years bought high-class stock and bred carefully, but never got even a modest commendation, for the reason that we had no conception that anything by way of improvement was ever done to their faces. We sold our stock cheap, and in the hands of experts they carried all before them at the greatest shows. We mention this fact solely as proof how easily young fanciers may in disgust be driven out of a charming pursuit. We tried another breed ourselves, and were fortunate enough to hit upon one which is less capable than any other of any artistic improvements, and were successful at once, but for one disappointed exhibitor who is thus persevering probably there are three who give up in disgust.

We have become almost tired of reading and hearing the not unnatural complaints of the scrupulous who have suffered from the unscrupulous, because so little seemed to result from these complaints. So long as judges continued to give prizes to trimmed birds, trimmed birds were sure to be shown; and as long as judges felt that they were not seriously and systematically supported in showing up all cases of trimming, they were not likely to be over-curious in trying to find them out. Now, however, things seem to have changed, the vague clamour against trimming has developed into definite determination to support the judges in putting it down. They understand this, and have, we are glad to see, begun to act upon it. At the late Crystal Palace Show more than one pen was disqualified, and these disqualifications were very generally hailed with satisfaction. We do not for a moment mean that there was any satisfaction evinced at the particular instances, but at the evidence of determination on the judges' part no longer to wink at malpractices. It is quite possible that some of the first victims of this improved state of things may, in a way, be hardly dealt with. Much tacit encouragement has doubtless been given to trimming, and specious reasons have been found for showing birds "to the best advantage," as we lately heard it termed, but the benefit to fanciers in general will, we are certain, be very great. The same course has, we hear, been pursued elsewhere by the same judges, and very thoroughly by another judge at Norwich. So far so good, but we cannot help wishing that some manifesto might be drawn up and published, either by a board of the most experienced judges, or through the Poultry Club, to which several of the most eminent judges belong, stating plainly what is and what is not to be considered trimming in each breed. A fair warning would thus be given to those who have been led on by custom to do what they do not approve of, and young fanciers who may buy stock from expert breeders will so gather hints as to where to look out for points in which they may be taken in. Of course such obviously improper trimmings as the plucking of hocks and tails would need no enumeration, but it would be well that all doubt should be cleared up as to such points as to the skinning of Game cocks' throats (dubbing we put out of the question as defensible on totally different grounds to all other trimming), the shaving of Spanish faces, the pulling of feathers from the front of Polish crests, and the carving of Hamburg combs. The latter has always seemed to us the most objectionable of all these practices, for by it a bird with a gross hereditary fault may be made to appear almost perfect; and this is the very case in which, in our opinion, judges have been hitherto too lax. The object of those who have most strongly advocated judicial severity is not, we are sure, that this or that person may be detected in malpractices and made an example of (though this may incidentally be desirable as a deterrent), but that the fancying public may be made to understand that a new start must be made on stricter principles, and abuses which have by degrees come in must be put down with a strong hand. This will more easily be accomplished if it is clearly known and understood what are abuses, and for this reason we should much like to see some category of them drawn up by those who would speak with authority.

FWLS PROBABLY POISONED.

My fowls have failed quite suddenly. They mope with tails drooped, and do not care to eat. On looking in the hen houses I could see they were suffering from diarrhoea; I could detect blood in their evacuations. I found one dead on Saturday, and several since. On inspecting the dead birds I found their throats in-

flamed. I am treating them for inflammation of the mucous membrane. I gave them all to-day three parts of a teaspoonful of castor oil; to-morrow I shall give them a mixture of three grains of hydrargyrum cum creta, three grains of rhubarb, and three drops of laudanum in a teaspoonful of gruel. They have a good dry run, good holly hedge to scratch under, and a dry shed with plenty of grit, a large orchard to run in, and a field adjoining. In a dry corner of the orchard I have all the garden refuse put. They have plenty of grass, clean water, and everything requisite for them to do well; in fact they have done well till last week, hatched out ninety birds of eleven sittings, only had two die, one crop-bound and one found dead. As soon as I found them failing I mixed some barleymeal and toppings, added some cayenne pepper and rue chopped small. I have not given them any hard food since. My general way of feeding is maize and barley in the morning, a few oats and peas in the afternoon, barleymeal and toppings with a little cayenne pepper or kitchen stuff. I am always changing food some way or other, and have the best I can buy. I always give soft food once a day at moulting time.—JOHN STRONG.

[We have little doubt from the description you give your fowls have had access to or have discovered something of a poisonous nature—an irritant poison. We advise you to keep on the castor-oil treatment, giving a tablespoonful for a dose. It may be given daily till the symptoms become favourable, when the treatment may be altered by a diminution of the doses, and a greater interval between them. Discontinue all other medicine unless you give Baily's pills which are very useful in these cases. The best change you can make in their food is to give ground oats (barleymeal if you cannot get oats), and it will be a very good thing if they are mixed with milk. Let this be the morning meal; at midday some maize or household scraps, and ground oats mixed as before in the evening. Give no pepper; you may give rue if you like, but it is not necessary. We do not approve of toppings. We have long cried out against the notion that the food which cost least was the cheapest. Money will only buy money's worth, and during a long life we have never been able to accomplish successfully for £1 that which cost other people £2. The least money has the least result. We like neither cayenne pepper nor peas as poultry food. We have always advised that in feeding poultry the habits of a bird in a state of nature should be the system to be followed. They seek no trifling changes in their food. They feed regularly and moderately; above all, early in the morning. It is not improbable the ailment may proceed from the weather. Fowls, like human beings, are affected by sudden changes. Simple remedies are the best. When fowls are suffering as yours doubtless are, the best remedy to rally them when weakened by the medicine is to feed morning and evening, especially the latter, on bread steeped in strong ale. We believe it to be always good in severe weather.]

GUILDFORD POULTRY SHOW.

THIS Show, in connection with the Show of the Agricultural Society, was held on the 9th and 10th inst. in the Green Market, Guildford—a miserable building for the purpose, open towards the street, and piteously cold and draughty. It was reported at the Show that for a very small sum the Skating Rink could have been secured for the Exhibition, which would have been a far better place. We trust that another year the Committee will be more provident, and not risk the exposure of the birds to such fearful cold.

The *Dorkings*, as usual, were good. The cup went to a grand pair of adult Silver-Greys. In the chicken class we much admired Mr. Taylor's Dark pen, third prize. The pullet was, we think, one of the Crystal Palace prize birds, and the cockerel large and round-breasted. We should have transposed them with the first pair, also Darks, the cockerel of which had very poor toes. The second chickens were good Silver-Greys. The winning pens of Whites were capital cup birds at some of the greatest shows. *Cuckoos* were also good both in size, colour, and combs; far better than any we saw at Birmingham. In *Cochins* a grand pair of Whites took first and cup for the best pen of large fowls other than *Dorkings*. They were birds which might grace any show. Second were also good Whites; third fair Buffs. Dark *Brahmas* were a poor lot. The second and third prizes were withheld. We thought the exhibitors hardly dealt with in this case, for the first-prize pen contained a regularly deformed and crippled cock. Light *Brahmas* were one of the best classes, the first winners being a handsome pen. *Spanish* and *Game* were decidedly poor. In *French* a pair of Crêves were first and *Houdans* second, quite as good of their kind. In *Hamburgs* two good pens of Golden-pencilled won, and some fair Blacks were also shown. In the Variety class pretty Japanese *Silkie*s were first, and White *Minorcas* second. *Game Bantams*, as usual at this Show, were excellent. First were Brown Reds, a trifle large but very stylish; second Black Reds, the cockerel splendid in colour with a poor hen. In any other variety Japanese were first and Black Rose-combed second. *Aylesbury* and *Rouen Ducks* were shown together, and were more numerous than remarkable. Black East Indians and Carolinas won in the Variety

class. *Geese* were poor and *Turkeys* excellent. We always see at this Show much variety of colour in *Turkeys*, fine Blacks, Whites, and Buffs being in the prize list.

There was one class for *Pigeons* of all sorts with seven prizes. We think this a mistake, especially now that the Surrey Columbarian Society hold their Show at this time. Twenty-one pairs appeared. The first (Yellow Turbets) and second (White Fans) were well-known winners; third were White Fans; fourth Homing Antwerps; fifth Archangels. We subjoin the prize list.

POULTRY.—DORKINGS.—Coloured and Silver.—Cup, 1, and 3, O. E. Cresswell. 2, J. Ivory & Son. *Chickens*.—1, J. Ivory & Son. 2, O. E. Cresswell. 3, J. Taylor. *White*.—1 and 2, O. E. Cresswell. *Blue*.—1, W. Virgo. 2, J. L. Playfoot. *COCHINS*.—Cup, 1, 2, and 3, J. Buckmaster. 3, A. C. Ede. **BRAHMAS.**—Dark.—1, H. Glover. 2 and 3, Withheld. *Light*.—1, W. Mitchell. 2 and 3, Rev. G. S. Davies. *vhc.* Countess of Lovelace. **SPANISH**.—1, Withheld. 2, A. Critchett. **GAME**.—1, J. Knight. 2, Withheld. 3, J. W. Taylor. **HOUDANS OR CREVE-CEURS**.—1, Rev. G. Chilton. 2, Rev. W. Pearce. **HAMBURGHS**.—1 and 2, O. E. Cresswell. **ANY OTHER VARIETY**.—1, O. E. Cresswell. 2, S. D. Timas. **BANTAMS.**—Game.—1, R. Osborn. 2, B. Randall. *vhc.* *Any other variety*.—1 and 2, O. E. Cresswell. **DUCKS.**—*Aylesbury or Rouen*.—1, J. W. Taylor. 2, J. H. Webber. 3, J. Ivory & Son. *Any other variety*.—1 A. & J. Wells. 2, J. W. Taylor. **GEES**.—1 and 3, J. W. Taylor. 2, T. Baker. *Gooslings*.—1 and 2, J. W. Taylor. 3, Withheld. **TURKEYS**.—1, Countess of Lovelace. 2, W. Alden. 3, E. Pilcher. **POULTS**.—1 and 2, F. Botting. 3, J. W. Taylor. *vhc.* Countess of Lovelace. **SELLING CLASS**.—1, A. & J. Wells. 2, A. C. Ede.

PIGEONS.—1, 2, and 5, O. E. Cresswell. 3 and 7, Burdett & Walker. 4 and 6, Rev. W. Pearce.

JUDGE.—Mr. W. J. Nichols, The Poplars, Merton Abbey, Surrey

CANTERBURY POULTRY SHOW.

THE annual Show of Poultry, Pigeons, and Rabbits was held in the Kent County Pavilion on Thursday last and following days. Small birds were this year omitted from the schedule, and provision was thus made for the large increase in the poultry and Pigeon entries.

Dorkings.—Coloured cock and hen—a capital class, nearly all the birds noticed. Cockerels also good, the competition between first and second being very close. Silver-Greys better in numbers, but not equal in quality to the Darks. *Cochins*.—Buffs, the winners in the cock and hen were a pair of stout birds, well feathered. A pen of Whites were first in the Any Variety class. *Brahmas*.—The Dark classes were unusually small, but of more than average quality, the cup going to a grand pen of old birds, closely pressed by a beautifully marked, large, well-feathered Dark pullet belonging to the same owner. Lights were larger classes, and contained a few good pens. *Spanish*, with the exception of the winners, poor. *Houdans*.—First a fine cock a little deficient in crest, matched with a grand hen large and even in crest. *Game* and *Hamburgs* were on the whole good. *Sultans* obtained only a poor entry. *Polands* were finely supported, and appear to be fast recovering their popularity. *Bantams*.—Game, first in Black Reds cock, very stylish, the Palace winner we think; second contained the best hen. In the class for Black and White Miss Ladd won with a pretty pen. *Ducks*.—Rouen, twenty-five entries, a splendid class, the Ducks in the winning pen being richly marked.

The *Pigeons* were much better supported than on any previous occasion, and a very marked improvement was visible in the quality. Carriers were a very superior lot; and here we noticed two or three of the best birds, that certainly should have found their way into the prize list, unnoticed by the Judge. The general impression was that he had passed them by accident; and of course exhibitors were not very complimentary with their remarks upon his awards, but we were afterwards informed that they had not escaped his attention, but that he found some so greased and others cut in the wattle that he could not give them a prize; and if the rule which prohibits tampering with birds means anything, for the reputation of the Judge a disqualified card should have been placed on the pens, and then the initiated would have learnt the cause of the omission in lieu of contending that it was through his want of appreciation. **Pouters.**—Cocks a surprising class of twenty-three entries, hens eleven. **Barbs and Tumblers** all good classes. **Dragoons, Blue and Silver**, poor. **Any other colour.**—Cock, a Chequer first, the Palace winner; second a moderate White; third a Grizzle of no great pretensions. A rich-coloured Red was also shown here, but an attempt to "Madame Rachel" it with the grease pot caused it to share the fate of the Carriers we have above described. Some Yellows in this class and in the hen class also, that have obtained the highest honours at the principal shows, were not here even decorated with a card. **Jacobins and Owls** were large classes. **Fantails** a charming lot, and obtained a special general commendation from the Judge. The Antwerps obtained a great entry, and some bargains were to be found in the large Pigeon Selling classes.

Messrs. Teebay and Nichols judged the poultry, Mr. Esquilant the Pigeons. A list of awards has not been received.

CANNED BUTTER.

SUCH has been the progress in the manufacture of American butter that that article is now marketed in all sorts of shapes, both for home use and foreign export. Fine creamery butter is made to retain its sweetness and purity, kept however long, in any

part of the world, especially in the warmer climates. Ships making long voyages, or parties going on a cruise and people living in isolated sections, with no opportunities for making or purchasing freshly-made butter, now no longer need eat poor butter, when a nice article can be obtained that will retain its flavour for an indefinite length of time. Canned butter now figures in the exports of the United States quite prominently. The butter is packed fresh from the churn, at the packing rooms of the creamery. In the method of regulating the temperature lies the great secret of the success which our American creameries have obtained. Butter sealed in cans is free from foreign substances, such as salt and pickle. It has no salt put in. When it is taken out of the cans to be used it is salted. A can of butter that had been sealed for nearly a year was found by an analyst to be as fresh as when made, and not affected in the least by the tin. Salt corrodes the tin and spoils the butter, and hence in canning it is not used, but only when the butter is eaten. It has also been ascertained by experiment that dairy butter is more liable to melt in a warm temperature than creamery butter, for the reason that the latter consists of only a single churning and is packed closer, while the former generally consists of several churnings, which are apt to vary in quality in hot weather.

The introduction of canned butter is destined to become a large industry, and the success of the movement is assured. The principal rival to American enterprise in this industry is Denmark, which country has for some years exported canned butter to various hot climates, but chiefly to South America. The great care taken by the Danish dairymen to preserve the grain of their butter has given them an advantage in the past, so far as the foreign export trade is concerned; but it is now claimed that the American-made article is superior to the Danish article in some respects, and that it can be and is sold at a less price than the Danish butter, which is its only competitor.

Very little canned butter is seen in our markets, and that little is put up by butter-makers for hotels and private parties who order it in that shape.—(*Western Stock Journal, Iowa, U.S.*)

BRITISH BIRDS IN DECEMBER.

DURING the past fortnight great changes have been going on among the wild birds of this country. Towards the middle and end of November the birdcatchers always expect what they designate the "November flight of Linnets." This great flight began this year about the 15th of November. On the 24th and 25th very large takes of Linnets were made by the London and suburban catchers. The men get their nets laid before daybreak. As soon as it is light the birds appear. They come in flocks of from two to three hundred; the call-birds "charge," and give the catchers notice that the birds are coming before they can be seen by the men. Very large takes of these migratory Linnets have been made; as many as five dozen have been taken at one pull of the clap net this year. Although so many Linnets are captured annually, there has been no general diminution noticed in their numbers. The principal part of these birds are bred on the wild gorse lands, especially in Scotland. They are very prolific, and have three or four nests each season, producing from fifteen to twenty young. When this Linnet migration from the north takes place, the birdcatchers are certain that some wild weather is coming behind them. This has been justified by the recent weather of cold and wintery rain. The Linnets when arriving at the south of England disperse themselves over the stubbles, "clover lays," and "fed-offs;" they eat large quantities of charlock and other wild seeds, which otherwise would be injurious to the farmer. The large takes of these birds have glutted the bird market. Before the flight cock Linnets were worth from 4s. to 5s. a dozen, now they are only fetching 1s. 6d. to 2s. A very rare bird has been taken among the Linnets at Highgate—namely, a hybrid between a common Greenfinch and Brown Linnet.

Goldfinches are now becoming very scarce, on account of the cultivation of land exterminating the thistles. This year, for the first time, the birdcatchers have gone expressly to Ireland, and have sent large takes of Goldfinches thence into the London market. During the autumn Goldfinches were abundant; the reason of this may be attributed to the provisions of the Bird Preservation Act. At this time of year the Goldfinches lie up in quiet feeding places, and remain there as long as the food lasts; they will not be seen on flight again until April. The Siskins, Chaffinches, Bramble Finches, and Hawfinches that came in the last Michaelmas flight, and located themselves where food was abundant, are now gone, and the birdcatchers cannot find their whereabouts. In all probability they will not show up again on flight until the middle or end of February.

Fieldfares, Redwings, and Missel Thrushes have arrived in large numbers, and are to be found about the environs of London so long as they can find food; they are very wary birds, but the moment frost and snow set in they are very easily approached. The Redwing of all the Thrushes is the most duck-hearted; he will soon succumb to the cold, even when the berry food is abundant; he cannot exist long without "ground food"—that is, worms and insects. Bullfinches are still plentiful, there being

abundance of food for them, such as old blackberries, privet berries, and dock seed; but they never begin on the privet berries as a rule until after the frost has touched them. The Aberdeens, or Siskins, have entirely disappeared, the cause being that there is no alder seed this year; the birds subsist almost entirely on alder seed during their stay here in the winter, and never breed in this country nearer than the north of Scotland.

The Scotch Larks are unusually abundant in England this season; they locate themselves on the clover and grass lands, where they are taken by thousands on dull nights with the trammel nets. At this time of year they are sold dead indiscriminately, both cocks and hens, just as they are caught. By the end of January the catchers can find ready purchasers of the live cock birds. The price of cock Larks then rises monthly up to the end of April. In January they fetch 4s. a dozen, in April there is a ready market at 12s. a dozen.

Woodpigeons are very numerous this winter, and large numbers are now in the London market. Just now they are in the very finest condition, and are regular "lumps of meat." They are very good for table when stuffed with sage and onions and roasted as are Ducks. When the severe weather sets in the damage that will be done to the farmers by Woodpigeons will be alarming; they will destroy large quantities of Swedes and turnips, spoiling more than they eat. These birds peck out the heart of the green part in the centre of the turnip; in doing this they make a deep hole, the water then gets in, and the turnips are destroyed by the first frost. This year there are no beech-nuts; the Woodpigeons, therefore, will more than ever make inroads among the turnips. Woodpigeons also do much damage to the vetches grown for early lamb feeding.—(*Daily News*.)

VARIETIES.

WE hear that in spite of some financial failure at the late Wolverhampton Shows, the public-spirited Committee have decided to hold another Show on January 24th, 25th, and 27th, under the rules of the Poultry Club.

THE report of the Council of the Royal Agricultural Society of England states that during the year 1878 the number of governors and members had been increased by the election of four governors and 451 members, and diminished by the death of five governors and 110 members, and the removal of 183 members by order of the Council and by resignation. The Society now consists of 79 life governors, 73 annual governors, 2377 life members, 4242 annual members, and 26 honorary members, making a total of 6797, and showing an increase of 157 members during the current year. The funded property of the Society remained the same as at the last general meeting—namely, £26,511 11s. 5d. New Three per Cents. The balance of the current account in the hands of the bankers on the 1st inst. was £942 19s. 10d., and the sum of £1000 remains on deposit.

THERE are but few persons, observes an American journal, who can help admiring a small flock of Bantams, for their proud sprightly ways are sure to gain them admirers, and this feeling is shared by age and youth alike. As a present to a boy or girl no better one can be given than a pair of Bantams if they have the room to rear them, which need not be large, for a small yard will be ample space for them to exercise in, while the amount of food they consume is so small that it is not noticed, the scraps from the table keeping them abundantly supplied. A house can soon be made from a large box, which can be ornamented as best suits the taste and convenience of the owner. One desirable feature in regard to Bantams is that they are eminently useful pets, for they are invariably good layers, no matter what the breed, and their small plump bodies are more delicious eating.

WORKER BEES SETTING EGGS—FERTILE WORKERS.

AT page 420 of this Journal your correspondent "A RENFREWSHIRE BEE-KEEPER" says, "Under like favourable circumstances, after many years' observation, we have never had the good fortune to see workers setting eggs or yet met with any bee-keeper who had. Being so profoundly ignorant of the matter I would be delighted to receive information how it is gone about." Some years ago, whilst conducting experiments with a hive which was swarmed artificially, I found that the bees removed a great number of eggs from a sheet of worker comb and placed them in another large sheet of drone comb from which they reared drones. How it is gone about I cannot say. The removal of the eggs took place after the removal of the queen from the hive.

About three years ago fertile workers were very abundant in Aberdeenshire; so much so that I offered a prize of 21s. for the best specimen of a fertile worker, to be exhibited in an observatory hive. No sooner was the schedule issued than I received many letters informing me that there would be a keen competition for my prize. One bee-master wrote to say that he had the bee wanted, and would of course exhibit her; "but," said the writer,

"if she perish before the day of the exhibition I will obtain one from the south, as they are very abundant about Lanarkshire." The day of the exhibition came, but to my great disappointment there was not a single exhibit. I asked several of my correspondents why they did not bring their fertile workers; the invariable answer was, "she died." Since then I have not heard of any fertile workers in this county.—A. COCKBURN, *Aberdeenshire*.

SWARMING AND NON-SWARMING.

MR. A. PETTIGREW is very far wrong on page 160. The clergyman had 445 lbs. super honey from eight Stewarton stocks, which, had he sold at his own door, as I did mine, at 1s. 6d. lb. comes to £33 7s. 6d.—equal to a dividend of £13s. 5d. from each stock without run honey or touching his capital. The thatcher had 64 lbs. super honey from five straw skeps, which at 1s. 6d. lb. comes to £4 16s., or a dividend of 19s. 2d. each stock; but Mr. Pettigrew, like some bank directors, to give the appearance of a big dividend melts up the entire capital of the five stocks into 350 lbs. run honey at 1s., or £17 10s.; this added to the dividend of £4 16s. makes £22 6s., or £4 9s. 2d. each in value, principal and interest. My Stewarton stock gave me £5 2s. of interest for capital invested, and, like the clergyman's, remains to work for me another year.—J. R.

REMARKS.

11th.—Cold with snow until 5 P.M.; moonlight night. Lunar halo 9 P.M.
12th.—Very cold and thick all day; dark very early in afternoon.
13th.—Bright and clear in early morning; sharp frost; little sunshine in morning, overcast and rather foggy after 3 P.M.; starlight night.
14th.—Clear, bright, and very cold day; starlight night.
15th.—Sunny morning, a little soft hail fell at 1 P.M.; thick snow for a short time afterwards; overcast evening.
16th.—Misty morning; dull and very dark all day, with sleet and snow. Partial thaw.
17th.—Fine and brighter day, but very cold; starlight evening.
An extremely cold week, more than 16° below the average. The cold, however, has been persistent rather than intense, as we have at present had no minima at all nearly as low as in 1860 and 1867. The total fall of snow is as yet quite insignificant.
18th (9 A.M.)—Rapid thaw, temperature 37°.—G. J. SYMONS.

COVENT GARDEN MARKET.—DECEMBER 18.

THERE is little alteration in our Market except among vegetables, the recent frosts checking the supplies considerably.

NOTES ON HOLLIES.

THE high estimation in which the Holly is held by all classes of society for decorative purposes at this festive season, together with the charming effect well-grown specimens at all times display, render it one of the most valuable of evergreen trees or shrubs, while its usefulness when planted thickly together for forming hedges surpasses anything else our gardens possess.

The common green form, *Ilex Aquifolium*, is a native of our own country, and is commonly to be met with growing in the deepest shade as well as in more open and sunny positions. The dark green glossy foliage and natural pyramidal habit of the shrubs are in the summer time very attractive, but when loaded with clusters of deep coral-red berries at a season when the garden is destitute of brightness the shrubs show to great advantage. Even were common green Holly the only variety that we possessed we should doubtless be proud of it; but by the aid of art we have now a host of beautiful and graceful forms that adorn our ornamental grounds as specimens, standards, bushes, pyramids, and weepers. We have them with golden and silver variegation in great variety and in numerous shades. We have trees with foliage bristling with spines, while in others the foliage is perfectly smooth: each and all are beautiful objects for lawn and garden adornment.

My intention in this paper is only to direct attention to those Hollies that are most prominently cultivated, and which are generally met with in smaller collections, carefully noting the purposes for which some varieties are better adapted than others.

HEDGES.—Where soil and situation are suitable the common Holly grows rapidly, bears clipping with impunity, and makes the most impenetrable, and at the same time ornamental, hedge of any shrub in cultivation. The best method of planting a hedge is to trench deeply a space about 3 feet wide, to add manure liberally, and to plant young established bushes not less than 18 inches or 2 feet in height, and about the same distance apart from plant to plant. The first season they will do no more than take fair hold of the soil, and will require no more attention than keeping weeds down and giving now and then a good soaking of water if the summer is very dry. The second year they will have made considerable progress; a few for the side growths may then be removed, but the leading growths must not be cut. Repeat yearly the same operation until the hedge has attained 7 or 8 feet in height, when it may be regularly topped and cut into the desired shape. About every 20 feet a strong leader may be left, which will in a few years bear berries abundantly; or the practice may be adopted of budding a strong-growing variegated variety in the common leader left, so that in course of time you become possessed of a dark green hedge with gold, silver, and other variegated heads placed at regular intervals. Hedges worked in this manner when well furnished have a remarkable effect. A good time for clipping Holly hedges

is as soon as the growths are nearly ripened, which in the south is generally about the middle or end of July. The hedges are then neat until the following summer. Some hedges planted here ten years ago are now quite 8 feet high and as perfect as could be wished for, and these during the first five or six years after planting had nothing done to them beyond keeping them free from weeds, clipping the growths slightly at the sides, and removing the tip of any leader that had grown far ahead of the rest.

PYRAMIDS.—It is the natural habit of most varieties of Holly to form a pyramidal form, in which character they are very pleasing as single specimens; but a little assistance is sometimes requisite in training the leader upright and cutting-in the other portions to secure the desired shape. With a very little manipulation of this kind splendid trees may be had from 20 to 25 feet in height of all the robust-growing kinds. Perhaps the variety known as *Hodginsii* is one of the best and most rapid growers for this purpose. It has also bold and handsome foliage of deep glossy green 3 to 4 inches in length, deeply but tolerably regularly spined. The Golden, Bronze, and Silver Queens, Gold and Silver Milkmaids, *Angustifolium flavum* (yellow-berried), *Doddintonense*, *Handsworthianum*, *laurifolium*, *Maedriense*, and *ovata* are all suited for making good specimens.

BUSH SPECIMENS will include all varieties that are of a dwarf dense habit. The most notable of all Hollies for this purpose is *Waterer's*; plants of this splendid hardy and compact rich golden Holly generally grow into dwarf dense bushes without any assistance whatever; shrubs not more than 4 to 6 feet in height will often measure 13 and 14 feet in circumference. The leaves are medium-sized, oblong, smooth, and almost spineless, with a marginal band of deep golden yellow—altogether a very distinct variety, and ought to be in the most limited collections. *Ferox* (the Hedgehog Holly), and its varieties *F. foliis argenteis* and *aureis* are also very suitable for bush specimens.

WEEPERS.—These are worked on clear stems of various heights. Some few varieties possess a naturally weeping habit, the branches in a few years bending down to the ground and make most elegant specimens. A weeping variety of the common green form is very robust in growth and handsome when worked after this manner. *Perry's Weeping* is beautifully variegated, and is altogether a most attractive variety, as is also the new *Golden Weeping*.

STANDARDS.—Compact, round, well-balanced heads on clean straight stems from 3 to 6 feet in height can be easily obtained of nearly every variety in cultivation; but the Golden and Silver Queen varieties, as well as some of the choice green-foliaged varieties, are most generally grown in this form. The heads are regularly and methodically trimmed-in, and specimens are produced well adapted for a winter garden of evergreens.

Some of the variegated forms of the Holly have doubtless been in cultivation for a considerable time, as we now and then meet with large and lofty specimens of the Golden and Silver Queens as park trees, than which nothing can be more beautiful. We recently met with a fine old specimen of *Golden Queen* growing in the grounds of *Belvidere*

House, Wimbledon. Another very old specimen is to be seen at Coombe Wood House, on which estate all Hollies grow luxuriantly, a fact, we are told, which induced the late Mr. James Veitch to select the present site for the splendid nursery of hardy trees, shrubs, and Coniferae at Coombe Wood. A fine specimen of the common Holly growing there was left to adorn one of the finest avenues of Wellingtonias and Araucarias in the kingdom. This fine old specimen Holly is beautifully furnished from the top to the bottom, and is worth journeying a long distance to see. In the extensive specimen border of the nursery may be seen growing every variety of Holly in commerce, and as many of them are now laden with berries the shrubs form a fine feature in the picturesque grounds.

Variiegated Hollies occasionally produce green sports. These should be promptly removed, or they will soon gain supremacy, and in time ruin a beautiful shrub.

Hollies may be transplanted as well as most hardy shrubs, yet when the specimens are large and have not been disturbed for some years they should be prepared for removal by having the soil opened all round their balls during the previous summer, carefully severing any roots that protrude beyond the trench, then fill in the soil again, and by the following autumn they will be found to have made large masses of white young feeding roots. In this manner Hollies if carefully lifted can be successfully planted of very large size. May and the early autumn months are recommended as the best times for transplanting Hollies, but on light dry ground they may be removed any time during the winter when the weather is favourable.

Hollies doubtless thrive in almost all soils, but they make more rapid growth in warm dry subsoils, and to such who have moderate dry soil we advise them not to neglect to add any really hardy and distinct Holly to their collection. By the time that this appears in print the Holly will have been employed largely for the decoration of our homes and churches, and will contribute much to a bright and cheerful Christmastide.—J. W. MOORMAN.

TEA ROSES.

I HAVE read the letter of the "HEREFORDSHIRE INCUMBENT" on page 256 on Tea and Noisette Roses with very great interest, and as nothing that concerns these lovely flowers can be said without receiving much attention from myself I hope my friend will not feel hurt if I venture to offer a few remarks upon his article.

The list he gives is a most excellent one, but I am astonished to find that he omits one variety which he has, in my eyes at least, made peculiarly his own. I do not think I ever in my life but once (and that was a superb bloom of Souvenir d'Elise) saw so splendid a specimen of a Tea Rose as the Comtesse de Nadaillac he showed at Hereford. I ventured to remark upon it at the time, and to add my doubt as to its robust qualities. My friend in a recent article assures me I am mistaken on this point, and that this Rose is as vigorous a grower, at least in his soil, as any other Rose, yet, strange to say, he does not include it in his list of twenty-five Teas and Noisettes. This I am convinced is an oversight, but it will be well that the public should know that this is the case.

I then come to a most strange matter. If I am wrong, then I have not only been wrong for ten years, but I have never had the slightest hint given me that I was in error. But surely Souvenir d'Elise and Souvenir d'Elise Vardon are the same, just as Madame Montague and Madame Montague Remauri are the same pianists, Madame Trebelli and Madame Trebelli Bettini are the same vocalists, yet the "HEREFORDSHIRE INCUMBENT" boldly puts them down as two different Roses, each so good as to be worthy of a place in his twenty-five.

I entirely agree with him as to Madame Bravy being distinct from Alba Rosea or Joséphine Malton, for the first-named is much fuller at the centre, and the petals are folded more closely, more like Comtesse de Chabillant in form than the other; but I think that Mesdames Bravy and Sertot are at least Siamese twins. Julie Mansais with me is a most lovely Rose; it opens easily, and though somewhat small as a rule is often large enough for an exhibition stand. I do not know what I should have done without it this year. It is, however, a very poor grower. Another Rose I think highly of is Jean Pernet. I have cut blooms of this almost equal to Cloth of Gold, and I shall always grow it, if for nothing else, on account of its lovely buds.

Some of the Tea Roses mentioned by the "HEREFORDSHIRE INCUMBENT" are unknown to me, and I shall try to procure this autumn Comtesse Riza du Parc and Madame Camille, for the addition of one good Tea Rose is a great event in my life, and I will accept my friend's recommendation on this point as being very valuable; at the same time I will venture to give my selection.

CHRISTMAS DESSERT.

FOREMOST place must be given at this festive season to the king of fruits—the

Pine Apple, garnished as it is with leaves of its own at the base of the fruit, and crowned by a towering rosette of its distinct foliage. Smooth-leaved Cayenne, from its imposing appearance, is most desirable. Black Jamaica is less noble in appearance, but notwithstanding is not surpassed for quality at this season of the year. Queen is also good, and so is Enville.

Grapes come next in their rich golden and purple tints with blooms that proclaim them the queen of fruits. As imposing dishes are desirable at this season, therefore come out now with the Gros Guillaume, which for size of bunch has no equal amongst black Grapes; but Gros Colman outstrips it for size of berry, and altogether a more taking contour. Forget not quality, but put forward Madresfield Court, splendid alike in size, symmetry, and flavour. Lady Downe's is the better for being kept until the new year, along with Mrs. Pince, that is apt to colour badly at the shank and shrivel at the "nose" unless thoroughly ripened. Alicante in its jet and West's St. Peter's in its purple lustre make their presence felt in the best of company. Add to the purple the gold, but do not mix them; they tell best apart. Calabrian Raisin, Trebbiano, and Syrian have big bunches and make their mark; Waltham Cross, with its monster berries, is effective; Tokay, not often seen now-a-days in its amber, is superb; not forgetting to link the old and new year together by bunches of the most esteemed Grapes—viz., Black Hamburgh and Muscat of Alexandria. They do well together, usefulness being then combined with the highest quality. Black Grapes show best in "frost." Sprays of Ice Plant, which may be kept in a pit from which frost is excluded, answer well for garnishing, and Stachys lanata sprays are little inferior. A few berries of Nertera depressa greatly enliven the "frost" or "hoar," and so do the berries of the Snowberry and white-fruited Euonymus europæus, the opening capsules of which are very beautiful. Vine leaves are always appropriate for ornamentation; failing a supply of them some of the Abutilons, as Sellovianum mar-moratum and S. Thompsoni, are serviceable. Cissus leaves set off white Grapes advantageously with a few sprays of Ice Plant and a few coral berries of the Cotoneaster and Butcher's Broom.

Oranges are indispensable for Christmas dessert, having a peculiar charm if homegrown, large, well-ripened examples are displayed with their own foliage, the fruit being with a portion of wood. But Oranges as grown upon trees barely kept alive are of no use whatever for affording fruit for dessert. Trees for that purpose require a high temperature and plenty of atmospheric moisture; indeed they require as high a temperature as hothouse Grapes, and instead of allowing to go cool in autumn and early winter the house should be kept warm, and after the fruit is well advanced for ripening rather dry, 55° being a minimum at that time; better 60° to 65° by artificial means until the fruit is ripe. Foreign Oranges in this country at this season are not fit to be named with home-grown produce when the trees have proper treatment. The Tangierine is a delicious little fruit; St. Michael's with its thin rind and the Maltese Blood are excellent, and many others, the Egg Orange being quite novel in form and with a juice sweet and refreshing. All should be displayed with their own foliage.

Melons afford a good addition to the dessert. Fruit that ripened late in the season will often keep for a lengthened time in a temperature of about 50°, but are preferably cut just before ripening with a portion of wood, and placed in a vinery where the Grapes are ripe or in a rather dry fruit room. Little Heath is one of the best for this purpose, and the Persian class also keep well. The best of all for Christmas is the Cabul, a large oval fruit of a bright yellow colour when fully ripe; and Khiva is admirable for the same purpose. Garnished with sprays in wreath form of *Passiflora trifasciata*, dotted with the fruit of *Passiflora cærulea*, Melons, whatever may be the flavour, are very effective in appearance.

Pears come to the fore at this time; their russet hues contrast admirably with the shining Grapes and glossy Oranges, though some of them are not wanting in colour. *Beurré Clairgeau*, which unfortunately may not always be kept until this time, is very beautiful; *Forelle* (spotted like a trout) and *Durondeau* (with its splendid colour) unfortunately ripen earlier than this, but they may be kept in earthenware jars in an ice house or cold cellar. Setting those aside we have *Huyshe's Prince of Wales*, *Beurré Sterckmans*, *Beurré d'Anjou*, *Easter Beurré*, *Winter Nelis*, *Glou. Morceau*, *Beurré d'Aremberg*, *Joséphine de Malines*, *Passe Colmar*, and *Knight's Monarch*, which are available at this time. *St. Germain* and *Chamontel* have an imposing appearance, but require a warm soil and to be grown against a wall, or the quality is inferior. Pears may be effectively dressed with small Laurel leaves, preferably sprays with fruit, giving prominence to Portugal over common Laurel. The rich berries of *Pyracantha*, *Cotoneaster*, *Briar heds*, *Japan Quince* (*Cydonia japonica*), and *Siberian Crab* heighten the effect of Pears wonderfully.

Apples come out in strong force. Every housewife keeps back her best for distribution at Christmas. *Api* or *Lady Apple*, though small, is very beautiful; *Cox's Orange Pippin* is scarcely less so; *Court Pendu Plat*, *Margil*, *Pearson's Plate*, *Golden Reinette*, *Golden Pippin*, *Wyken Pippin*, *Scarlet Nonpareil*, *Ashmead's Kernel*, and *Golden Harvey* are all small fruit, but beautiful for the most part in appearance, and are all of high quality. *Ribstone Pippin* is an advance in size over the preceding, *Claygate Pearmain*, *Lord Burghley*, *Cockle's Pippin*, *Golden Russet*, and *Ross Nonpareil* represent half a dozen of the middle-sized Apples of great excellence; and large Apples are represented by *Northern Spy*, which requires a wall to grow it perfectly, *Dutch Mignonne*, *Reinette du Canada*, *Blenheim Pippin*, *Lewis's Incomparable*, and *Lady Henniker*. Some like a soft Apple. *Beauty of Kent* will suit that taste, and please everybody by its very handsome appearance. All the small Apples may be set with sprays of *Cotoneaster* in fruit and haws set in Laurel greenery, the large fruit having a foil of Laurel dotted with *Fairy Apple* in clusters. Heds, and especially berried sprays of *Pyracantha*, are appropriate for setting up Apples.

Nuts must be included (*Filbert*, *Cob*, and *Walnut*), which may be draped with sprays of *Garrya elliptica* with its catkins or sprays of *Evergreen Oak*. The *Filberts* will, of course, be in the husk, but the *Walnuts* should be clean, and if dried the Nuts should be placed in water for twenty-four hours, when the skins will then peel off well, nearly equal to those kept in moist sand.

Medlars complete the list of fruit available for Christmas dessert in most establishments, and they may be dressed with evergreen Thorn sprays, berried of course. More rare are the following:—

Banana (the fruit of *Musa Cavendishi*) is a grand addition to the dessert, and is not an infrequent one in large establishments; but it is difficult to time the fruiting so as to come in just when wanted. Yet suckers in good heat under liberal treatment produce fruit within the year, and the fruit will keep for six to eight weeks after being ripe, cutting off the spadix with a portion of the stem just where the upper tier of fruit is ripening, keeping it in a dry airy room after the manner of late Grapes.

Guava is another fruit not generally cultivated, probably from the fact that the plants in a young state do not bear freely, but when a little aged they bear well, producing fruit in long succession often during the winter months. The purple fruit is well set off by garnishing with foliage and fruit of the *Strawberry Tree* (*Arbutus Unedo*), which do good service also for Bananas.

Grandifolia (*Passiflora quadrangularis*).—Fruit may sometimes be had by fertilising the flowers about August, but they do not set well at that season. *P. edulis* is more accommoda-

ting, setting much more freely; but the fruit is not nearly so large. We have occasionally had fruit of *Tacsonia mollissima*, which is whitish yellow and about the size of an egg, ripening unfortunately in October or November, though occasionally later, and keeping up to this time. They take the eye, the less said about the palate the better. Set up in the leaves of some palmate *Passiflora*, and if the small yellow fruit of *P. cærulea* be dotted around, or the Cherry-like *Cape Gooseberry*, the effect is good. *Tacsonia Van-Volxemi* often is plentifully furnished with fruit at Christmas, but they are not so inviting in appearance as the others, and are simply abominable eating unless ripened in a temperature intermediate between a greenhouse and stove; in fact, these and some others require more heat when ripening than during growth, and then their quality is a little better.

Ugni, the fruit of *Eugenia Ugni*, is desirable if only for its aromatic flavour. It ripens well in a greenhouse, and treated like the *Myrtle* flowers and fruits freely. Set in its own spray, berried of course, the effect is admirable, *Snowberry* berries enlivening them wonderfully.

Pomegranates do not fruit freely in this country as usually grown—viz., against walls, but in an orchard house fruit is occasionally had, and in a heated one with certainty; or with the treatment of cool Grapes fruit would be had as we have seen, but only in one instance—viz., at Well Head, Halifax. They appear best put up with *Myrtle* sprays with their purple seed vessels.

Shadocks have a splendid appearance, requiring the same treatment as Oranges, though, like Lemons, they are not so heat-requiring to secure them, but are all the finer for it. Their own spray is a good set-off, heightened in effect by berried sprays of *Skimmia japonica*.

Strawberries are a good addition. Early-forced plants planted out or, if kept in pots, potted and plunged in an open situation, abundantly supplied with water and housed in late September or early October, affording light airy situations in a house with a temperature of 50° by artificial means, will afford fruit late by a little careful management at this season, the latest-forced plants keeping up the succession, and *Sir Harry* and *Vicomtesse d'Horcart de Thury* swell well late in the season. Alpines sown in spring will afford fruit in winter, and form admirable margins to a dish of larger fruit, setting the Alpine in their own leaves with the fruit in trusses.

Christmas desserts often comprise *Litchees*, *Pomeloes*, *Prickly Pears*, &c., but these can only be obtained from good fruiterers.

I may fittingly close this paper by a brief allusion to plants suitable at this season for table decoration. *Holly* and *Mistletoe* are out of the race for such purpose—theirs is of another character which it is not my purpose to treat. Berried plants are, however, suitable for table decoration at this season. *Ardisia crenulata* with its bright red berries, and the white variety, *A. crenulata alba*, are superb. *Rivina humilis*, with its clusters of red or purplish berries, is very effective. *Calli-carpa purpurea*, with its purple berries, is a neglected but very useful plant. Standard *Otaheite Orange* and *Solanum Capsicastrum* in good fruited examples are very fine. Some of the *Capsicums*, as *Prince* and *Princess of Wales*, are highly effective. There are many plants that might be pressed into the service mostly of a hardy character. Such, however, do not fruit freely enough in small plants. I will close my notes by pointing to a centre for the table of *Variegated Pine* (*Ananassa sativa variegata*), which in fruit is one of the most striking of all table plants.—G. ABBEY.

THE GARDENER'S FOOT.

"WELL, Edward," said I, talking to an old friend as we walked around the garden together, "you have a nice place here, and things grow well. No slugs and snails, eh! like I have; not many birds either to do much damage. Now tell me," said I laughingly, "what does most mischief in your garden." "You will never guess," said he, and a gloomy look came over his otherwise cheerful face. "Don't know," said I, "give it up." "Well," said my dear old friend, "I can trap the slugs and snails, scare the birds, kill the green fly, prevent mildew, burn off the lichens from my trees with lime and soot, but I lose many plants for all that." "How?" said I. "Well," said he, "By the gardener's foot! Yes, the gardener's foot is one of my worst enemies. He walks on my flower beds just as he would a gravel walk, heedless of where his foot goes. In the early spring smash go my plants just peeping through the soil. Twigs and sprays are broken off

my shrubs and plants by his heedless ways, and yet—and yet," said my friend, "he is a very good gardener; but he is not like me, he does not love his plants as I do."

"That is just it," said I, and as I walked home I thought how often—oh! how often—I had seen my own gardener stand on one of my best beloved plants. In fact, I had one gardener who, whenever I went to talk to him, invariably went on the flower bed, as if he felt then on his own ground, and only the path was mine! I lose quantities of good things year by year by being trodden into the earth. I had one plant that I was choice of in particular. I went to look at it last week to see how it got on, but the gardener's heel had got the start of me. There was the mark, and my dear little one scarcely visible, with its heart crushed out.

It is no new thing that I write about. All who have borders know it, feel it, grieve over it. Talk to your man how you will, gently, kindly, loudly, or softly, the result is just the same—he does not mind where he puts his foot. He says, "Oh! yes, I'll mind, I'll be careful," and at the moment he is standing on your only *Aquilegia chrysantha*. When gardeners love the plants under their care, as true gardeners should and do, they will then mind where they put their foot. They will look on every plant as their children, love them and nurse them as such. I do. Hoping this will meet the eye of my friend's gardener and my own, besides that of others that I know, I conclude, wishing and hoping for better times—times not so crushing.—CYRIL.

THE LATE EXHIBITION OF THE NATIONAL CARNATION AND PICOTEE SOCIETY.

ON page 444 "*D., Deal*," says, "I was talking the other day to one of the exhibitors, and a very good grower and dresser of the Carnation and Picotee, when he expressed his surprise at the position which one of our southern growers occupied, and he attributed his inferior position entirely to his mode of dressing. He said, 'I have always thought his style of dressing—that of bringing them up full in the centre, the best; but the winning flowers were dressed much more flatly. I was told this was the northern style, and as I believe the Judges were northerners it is easily accounted for.'"

One may wonder that upon a matter so easy of solution as the question whether the Judges at the late Show were northerners or not, that your correspondent did not at least expend a postcard before promulgating the opinion of the good grower and dresser, whoever he may be, and thus adding to the list of myths his imagination or ready credence of unfounded rumour has given currency to.

The Judges acting at the late Show of the National Carnation and Picotee Society were—for the open class, Mr. Thomas Moore, Mr. Richard Gorton, and Mr. Wm. Hewitt; for amateurs, twelve-bloom classes, Mr. Charles Turner, Mr. John Ball, and Mr. Jonathan Booth; six-bloom classes, Mr. Douglas, Mr. George Rudd, and Mr. E. S. Dodwell; for single specimens, Mr. Simonite and Mr. Lord.

Of the opinions of "*D., Deal*," as to dressing Carnations and Picotees I have nothing to say beyond commending the readers to the excellent and practical remarks of Mr. Farren on page 443, and stating the fact that there is not a solitary exhibitor of these flowers, and, I believe, no one entitled to be called a grower, who is not utterly antagonistic to the views "*D., Deal*," has expressed.

With "*D., Deal*," I see with great pleasure the communication from Mr. Slater, especially as Mr. Slater so honourably recants opinions he formerly expressed, and admits the evils he feared have never been produced. I wish I was able to say Mr. Slater's circumstances were as comfortable as could be desired for his great age; but as that is unhappily not the fact, I hope I may be permitted to say that the bounty of any reader of this paragraph will be gladly received and dispensed for Mr. Slater's benefit by Mr. Samuel Barlow of Stakehill House, Chadderton, Manchester, and it will be a source of great satisfaction to me if this reference shall add to Mr. Slater's much-needed comfort.—E. S. DODWELL.

CARBOLIC ACID AS AN INSECT KILLER.

MY experience teaches me that sulphur, no matter how used or in what form—*i.e.*, either dusted on the affected part or painted on highly heated hot-water pipes, is in no way fatal to red spider. In spite of all known precautions and care last year, both my Cucumber plants and Vines were most terribly

infested last summer with the ravages of this destructive pest. My belief, the result of experiment is, that carbolic acid water not too strong, say one part of the acid previously dissolved in an equal bulk of glycerine, and then diluted with about forty parts of pure filtered water, and either used as spray to the leaves, or even used by means of an ordinary garden syringe, is as certain an insecticide as sulphur is an antidote for mildew.

But my reason more especially for writing to you is to ask for the following information—*viz.*, is it your opinion that the solution of carbolic acid I have named, and used as I have stated to the surface of the infested leaves, proves in any way injurious or detrimental to the health or well-being of the Vines? And further, would adding carbolic acid to the paste used for dressing the rods, or the use of carbolic acid soap in washing the woodwork and glass of the vinery, prove detrimental either to the Vine rods or the young leaves as they arrive? I am convinced that carbolic acid is the surest insecticide and preventive that can be used; and if it does not prove injurious—and I opine it will not—we have in carbolic acid a remedy which will surpass all others, and prove an incalculable boon to all Grape-growers.—W. E. B. A., *Faversham*.

CHRISTMAS VEGETABLES.

ASPARAGUS, French Beans, Mushrooms, Seakale, Rhubarb, Tomatoes, Broccoli, Brussels Sprouts, Cabbage, Savoy, all kinds of roots, and plenty of Celery, Lettuce, Endive, Mustard and Cress, Radishes, Chicory, and Cucumbers, are the principal vegetables from the kitchen garden with which we are furnishing our employer's table during the Christmas week. Most of these vegetables have been referred to before in these pages by me, but now that we are in the midst of them I may say, with a little care they are produced easier than many suppose.

Asparagus we can never have too much of. Next spring we shall plant about half an acre with two-year-old plants of it. This will supply us with forcing roots for several years. What we are cutting now is growing in the bed of a Melon pit; 3 inches of soil is spread out on boards, below which there is a flue. The roots are packed close together above the soil and just barely covered over. With a top and bottom heat of about 60° and plenty of water it grows freely and luxuriantly.

French Beans.—Osborn's and Fulmer's Forcing French Beans are fruiting in 8-inch pots on a stair-like stage at the back of the centre pathway in the same house. We fill a number of pots every two weeks and are never without Beans. Those which we are gathering from now, however, are growing in cutting boxes 2 feet long, 1 foot wide, and 4 inches deep. The seed is sown in 3-inch pots, five and six seeds being placed in each pot, and as soon as the young plants are about 3 inches high they are turned out of the pots and planted in the boxes, eight and ten potsful are put into each box. They thus fruit equally well, and do not take half the space up as those in pots. French Beans are a great delicacy at Christmas as well as during the whole winter, and they have as good a flavour now as in summer.

Mushrooms are quite indispensable as a winter vegetable. They are easily cultivated provided the spawn is good, without this no one will grow Mushrooms. As the horse droppings are gathered daily at the stables they are emptied in an open shed and allowed to lie there until there is a good cartload, when they are brought to the garden, spread out again in an open shed for a few days or a week, as they may be wet or dry, and are then made into a small bed in the Mushroom house. We never make the bed more than 10 inches deep, but this thickness is made very firm. Little pieces of spawn are dibbled in 3 inches deep and 6 inches apart when the heat in the bed is about 80°. When the heat is likely to go down quickly the spawn is covered over at once, 2 inches of soil from any of the kitchen-garden quarters is spread over and beaten down firmly all over the surface of the bed. As a rule the Mushrooms appear about five weeks after this has been done, but sometimes they do not come for six and seven weeks. Mushrooms may be grown in any dark shed or cellar where the heat ranges from 55° to 65°.

Seakale and *Rhubarb* will do in the same place and with the same heat, but they should have a little bottom heat as well. The Rhubarb takes three or more weeks longer to come up than the Kale, and allowance should be made for this when the roots are put in. The quicker the Seakale is forced the more tender it is, but at the same time a temperature of 65° should never be exceeded, as more heat than that makes

the produce tough. Good roots always force quickly in moderate heat.

Tomatoes.—A portion of our supply for Christmas were cut green from plants against the open walls during October, hung up in a cool airy vinery, and allowed to ripen at their leisure. This is a cheap and good way of securing a late autumn supply of fruit; but in case of failure we have several young plants which came into fruit in October bringing many clusters of fruit forward in a Pine house. Vigorous young plants when kept clean fruit as well in winter as in summer. Ours never have more heat than 65° and some nights as low as 40°.

Broccoli.—If ever I said anything good about Snow's Winter Broccoli in the *Journal of Horticulture* I now beg to withdraw the statement. For the last two years it has not come in with me for two or three months after the time it was represented to come in. December is its time, and I have had it come in well at that time, hence my once favourable impression of it; but last year it turned in early in March. From many other kitchen gardeners I hear it is very shifty in this respect. Veitch's Self-Protecting Broccoli is our best Christmas variety this year, and a capital one it is. We have been cutting it since September, and I think with a little scheming in having a good batch of successional plants of it the supply would be unbroken from September until April. I advise all to grow it largely for winter supply.

Brussels Sprouts.—Another season's experience confirms previous impressions that to do this crop full justice the seed should be sown on or before February 1st. Our best were sown on that date in a cold frame and planted out in their permanent quarters early in April.

Celery is plentiful and fine, although planted on a heavy piece of ground; but when the trenches were made dung and loam chopped up and mixed together was placed 6 inches thick at the bottom of the trenches, and it has answered the purpose well. Although the summer was excessively dry water was never applied, and out of two thousand plants not one has "bolted."

Lettuce and Endive are lifted and placed in a dark dry shed to blanch about a fortnight before they are wanted in the pantry. Besides blanching them this is a good plan to have them convenient in stormy weather. Small boxfuls of Mustard and Cress are sown twice a week to keep the supply going. It grows rapidly in a heat between 50° and 60°. The Radishes we are using now were sown during September in spent Melon and Cucumber frames. Chicory is lifted, the leaves cut off, six or eight roots potted in an 8-inch pot, and then set in the Mushroom house to make tender young leaves, which are a capital addition to the salad bowl.

Cucumbers.—We have grown many varieties during 1878, but as yet we have found none to equal Telegraph. It is the only one we have in fruit now.

Peas.—These and new Potatoes would have been added to our Christmas vegetables, but through some alterations in our culture we have none this season. However, they are of easy culture when space can be spared to grow them. The best way we have tried of having Peas now is to sow the seed like French Beans in 8-inch pots about the end of July, placing the pots in the open air and subsequently in a cold frame until cold weather sets in, when they may be placed in a cool vinery or Peach house fully exposed to sun and freely ventilated. Those of the Little Gem type are the best for pot culture, as they can be supported with small twigs like French Beans. Frost must never be allowed to touch them, and throughout they must be carefully attended in the way of watering. Not less than a hundred potfuls should be grown and as many more as possible.

Potatoes may be grown in pots under the same conditions as Peas. Three or four tubers should be placed in a 12-inch pot, using good soil, and covering the sets about 3 inches deep. They may also be grown in frames in the same way as they are in spring, only when planted in July they require no bottom heat to start them; but during October they must be protected from wet, and in November and December from all bad weather. We have planted Potatoes in March, lifted them in June, planted again in July, and lifted at Christmas.—A KITCHEN GARDENER.

LONDON NURSERIES AT CHRISTMAS.

LAST week Mr. Luckhurst remarked on the importance of the resources of the garden as affording indispensable Christmas cheer for British homes. Of the fruit and vegetables "in season"

others have written, and as to plants and flowers nowhere can they be seen in such variety as in the leading nurseries; hence the following brief—too brief notes and observations recently gathered at a few of the metropolitan establishments. First may appropriately be noticed the head quarters of the great firm of

MESSRS. JAMES VEITCH & SONS, CHELSEA.—At this establishment no attempt is made to arrange the various plants for spectacular effect, and the visitor to see all that is to be seen must traverse about a hundred houses and pits. He will first be taken to the Orchids—a collection remarkable for its excellence, its numbers, and its novelty, seeing that it stands alone as containing so many hybrids, which now and again startle by their value and beauty. A firm that can in the same year produce a Cattleya Veitchiana and a Calanthe Sedeni have much to be proud of; but it is not of the past but of the present that we will now refer. Many Orchids are flowering now; perhaps the most really beautiful is Cattleya exoniensis, but striking by its chasteness, grotesqueness, and purity is *Angraecum chalcidanthum*. A sesquipedale will shortly be in splendid condition, one of the plants having five spikes showing nineteen flowers, six flowers on one spike—a very unusual occurrence. Calanthes, as may be expected, are both numerous and fine. *Odontoglossums* Roezlii, a fine variety, and its pure white variety very chaste; also *Alexandrae*, *prænitens*, *Hallii*, *Insleayi*, *leopardinum*, *cirrhosum*, *luteo-purpureum*, *membranaceum*, *Rossii majus*, and *Warszewiczii*; Cattleya Skinneri, and the pure waxy white Skinneri alba; Vandas insignis, suavis, and tricolor; *Cypripediums* Schlumieri, a fine variety, insignis, and insignis Maulei, *Harrisianum*, and the almost ever-flowering Sedeni. C. Laurenceanum is attractive by its large and richly-marked foliage apart from its flowers, and so also is C. marmarophyllum. Flowering now also are many varieties of *Laelia alba*, and the larger L. a. Bella; also L. autumnalis and L. anceps, and the more rare L. acuminata. Amongst Dendrobies we noticed D. superbiens, D. heterocarpum, with its primrose colour and perfume, and D. inocharis; and striking, although not yet in flower, are the splendid growths of D. crassinode, the plants being grown in shallow saucers. *Cologyne cristata* is showing fifty spikes and will shortly be a charming sight. *Oncidium Forbesi*, very fine, and crispum; *Sophranites grandiflora*, a brilliant mass; Vandas, Masdevallia toverensis, and Cattleya Loddigesii superba, *Phalaenopsis grandiflora*, *Epidendrum dichrosum*, *Pilumnea fragrans*, and *Cymbidium Mastersii* also share in the aggregate display.

In other houses several plants, beautifully variegated, of the useful and hardy *Aspidistra lurida* variegata attract notice; as also does a remarkable collection of *Daphne indica rubra* in 4-inch pots, the plants only being a few inches high, clothed with green foliage and studded with fragrant flowers. Another fragrant plant that will shortly be in flower is *Boronia megastigma*, of which there are many hundreds in various sizes. A houseful of Tree Carnations in all the best varieties show how valuable these plants are for winter decoration. *Ericas* Lambertiana, *hyemalis* superba, and others are effective, not forgetting the bright scarlet *cerinthoides coronata*. *Monochætum ensiferum*, flowering freely, has been injured by the fogs; but *M. sericeum multiflorum* equally fine, is perfectly fresh. *Ipomæa Horsfallii*, flowering in small pots; *Cyclamens* a fine strain; *Primulas* single and double, *Justicias*, *Eranthemums*, *Plumbagos*, &c., are also represented, and early Camellias are just expanding. The plants of these both planted out and in tubs are splendid and will eventually produce a fine effect. Many other plants are necessarily passed.

Alterations and improvements are being continually made in this nursery, the latest and greatest being the new seed stores just completed to meet the ever-growing demands of this important department of a business, the magnitude of which few visitors can fully appreciate.

MR. BULL'S NURSERY AT CHELSEA.—Passing through an avenue of lofty Tree Ferns and imposing Cycads remarkable for their stately and sober beauty, the visitor is conducted to a rich display of Orchids, their colours perhaps appearing the more bright in contrast with the great mass of greenery of the plants above noticed. The Orchids are effectively grouped, and produce an unquestionably beautiful Christmas show. Most prominent by its stately growth and fine spikes of rosy purple flowers, many of the petals wired with white, is the valuable Australian Dendrobe, D. superbiens. The Bamboo-like growths of this Orchid, 3 to 4 feet long, bearing near their summits fine spikes of partially drooping flowers, command, and justly so, the admiration of all visitors. Several plants are flowering, producing a mass of nearly twenty spikes. Not only is this Orchid intrinsically beautiful, but it can be easily

grown—not requiring a special structure nor a high temperature. It is remarkable also for the long-lasting quality of the flowers, they, under favourable circumstances continuing fresh for a quarter of a year. Such a combination of desirable qualities must render this plant very popular, and will create a desire on the part of many cultivators to obtain it. Other Orchids in beauty at the time of our visit were *Lælia anceps* and *L. anceps alba*, which has been recently certificated; *Odontoglossum nebulosum*, a remarkably fine variety; *O. vexillarium* roseum, rosy lilac and very beautiful; *O. Rossii majus*, *O. madrense* and *O. Alexandræ*. *Oncidiums* were represented by *O. Weltoni*, a fine variety, and *O. triumphans*. Charming by its chaste pencillings and pure white margin was *Cattleya maxima*; and very rich were *Masdevallia Harryana cærulea* and *Sophronites grandiflora*. *Cattleya Skinneri*, *Zygopetalum Mackayi majus*, *Philumena fragrans*, the curious *Bollea celestis*, *Cypripediums Sedeni*, *Harrisianum* (a fine variety), *insigne Maulei*, and *Vanda cærulea* were all in excellent condition, and dozens of fine spikes of *Calanthe Veitchii* and other varieties contributed greatly to the attractiveness of the house.

But while the Orchids in flower are naturally the more immediately noteworthy, Orchids out of flower are imposing by their numbers. A large house is filled with *Dendrobium nobile*, and “over the way” several houses in the new nursery are occupied by recent importations of these growingly popular plants. New plants in considerable variety, some beautiful, some curious, command a share of attention, and particularly striking is a houseful of *Dracæna Goldieana*. *Crotons*, *Palms*, and *Ferns* in almost all sizes contribute in an important manner to the general effect; and in contrast are potfuls and boxfuls on the stages and under them—wherever space can be provided—it may truthfully be said, scores of thousands of the valuable commercial plant the Liberian Coffee, which are grown to meet the great demand for exportation. Thus the nursery is interesting as well as attractive.

MESSRS. E. G. HENDERSON & SONS.—Unmistakeable signs of the near approach of Christmas were manifest on our visit to the Pine Apple Nursery. In the forecourt near the large conservatory Christmas trees were arranged—handsome Spruces ranging from 6 to 18 feet in height, the firm having a great demand for such trees. The interior of the large building is extremely attractive, very great improvements having been effected in the arrangement of the plants, and sound judgment having been exercised in selecting those that are best adapted for the adornment of such a fine structure as this is. The house, however, is not brilliant: indeed flowers play a small part in its embellishment, yet the effect is most pleasing from the free, natural, and picturesque manner in which the plants are arranged. Towering above all are two magnificent specimens of the Abyssinian Banana—*Musa ensete*. Although only planted two years ago, one of these plants is now 25 feet in height, the stem near the ground measuring nearly 6 feet in circumference, and the leaves, without the bare leafstalk, being 13 feet long. These noble specimens have a most distinguished effect. In fine contrast are handsome Tree Ferns, Fern-clad rocks, aquariums, stately *Araucarias*, *Palms*, *Yuccas*, and *Agaves*, relieved by such variegated-foliage plants as *Euonymuses*, *Euryas*, and variegated *Ivies*, and further brightened by flowers—*Ericas*, *Primulas*, *Hyacinths*, *Cyclamens*, and other flowers incidental to the season; and the visitor cannot fail to admire a remarkable specimen of *Aralia papyrifera*, which is flowering freely.

The other numerous and extensive glass structures are crowded with plants, many of them very rare, others beautiful, and all healthy. Orchids are in large numbers, the beautiful *Dendrobium Wardianum* having made remarkable growths which are studded with flower buds. These plants will shortly be a fine feature in the nursery. One or two of them are already in flower, and the others will follow rapidly. The collection of cool Orchids merits notice. The fire heat was applied to the house from April to the third week in October, and no plants could look more healthy. *Odontoglossums* are throwing up their spikes with great freedom. The night temperature of the house is now 45°, and it is worthy of remark that such plants as *Cymbidium Masteri* and *C. eburneum*, also Indian *Crocuses* (*Pleiones*), are flourishing in the most satisfactory manner under this cool treatment. Several Orchids are in flower which we cannot enumerate, but one not frequently seen is *Gomezia recurva*. The plants growing in the shells of the Brazil Nut (*Bertholletia excelsa*) have an unique effect. Amongst other flowers there are Tree Carnations in thousands—a wonderful collection; double *Primulas*, for which the firm

is famed; *Bouvardias*, which are largely grown; *Jasminum grandiflorum*, very useful for cutting; and not less useful the White *Azalea narcissiflora*, which is extensively grown; several *Amaryllises*, including the charming *A. O'Brieni delicata*, pure white striped and spotted with delicate rose. It is the result of a cross between a variety of *A. pardinum* and *Hippeastrum reticulatum*, and is a decided acquisition. Many thousands of *Amaryllises* are grown, and the collection of Cape bulbs is very extensive. *Sonerila Hendersoni* var. is a charming dwarf plant for this season, with rosy lavender flowers; and very striking is *Hæmanthus albo-maculatus*, with its pure flower heads and attractive foliage; and especially so, but of a different order of beauty, is *Tydeæ Robert le Diable*, with its large, numerous, scarlet and almost black flowers.

These flowers—with a fine collection of Ferns, *Anæctochilus*, *Crotons*, and other fine-foliaged plants—render the nursery particularly interesting. Improvements are being effected on an extensive scale, and the nursery is highly worthy of note and inspection.

MR. B. S. WILLIAMS, HOLLOWAY.—Visitors cannot visit this great northern metropolitan establishment at any time without finding much to admire. In the height of summer and the depth of winter flowers are always present, with plants remarkable for their high culture, rarity, and beauty. At this period of the year the most beautiful flowers are of course found in the Orchid houses, and there they are provided in plenty. *Calanthes* are represented by hundreds, *C. Veitchii* predominating, it being admittedly one of the most useful of plants for decoration at Christmastide. *C. vestita* in variety are also represented, also the distinct and much less common *C. masuca*, the flowers being first blue, changing with age to port-wine colour. *Oncidium Forbesii*, *cheiroporum* with twenty spikes, and varicosum; *Sophronites grandiflora* in rich masses; *Lælia autumnalis*, *Dendrobium bigibbum*, *D. formosum giganteum*, which continues so long in beauty, and *D. superbiens* which continues still longer—the plant for which Mr. Williams had a first-class certificate having remained in beauty (the same flowers) for thirteen weeks; *Odontoglossum nevadense*, very distinct; *Oncidium Weltoni*, fine variety; *Dendrobium Johannis*, various *Cypripediums*, and the curious *Masdevallia polysticta*—upwards of fifty flowers—are some of the Orchids now flowering at Holloway. Advancing for flower are the striking *Angræcum sesquipedale*, *Phalenopsis Schilleriana*, fine spikes, which probably produce fifty or sixty flowers, and *P. amabilis*. In the cool Orchid house *Odontoglossums* are showing freely, the plants being in admirable condition; and equally so are fine masses of *Cœlogyne cristata*. In fine contrast with the Orchids, and adjoining them, is the fine collection of Filmy Ferns, some of the more slender of the *Trichomanes* being grown on the old stems of Tree Ferns about a foot in length, each protected with a glass shade—chaste ornaments for rooms.

In other houses we noticed a wonderful plant of *Rondeletia speciosa* major, valuable for affording a supply of bright flowers for cutting; *Ipomæa Horsfallia*, flowering in 48-sized pots; new varieties of *Azalea* of the *amœna* type, which Mr. Williams is now sending out, and which will prove welcome acquisitions to those who obtain them, flowering as they do so early and so freely without much forcing, and giving colours bright and new. *Camellias*, of which there is a fine collection; a late white *Chrysanthemum*, flowers small and numerous, and just expanding, is proving useful for bouquets; *Ericas mutabilis* and *Bowieana*, and *Daphne indica rubra* are also attractive now. Brightness is provided by *Solanums*, the best of all of which is *Empress*, but this is not so plentiful as older varieties.

Amongst ornamental-foliaged plants many fine *Palms* arrest attention, from the massive *Verschaffeltia splendida* to the slender *Cocos Weddelliana*. *Kentias*, too, are both elegant and rich in colour, and rank amongst the most useful for decorative purposes. Amongst Ferns *Gleichenias* are noticeable, and the soft refreshing green of *Microlepia hirta cristata* improves in beauty as it increases in size. Plants with brighter foliage are provided in *Crotons* and *Dracenas*. Of the former Prince of Wales is quite one of the most beautiful, *Williamsii* is massive and rich, and *Burtoni* is striking by its deep orange-yellow markings and its rich contrasting green. *Dracenas* are equally fine—*Frederici* as an elegant table plant, also Mrs. Bause; while more massive and rich in colouring are *Bausei*, *Berkleyi*, and some others of the *Anerley* seedlings. The nursery throughout is in admirable condition, and a visit to it and its genial owner is always enjoyable.

MESSRS. CUTBUSH & SON, HIGHGATE.—When at Holloway it is natural to travel onwards and upwards for a little distance to see the prettily situated nursery of this old firm and its respected head. But to see flowers at Highgate the "bulb season" must be selected, when the conservatory is bright indeed. Only a few Hyacinths are now advancing, the prize bulbs being yet buried outdoors with cocoa-nut fibre. If gardeners and Hyacinth growers generally who desire to excel in the culture of these flowers could see how they are protected at Highgate and Coombe (Messrs. Veitch & Sons) they would cease starting their bulbs under greenhouse stages. "A hint is as good as a nod," &c.; and we pass on. The feature of Highgate at this season are the handsome shrubs, especially standards of Bays, Hollies, &c., imposing pyramids (grand lawn ornaments), of the Caucasian Laurel and the Magnolia-like *Laurus rotundifolia*. Weeping trees, too, are a specialty; Young's Weeping Birch, very elegant; Ashes, Limes, Elms, &c., which are prepared with great care. These trees when heavily draped, as we saw them, with frost crystals resembled fountains of silver, and the effect produced was singularly chaste. The houses were filled with plants, but chiefly Palms and other plants of that nature. The hardwooded plants, such as Camellias, Ericas, and Epacris, are grown in the purer air of Barnet, and are draughted to Highgate as required. Fourteen thousand Epacris are annually grown by the firm, and other plants in proportion. At present the flowering plants chiefly consist of Ericas hyemalis, very fine; caffra, gracilis, and colorans, all of which are extremely useful for decorative purposes at this season of the year.

MR. WILLS, FULHAM AND ANERLEY.—Since Mr. Wills purchased the Fulham Nursery a few months ago great alterations have been made, an open frontage having been formed next the Fulham Road, and new structures have been added to the extensive ranges of glass that previously existed. The large stock of flowering and ornamental-foliaged plants in Mr. Wills' nurseries afford evidence of the public taste in reference to plants and flowers for home adornment, nearly all the products of the two establishments being devoted to what may be termed domestic purposes, and in addition large quantities of flowers and numbers of plants are purchased to meet the daily demand for them. As a rule flowers and very large plants, such as Palms and Azaleas, are grown at Fulham, and Ferns and choice fine-foliaged plants, such as Crotons, Dracenas, Nepenthes, &c., are provided at Anerley. At Fulham a house has recently been erected solely for growing the white Lapageria, and another for Tea Roses. The Lapagerias are planted out, and the Tea Roses are in pots. When Mr. Wills finds out how admirably Tea Roses succeed when planted out in a stove temperature, as they are grown in the Pine stove at Lambton Castle, and in briskly heated pits as in Lord Londesborough's garden at Norbiton, he will probably adopt the same mode of culture for producing "buttoniers" of the first quality for Christmas.

The collection of cool Orchids is being greatly extended at Fulham, and well the plants look; but the spikes are cut as fast as they are produced. The same remarks apply to the beautiful *Lælia anceps*, which is grown by hundreds. A large house is entirely filled with Begonias of the Rex type, so great is the demand for these plants for various purposes of decoration. Another house is planted with Gardenias—a perfect thicket of them for affording cut blooms. Another house contains *Pancreatium speciosum* and fragrans, the flowers of which and Eucharises are always acceptable. In one of the houses we noticed several plants of a striking *Zamia*, the fronds of which were deep red in colour and highly effective. Bulbs are grown by thousands packed as closely as possible in shallow boxes, and rich soil and copious supplies of water do the rest. This is all that can be said about Fulham; and as to Anerley, if anyone desires to see a Fern, a Dracena and Nepenthes manufactory and other plants rare and popular increased and cultivated well, they will find such work well carried out there by Mr. Bause.

MESSRS. OSBORN & SONS, FULHAM.—It is very gratifying to all interested in the prosperity of this old establishment to learn that under the energetic management of the sole surviving male representative of the firm, Mr. R. Osborn, and able coadjutors the nursery is in a very improving state. Fruit trees and Vines in pots are a great specialty, and the stock of them is both extensive and excellent. In the houses there are plenty of foliage and flowering plants, including Ferns and climbers of the leading varieties suitable for decorative and other uses, usually to be met with in large nurseries. In the show house there is a great variety of Palms, *Araucaria excelsa*, *Aralia Sieboldii*, *Phormium tenax variegatum*, Camellias, Ferns, Aucubas

beautifully set with berries which are now changing colour. *Laurustinus*, *Primulas*, *Cyclamens*, &c., all alike healthy and useful. In the stoves the Dracenas, Crotons, Pandanus, Palms, Ferns (noticeably *Adiantum farleyense*), &c., in variety and of various sizes, are remarkably clean and healthy. Among the Palms we noticed attractive plants of *Areca crinita*, A. Herbstii, *Cocos Weddelliana* and *Kentia canterburyana*, as being particularly well adapted for table and house decoration.

In the hardwooded house the Ericas and Epacris look particularly well, and promise an abundance of bloom. *Acacia grandis* will shortly be covered with its miniature yellow balls, and dwarf plants of the useful pure white *Jasminum grandiflorum* are flowering freely. *Lomatia propinqua* is a very graceful green-foliaged plant, and does well in a cool house. In an intermediate house *Tropeolum Ball of Fire* trained along the roof is flowering freely. Libonias are also attractive. In this house is a good stock of the much-improved varieties of double *Primulas* raised by Mr. Gilbert of Burghley, and certificated by the Royal Horticultural Society, which this firm will shortly send out. The colour of Mrs. A. F. Barron is blush slightly striped with red; Princess, white slightly blotched with red; White Lady, a good white; and the Marchioness of Exeter, white slightly spotted with pink. The plants are more vigorous, flowering freely, the individual flowers much larger and more double than the old varieties.

Among the hardy shrubs *Euonymuses* in variety are very attractive, they are suitable for either pots, shrubberies, or beds.

MESSRS. C. LEE & SONS, HAMMERSMITH.—The Christmas display of this firm is now arranged in the Royal Horticultural Society's Gardens at South Kensington, and a splendid display it is of hardy ornamental shrubs, for which a gold medal was awarded at the last meeting of the Committees. This fine collection merits a fuller notice than has yet been accorded to it or than can be given now. Such notice must be deferred to a future issue of the Journal, for notes of plants of such perennial beauty are always seasonable.

CHRISTMAS ROSES.

ROBUST hardy perennials, comprising some of the gayest and earliest flowering of winter or spring plants. Hellebores produce their flowers at a season when few others can brave the inclemency of the weather, the genus belonging to the same natural order (*Ranunculaceæ*) as Winter Aconite, one of the first flowers of the year.

The whole of the species delight in moisture and some in shade, but shade is only essential when the soil is light and shallow, the plants thriving well in the full sun where the soil is deep and retentive. One of the greatest defects in their culture is disturbing them. All they require is planting in soil moderately enriched, deep, retentive or rather moist, and in slight shade in shallow soils, but the shade should be that of a deciduous kind so as to admit of the plant enjoying the full light in the early part of the year. Beyond keeping them clear of weeds, and giving a mulch about the plants in autumn they require no further attention, continuing to grow and increase in size and beauty annually, indeed when undisturbed they succeed to admiration.

Propagation is effected by dividing the plants when in a dormant state, or by seeds, which should be sown so soon as ripe in the open ground and covered lightly with fine soil.

Owing to the fickleness—uncertainty of our climate, Christmas Roses cannot always be depended upon at the festive season. I lift a few roots of the early-flowering varieties in early autumn, pot them in pots that will hold the roots nicely, using rich compost, and place them in any light airy house from which frost is excluded, draughting them into heat if necessary so as to have flowers at Christmas. I have now flowers of *Helleborus niger maximus* and *H. olympicus*, and have had for some time past. The individual flowers are fine for ladies' hair, and the buds on the point of opening are excellent for the "button hole."

In the open ground to have flowers with certainty the plants should have handglasses with moveable tops, or frames placed over them, admitting air freely in mild weather, but protecting from heavy rains and snow, further placing mats over the lights in severe weather. The blooms are much finer thus cared for than when they have not received any attention. The finest plants I have seen were grown upon a south border in front of a house—a stove. They were in a double row, the plants being about 2 feet apart, and the soil a retentive loam,

the surface being mulched with short decayed dung. In winter they are covered with spare lights, a lean-to being formed by placing the lights just beneath the spouting of the house. The supply of flowers afforded by these plants is wonderful—the gardener says they are far more useful to him than any plants he grows occupying similar space. The improvised frame has sufficient heat from the house against which it is placed to exclude frost, flowers being produced from early December onwards.

Helleborus niger.—The Christmas Rose is an appellation derived I think not so much from the flowers, which in mild seasons begin to expand towards the close of the year, as from the opening flower or buds resembling the bud of a Rose joined to the time of flowering. It is a native of the mountainous woods in many parts of Europe—Austria, Piedmont, Greece, the Pyrenees, and the Apennines, and is an old favourite, having been introduced in 1596. The plant grows from 9 to 12 inches high; leaves rather large, smooth, pedate, and pro-

Fig. 72.—HELLEBORUS NIGER.

duced after the flowers. Flowers large, cup-shaped, white or lightly rosy, borne in scapes from the end of December to March. The flowers are the purest in colour at first opening, afterwards changing to pink, and becoming green before fading. *Helleborus niger maximus* is the finest form of Christmas Rose, the flowers being large, nearly white when fully expanded, and very beautiful in bud. It is a magnified *H. niger*, flowering more freely, and nearly a month earlier. It should be in every garden.

H. orientalis is plentifully found in the east, on mountains in most parts of the Levant, on the Bythinian Olympus, and about Constantinople. It is synonymous with *H. officinalis* and

H. olympicus ruber, and is the Black Hellebore of the ancients. The flower stems grow about 18 inches high, more when the plants are vigorous, with forked peduncles bearing large solitary flowers, with the sepals more or less pointed and permanent, when young white, slightly stained with purple at the edge, changing to green when old. The radical leaves are on long stalks, pedate, regularly serrated on the margins; the floral are without footstalks, palmate, and finely toothed. It usually commences flowering with me in early December, but this year the plants have not yet flowered, attributable to division of the plants in spring, the wrong time for increase. The flowers are produced with the leaves, or rather fresh foliage

precedes the flowers. Altogether it is a very desirable species, and very hardy.

H. olympicus has many synonyms—viz., *colchicus*, *guttatus*, *abchasicus*, and *olympicus albus*. Radical leaves palmate,

Fig. 73.—HELLEBORUS ORIENTALIS.

segments oblong linear, and toothed on the margin except near the base, which is entire; floral leaves large, stalkless, sharply serrated on the upper half. Flowers cup-shaped, white, slightly tinged green; sepals bluntly egg-shaped, persistent, produced on forked flower stems 12 to 15 inches in height, they and the leafstalks mottled with reddish brown spots. It flowers with

me in December onwards, and is a fine species from the Bythian Olympus.

H. odoratus is, as its name implies, sweet-scented, the flower stems rising 12 to 15 inches high, forked near the top, having large solitary greenish white flowers. The sepals ovate, oblong, and permanent. It is a native of Hungary, and flowers about the same time as the preceding, being much finer assisted with protection.

There are many other species of Hellebores, but they do not flower until later in the winter, and do not come under the head of Christmas Roses, though they are fine for the herbaceous border, being alike interesting and beautiful.—G. ABBEY.

ORANGES.

ORANGES are pre-eminent amongst Christmas fruits, and the following notes abridged from the *Standard* will be read with interest at this season:—The importation of Oranges has recently commenced. Our supply comes chiefly from St. Michael's, one of the Azores Islands: from Terceira and Fayal, also belonging to that group; from Valencia, and several other Spanish ports; from Lisbon, Villa Real, Aviero, and Oporto, and from Palermo, Malta, and other ports in the Mediterranean. The earliest arrivals are from Spain, Portugal, and Sicily, the famous St. Michael's Oranges being a little later. The St. Michael importation does not last much beyond the end of May, and this class of Orange is at its perfection about Christmas, and then it is the best Orange that can be got, though complaints are now heard in the trade that the St. Michael growers have of late rather grown for quantity than quality.

The St. Michael's are now brought to this country exclusively in steamships, each carrying about 10,000 boxes; but a new vessel will be in the trade this season which will bring from 20,000 to 24,000. The boxes in this branch of the trade contain about 350 Oranges in each, though they are not counted, as are the numbers sent in the boxes from Palermo and Valencia, the latter containing 420 or 490, and the former 200 of large and 360 of small fruit. Probably there are more Oranges imported from Valencia than from all other ports together. The St. Michael's are packed in the dried leaves of Indian corn, but all other Oranges in paper.

The "Blood" Oranges, as they are called, come mostly from Valencia, but a few from Malta, from which latter place we also get the egg-shaped fruit. Both of these command much higher prices than ordinary consignments. The aromatic and delicious "Tangerines" hail from St. Michael's, and also from Lisbon, varying very considerably in price according to the supply. Seville Oranges come from the place of that name, and, as everyone knows, are used exclusively for making marmalade and orange wine. For both these purposes, however, the Palermo "bitters" are really better adapted; and it may not be generally known that the best marmalade of all is produced from the Shaddock—a sort of cross between an Orange and a Lemon, and named after a Captain Shaddock, who brought it from China, or as some say, from Guinea, and planted it in the West Indies, whence we now derive our limited supply. It is the bitter element in the Seville and Palermo Oranges which fit them for marmalade, as it preserves the skins while they dry.

The great bulk of St. Michael's and other Oranges are landed at Fresh Wharf, Thames Street, but those from Lisbon generally in the London Docks. The fruit is shipped to London merchants, who advance large sums of money to the foreign growers, and then it passes at once into the hands of the brokers, who sell it by auction, holding sales from three to five times a week, according to the season. Pudding Lane, Thames Street, is their head-quarters, and, if not quite an Orange grove, is busy enough with the Orange trade; long strings of white-stockinged "fellowship" porters carrying the boxes almost all day long without intermission during the busy season from the riverside to the warehouses. A large quantity of the fruit sold finds its way to Duke's Place, a quarter of the Hebrew region of Houndsditch, where it is resold to shopkeepers and costermongers. This locality is redolent of Oranges, and it is no exaggeration to say that you may often walk for yards there ankle-deep in decayed Orange pulp and peel. As it is a somewhat delicate subject to touch, it may be as well not to say anything about the price of Oranges as realised at the brokers' sales; but a few statistics of the quantity imported may be interesting. Twenty years ago it was thought rather a wonderful thing that the metropolis should be supplied with one hundred millions of Oranges yearly. There are now sold in Pudding

Lane and its vicinity something like three or four times that quantity, of which by far the greater portion is consumed in the metropolitan district.

The increase in the trade is due in a great measure to the abolition of the duty. Formerly 2s. 6d. per box was the impost; in 1853 it was reduced to 8d.; and altogether abolished in 1861. Last year 732,000 packages came to London. A steamer with 10,000 to 12,000 packages brings somewhat over one Orange each to the three and a half million inhabitants of the metropolis. Glancing at importations to other ports, we find that last year Liverpool received 715,000 packages (a large portion of which were transhipped to America); Hull received 227,000, and Bristol 110,000. If we add to these the packages received at minor ports, we shall have in round numbers nearly two million packages; and these again would represent something like a consumption in the United Kingdom of seven hundred million Oranges annually. Every year is more than likely to see a large increase on these figures. Last year, according to a calculation made by the Board of Trade, there were imported of Oranges and Lemons together 3,533,781 bushels, representing a money value of £1,549,765, first hand.

GARDEN FENCING.

I THANK all those contributors for their practical suggestions communicated to the Journal respecting fencing for the Experimental Garden. As the site of the garden is at Sandy in the centre of the Bedfordshire market-garden district there is little need for especial protection from cattle; but as experiments will be carried on it is necessary that a reasonable protection should at once be afforded against all intruders, and as yet I cannot discover anything so well adapted to meet all requirements as a wooden wall and a paled post and rail fence, and in the economical construction of which so much depends upon the local materials available. But here timber of all the usual kinds is reasonably cheap. Stretched wire netting can be quickly fixed at a moderate price, takes up but little space, and as a temporary fence is tolerably secure against two-legged marauders; for a south side where little shade is required I think it may be used advantageously, and seems preferable to flat bar fencing.

Quick Thorn, Holly, Privet, Spruce, or other green fence, except for the purpose of shelter or to act as a breakwind, is undesirable, as, in addition to the period which must elapse before a secure fence can be formed, the roots travel far in search of nourishment, and when the hedge becomes established it exhausts the ground for a distance of at least 6 feet on each side; and allowing 4 feet for the width of the fence, a space of upwards of 5 yards of valuable ground is almost monopolised, and this continued round a three-acre piece would amount to a serious diminution. The neighbouring market gardeners here are so fully alive to this that they shelter their Cucumbers and other tender crops with rows of Rye or staked Peas. Holly fences do remarkably well on the greensand in this locality, and in the favoured parish of Aspley Guise near Woburn, now much resorted to by patients suffering from pulmonary complaints, there is a hedge of Holly by the roadside from 20 to 25 feet high, nearly a mile in length, and almost without a break; and in the pretty village of Old Warden near here there are well-kept hedges of many kinds of variegated and other Hollies intermingled, which are charmingly luxuriant and healthy.

In the Bedford allotment gardens on a cold drift clay is a perfect hedge of Sweetbriar, 5 feet high and nearly 300 yards in length, extending round three sides of one of the allotments, and forming one of the most perfect and secure fences I have ever seen. And to show how much may be done by using the right materials for a live fence in a particular locality, I have seen in the Atlantic-washed coasts and saline atmosphere of the counties of Galway and Mayo good sound hedges formed of *Fuchsia Riccartoni* 12 feet high, and with others as thick as a man's arm, and where scarcely anything else but Elder will grow. The beautiful *Escallonia macrantha* in the more favoured spots in that locality is also used for dwarf garden fences.

Some years ago I tried in Lincolnshire various strong-growing Roses for divisional garden fences, and I found nothing equal to the hardy and vigorous H.B. Charles Lawson; it is a free and rapid grower, and when well cut-in at first makes a dense and secure hedge, and I intend again using it in the formation of the Rose garden in the Experimental. I have a suspicion that in most localities good old Gloire de

Dijon might be used for the same purpose; and doubtless some of your readers have hit upon other materials which may be of advantage for use on particular soils and in particular localities.—T. LAXTON, *Bedford*.

LIVERPOOL CHRYSANTHEMUM SHOW.

THE blooms exhibited at the above Show, according to Mr. Ollerhead's letter on page 448, were without quality, size only having been the aim of the growers. We know that some of them were overgrown, but we do not hesitate saying that the first-prize blooms (Mr. Tunnington's) were in form, colour, and general condition excellent. We ask Mr. Ollerhead to give his candid opinion respecting these blooms, and also of the first-prize six plants. Mr. Wallis of Keele Hall includes the first-prize twenty-four blooms with the others as being coarse, and describes Mr. Ollerhead's as "a nice even lot," and according to Mr. Wallis's remark it would appear that he thought the Wimbledon blooms entitled to a prize; yet if we remember rightly, when Mr. Ollerhead first saw Mr. Tunnington's blooms he admitted their superiority, and it is evident therefore that they must have possessed other good qualities besides mere "size."

We would now point to other matters of paramount importance. On what principles are Chrysanthemum growers to prepare their blooms for the future, and by what points ought judges to be guided to a right decision in making their awards? How can a judge decide on the quality and the age of the blooms if the lower petals are removed and only a compact small ball of the centre of the bloom is left to be shown? With such treatment a "nice even lot" could soon be made, but what is to guide the judge to the conditions of the bloom when the guard petals are gone, as we suppose they are shown in the south? There are blooms under cool treatment which require six weeks or more to open before the centre petals are properly developed; in this time the guard petals are fading, and such blooms are of no use for showing at Liverpool, while on the other hand they would be fine blooms with a portion of the petals removed as shown in the south. We are at a loss to know if a bloom with its lower petals removed is a Chrysanthemum proper or only half a flower: this is a point that should be made clear.

The bloom we consider suitable for exhibition should be perfect in form, containing all its lower petals, and being at the same time well filled in the centre and as large as it is possible to grow it without being loose, ragged, and coarse. The first-prize blooms, in our way of thinking, were exhibited as Chrysanthemums ought to be. If Mr. Ollerhead thinks differently we hope it will be good enough to point out their faults for the purpose of affording instruction. The growers in this neighbourhood are anxious to have some recognised rule to direct them in the future. Are the blooms to be perfect, containing their lower petals, or may they be removed and the centres shown? and what varieties are allowed to be shown as incurved flowers, and if the blooms are to be shown on paper collars or not? If some idea is given of the standard to be attained we shall know in what form to exhibit in case of a contest next year in London, Birmingham, or elsewhere. I send by this post four blooms as grown in this neighbourhood for ordinary decoration. They are as they are cut from the plants, and, as you will see, a little past their best.—WILLIAM BARDNEY, *Norris Green*.

[The blooms are good as grown for decorative purposes, but they do not possess the solidity requisite for exhibiting at the southern shows.—EDS.]

YOUR correspondents Mr. Bardney and "ALLERTON"—(the latter I observe does not give his proper name)—both complain of my having omitted to give praise to other exhibitors who took part in the various competitions. I simply felt it my duty to make the now historical exposure and I left the remainder to the discretion of your reporter. They both say I have given a correct account: this I always endeavour to do, and I feel they will pass the same verdict on my last letter, which I hope has met their views. Your correspondent errs when he says that a stand containing Fingal and Faust would be disqualified in the south of England. This would not be so, but an exhibitor would find that such coarse blooms would put him several points in the rear of his opponents with more compact blooms of the Rundle type. He is also, in my opinion, equally in error when he says they were two of the finest blooms in the Show; had he said two of the largest and

coarsest-petaled blooms, counting the fewest points of merit, he would have been right. As I before stated, it is like putting a coarse Drumhead Cabbage against well-finished blooms and deciding in favour of size.

As to the challenge of your correspondents to contest honestly and fairly with growers from any part either in or out of London if we only give them an invitation. I have to reply that I publicly gave them an invitation to Kingston, and told them what money and cups were in store for the successful competitors. The Liverpool growers must not forget that their representative at the Aquarium, Westminster, with his twenty-four blooms was nowhere against the southern growers. As regards the explicitness of our schedules, I enclose you a copy of the Kingston schedule, which is a fair sample of those issued about London, to compare with the Liverpool one. In the latter you will see prizes are offered for so many large-flowered and Pompon varieties. One would suppose the former meant large-flowered of any type, but on inquiry through the press I found it means incurved varieties only. I should like the Kingston schedule to be forwarded to "ALLERTON," and I ask him where we lack explicitness.

As to names of varieties, whoever heard of an exhibitor writing to his opponent to know what dishes of fruit, vegetables, or what varieties of plants or cut flowers he was going to stage against him? The Liverpool growers must use judgment in the matter if they are going to compete against the south.

As regards their challenge to meet us at any Chrysanthemum show out of London, or even in London, I think I may take the responsibility of saying that we accept the challenge under the following conditions—viz., that the growers of Liverpool and northwards subscribe £10, £20, or £25, as may be approved of, to pit against an equal sum contributed by the southern growers, for the purpose of purchasing a challenge cup or trophy to be contested for next year, as may be arranged for, by the north and south countrymen. We need not depend on two cultivators to make the awards. I think Kensington will be the most suitable place for the contest, and the Floral Committee the best judges to make the awards, and I have no doubt they would be very pleased to make arrangements to meet the views of the exhibitors as to date of show, &c. If £50 could be raised it would make a handsome prize and bring out our best talent in Chrysanthemum growing, and would also be of great benefit to the Royal Horticultural Society. If this scheme is approved, Dr. Hogg, as Secretary of the Society, will by my request act as treasurer to the fund. I shall be glad to see any practical suggestions in the Journal relative to carrying out in a proper and satisfactory manner the proposed Chrysanthemum tournament.—J. OLLERHEAD, *The Gardens, Wimbledon House, S.W.*

HEATING BY PARAFFIN STOVES.

PARAFFIN stoves may be used in greenhouses without injuring the leaves of Geraniums or any other plants in the house, by placing a large basin of hot water on the stove. If the water is warm when placed in the house it will keep hot all night, a guinea stove keeping a small greenhouse at the present time at a temperature of 45° during the night without other heating. The stove used is Ripplingill's patent. My son has used the stove mentioned most successfully in warming his greenhouse this winter, which was full of Zonal Geraniums.—E. G. H.

THE EARLY HISTORY OF THE APPLE.

THERE can be little doubt that the Romans on their arrival in Britain found Apples growing there; for the Crab is indigenous to the soil, and the Apple is but a cultivated Crab. Cæsar makes no allusion to fruit. He describes the Britons as more a pastoral than an agricultural people. But some parts of the island, he says, were already fruitful in corn, especially, as it appears, in the districts inhabited by the Belge, who had recently crossed over from the Continent. ("De Bello Gallico," v. 14.) Tacitus, who in his "Life of Agricola" gives the most interesting and trustworthy account of ancient Britain which has come down to us, does not mention either Apples or Pears, but expressly says, "The soil is adapted for produce of all kinds except the Olive and the Vine, and other things (fruit trees) accustomed to grow in warmer countries, (and is) fruitful: they are quick in coming, slow in ripening, both effects arising from the same cause—the excessive dampness of

soil and climate."—"Vita Agric." 12.) There can be still less doubt that the Romans as they settled down in Britain brought with them the varieties of fruit they had been accustomed to use in Italy, though there is no distinct record of their having done so. They ever loved to surround themselves with the plants of their own country, and it is to them we owe the introduction of the Elm, the Box, the Walnut, the Cherry, and the Pear. The coarse pot herb *Alexanders* (*Smyrnum olusatrum*) is generally found in the neighbourhood of Roman earthworks, and unwittingly they brought the Roman Nettle (*Urtica pilulifera*), which still haunts some of the ruined Roman stations in England. From the country in which the Romans settled the fruit there would gradually spread through the country. In the third century the Romans obtained permission, it is said, of the Emperor Probus to introduce the Vine into Britain, and soon made wine from the fruit.

It is natural to suppose also that as the native inhabitants receded before the invaders, they too would carry with them their own varieties of Apples into the most remote districts of the country. The Druidical legends—for such evidence as they may afford, support this idea. At a later period, during the fifth and sixth centuries, there is some indirect evidence to show that this was the case. The native Britons sought refuge from the Saxons amongst the mountains of Wales, and many of them fled from thence to the north-western coast of France, called Armorica, which in consequence of this emigration received the name of Brittany, which it has since retained. From Wales they carried with them their Apple trees, and one remarkable instance of their having done so is recorded in the "*Liber Landavensis*." It is thus mentioned by Montalembert in his "*Les Moines d'Occident*," which, translated, says: "When St. Eriue and his eighty monks from Great Britain landed in Armorica (Brittany), and marked the site on which the town which bears his name was afterwards built: they acted just as the soldiers of Cæsar did in the forests sacred to the Druids. They first surveyed the ancient woods with curiosity," says the chronicle: "they hunted everywhere through them, and finding a branching valley with pleasant shade and a stream of clear water running through it, they all set to work . . . frequently replacing the trees of the forest by fruit trees, like the British monk Teilo, who planted with his own hands, aided by St. Samson, an immense orchard—a true forest of fruit trees—three miles in extent in the neighbourhood of Dôl."—(Book vi. p. 394.) Teilo was the son of Tegwedd, who was also the mother of Bishop Afan of Buallic (Builth). She is said to have suffered martyrdom at Llandegveth, near Caerleon. Teilo received his religious education at this college of Iltutus, or Iltyd, situated at the village now known as Llantwit Major in Glamorganshire. Teilo succeeded Dubricius in the see of Llandaff; and on the death of St. David he was appointed to the see of Menevia (St. David's). He placed his nephew Ishmael there as suffragan, and continued himself at Llandaff, with the title of Archbishop. "He is known as one of the three blessed visitors of the Isle of Britain, Dewi (St. David's) and Padarn being the other two. They were so called from the zeal with which they preached the faith in Christ, to rich and poor alike, without fee or reward, and from their deeds of charity."—"Williams' Cymry," p. 133.)

Samson was bishop of Dôl, but it seems there were two bishops of Dôl of the same name, and both were educated at the college at Iltutus. In early life Teilo passed over to Armorica and spent some years with his old fellow student, Bishop Samson of Dôl. The "*Liber Landavensis*" says, "St. Teilo also left there another testimony of his patronage, for he and the aforesaid Samson planted a great grove of fruit-bearing trees to the extent of three miles, that is from Dôl as far as Cai, and these woods are honoured with their names until the present day, for they are called the 'Groves of Teilo and Samson.'"—"Liber Landavensis. Lfr. Teilo. Welsh M.S. Soc." chap. iii. p. 346.) This orchard still existed in the twelfth century under the name of "*Arboretum Teliavi et Samsonis*." ("*Vie St. Brieuc*," by the Canon of La Devision, 1627, cited by La Bordérie). Tradition states that the planting of this orchard first led to the manufacture of cider in Normandy, and certainly no notice of it is to be found until some centuries afterwards, when the cider of Normandy began to attain the celebrity it afterwards gained. Teilo died A.D. 540, and was succeeded at Llandaff by his nephew Oudoceus, also a person of eminent sanctity. Samson died A.D. 599. There are twelve churches in the diocese of St. David's founded by St. Teilo, or dedicated to him, of which Llandeilo Fdwr in Car-

marthenshire is the principal. In the diocese of Llandaff the cathedral is dedicated to St. Teilo and St. Peter, and there are five other churches, including Llanarth, Llandeilo Cresseney, and Llandeilo Pertholly in Monmouthshire.

In the Sarum Missal there is a special blessing for Apples, which is appointed to be used on St. James' day, July 25th, but this form does not appear either in the Missal or Breviaries of the Hereford use.

It must also be mentioned that it is a common belief in the midland counties that Apples are not fit to be cooked until they have been christened by the showers of St. Swithun on July 15th.

From the time of the conversion of the Anglo-Saxons to Christianity, and for many succeeding centuries, even as late as the fourteenth century, the cultivation of fruit was chiefly carried on by the ecclesiastics. The monks were men of peace and study, and living in retired spots depended upon their gardens for much of their food. Through ages of war and bloodshed they pursued their peaceful avocations and cultivated the soil with sedulous industry. Many a monk like Scott's Abbot Boniface of Kennequhair has found great pleasure in the Pears and Apples he had grafted with his own hands. The abbey garden is always observed to occupy the best and most sheltered situation that could be found; and by their foreign connections the monks were enabled to obtain from more favourable climates, not only better kinds of vegetables and more choice fruits for their own delectation, but also valuable medicinal herbs for the treatment of the sick poor in their neighbourhood. The ruins of most of the old abbeys afford to this day proofs of the care bestowed by their former inhabitants in introducing foreign plants. From the gardens attached to these institutions they have often been found by botanists to wander into the neighbouring fields and woods. Asarabacca (*Asarum europæum*) recently found by the Woolhope Club in the Forest of Deerfold is one of these medicinal plants. Thorn Apple (*Datura Stramonium*), Belladonna (*Atropa Belladonna*), Stinking Groundsel (*Senecio squalidus*), the plant always grown in nunnery gardens (*Aristolochia clematitis*), are other examples; and more might be mentioned. As early as 674 there is a record that Brithnot, the first abbot of Ely, laid out extensive gardens and orchards which "he planted with a great variety of herbs, shrubs, and fruit trees. In a few years the trees which he planted and engrafted appeared at a distance like a wood, loaded with the most excellent fruits in great abundance, and added much to the commodiousness and beauty of the place."—"Hist. Eliens. apud Gale," lib. ii. c. 2.)

"The Ancient Laws and Institutes of Wales," published by the Commissioners of Public Records in 1841, which comprise the laws supposed to have been enacted by Howel Dda about the early part of the tenth century, modified by subsequent regulations under the Princes of Wales previously to the subjugation of Wales by Edward I. (1283), give several references to the great value of Apple trees.

In the Dull Gwynedd, the "*Venedotian*," or "*North Wales Code*," book iii. chapter 20, is entitled, as rendered in the English translation, "On the worth of Trees this treats:—"

"Section 8.—Every tree that shall bear fruit is of the same worth as the entire Hazel grove, excepting the Oak and the Apple tree." (*Mem.* A Hazel grove was valued at twenty-four pence.)

"Section 9.—A graft four pence without augmentation until the calends of winter after it is grafted."

"Section 10.—And thenceforward an increase of two pence is added every season until it shall bear fruit, and then it is three score pence in value, and so it graduates in value as a cow's calf."

"Section 11.—A sour Crab tree is four pence in value until it bear fruit."

"Section 12.—And after it bears fruit it is thirty pence in value."

There is no reference to the Apple tree in "*The Ancient Institutes of England*."

In an alleged account of the "*Antient Saxon rite of coronation*" as recorded in the time of Edgar? (959-975), the following passage is given as forming part of the blessing pronounced by the archbishop or bishop at a Saxon coronation:—

"May the Almighty Lord give thee, O King, from the dew of heaven and the fatness of the earth, abundance of corn and wine and oil. Be thou the Lord of thy brothers, and let the sons of thy Mother bow down before thee; let the people serve thee, and the tribes adore thee. May the Almighty bless thee with the blessings of heaven above, and the mountains and the valleys; with the blessings of the deep below; with the blessings of *Grapes and Apples*."

Wild Apple trees were not uncommon in this reign. William of Malmesbury says (lib. ii. cap. 8) that King Edgar in 973, while hunting in a wood and separated from his followers, was overcome by an irresistible desire to sleep, and alighting from his horse he lay down under the shade of a wild Apple tree.

Henry of Huntingdon, in describing a quarrel that arose at the court of Edward the Confessor between two of the sons of Earl Godwin, represents one of them as departing in a rage to Hereford, where his brother had ordered a royal banquet to be prepared. "There he seized his brother's attendants; and cutting off their heads and limbs he placed them in the vessels of wine, mead, ale, pigment, morat, and cyder."—"Henry of Hunt." vol. vi. p. 367.) It must, however, be admitted that although this history was written in 1154 it was not published until 1576 by Saville, when it is possible that the last word "cyder," by that time the common drink of Herefordshire, may have been added.—(*Herefordshire Pomona*.)

HOW AN INVALID GREW SOME ROSES.

OUR garden is small; situation sunny, but much exposed; soil light and sandy. I longed for Roses, but was told I need not attempt to plant any. "They won't grow," said wise friends and experienced gardeners whom I consulted, so for years I had to content myself with bedding plants. I was not content. I loved such plants only with the love any flower can command. You cannot care deeply for things that the first frost destroys, and that must be taken away to be seen no more.

Meantime some little shelter had sprung up round our little flower garden—a Yew hedge on the north side, and a Privet hedge on the south-west. We cannot wholly shut out the east, though the house is to some extent a protection from that quarter. I ventured on buying nine or ten Rose trees from a gardener near who had a small but good collection. They were planted in three of the flower beds, but not all the ground was allowed. "Bedding plants would look well, and would do the Roses no harm." However, in spite of the surrounding parasites the standards did fairly. I had made a beginning. I had gathered Roses.

Waiting another year and still studying my manual, besides corresponding with a practical Rose-grower who recommended the Manetti stock as likely to do better than the Briar on sandy soil, I ordered some standards and some dwarfs. The order included Gloire de Dijon for the east aspect of house, Maréchal Niel and Climbing Devoniensis for the south-west, a dozen or two Hybrid Perpetuals, and two or three of the hardier Teas. The soil was enriched with loam and dressed with good stable manure.

Even here discouragement was at hand with the remark—"You are making the soil too rich: the Roses won't flower." But the Roses did flower. They bloomed better and better every year as I learned to understand them and to treat them carefully; and even with all the drawbacks of soil and situation the blooms were generally fairly good and often positively fine. Now and then I lost a weakly standard, once a dwarf, and never a Tea Rose.

I have now about a hundred varieties. All the bedding plants are routed. The Roses have it all to themselves, save a little space near the windows for Primroses, garden Daisies, and spring Forget-me-nots, and the Geraniums, &c., in autumn.

Being an invalid I am shut up generally at pruning time, but a friendly gardener looks after my trees twice a year, and does what is needful for the Roses.

My first trees were planted in 1873. If anyone should desire to know what Roses do best in such soil as I have described, and what varieties have given me the earliest, the latest, and the sweetest blooms, I shall be glad to communicate my experience to the Journal.—A. M. B.

PETROLEUM OR PARAFFIN AS AN INSECT KILLER—A CAUTION.

I AGREE with Mr. W. Taylor as regards the utility of paraffin oil for the destruction of insects on plants, but I would caution those who use it not to try his recommendation of "one wineglass to a gallon of water." Two years ago I was recommended to try this strength; the result was that it not only killed the vermin but also the plants. It, perhaps, might not be too strong for matured hard wood, but on soft-wooded and tender plants it was destructive. I therefore reduced the strength to a wineglass mixed with two gallons of

water, but found this still too strong, for in watering or rather syringing a row of French Beans wherever the dose had been twice applied they died; but on reducing the strength to a wineglass in a bucket of water I found it most beneficial to all descriptions of plants, and look upon it as one of those things a gardener can use against all kinds of plant vermin—taking care to amalgamate the paraffin and the water with the syringe before each ejection.—G. O. S.

[A wineglassful of anything is an indefinite quantity, there being large and small wine glasses. What is reckoned as a wineglassful among apothecaries is $1\frac{1}{2}$ fluid ounces. All receipts ought to be stated in fixed quantities.—EDS. J. OF H.]

NOTES AND GLEANINGS.

AT the INTERNATIONAL POTATO EXHIBITION held at the Crystal Palace in September last, about thirty new varieties of Potatoes were brought forward by exhibitors who were anxious to obtain for them critical consideration. It was found to be impossible to deal fairly with so many in the brief space of time then at command, and hence there were no certificates awarded. The Committee charged with the task of inquiring into the merits of new varieties have now made their final selection, and have awarded first-class certificates to the two varieties which Mr. Shirley Hibberd has described as follows:—*Radstock Beauty*.—A coloured round, inclining to pebble shape, even and somewhat angular, rarely attaining to large size, the skin tawny white, smooth, and silky. The eyes are few but conspicuous, the side eyes being of a rosy purple colour, with arched brows of the same tint distinctly defined; the eyes of the brown or nose end clustered in a patch of a somewhat darker shade, giving to a good sample an extremely pleasing appearance. The growth is moderate, the produce mostly of smallish ware size, plentiful, and clean; the flesh fine in texture, mealy, dry, and delicately flavoured:—*Woodstock Kidney*.—A white kidney, of oblong shape, extremely even and smooth. The skin is tawny white, silky; the eyes few and inconspicuous, set level with the general surface in a small cluster of dots at the crown or nose end. So regular in form is this variety that a fair sample may be likened to a model turned in a lathe. The growth is moderate and compact, the tubers are plentifully produced and mostly of middling ware size, and are in the very least degree affected by disease. The flesh is yellowish, fine in texture, and of the most delicate flavour. This is, all points considered, one of the finest varieties hitherto submitted to the International Committee.

It will be remembered that the SCOTTISH HORTICULTURAL ASSOCIATION some time ago offered prizes of £3, £2, £1, and 10s., for competition by under gardeners, members of the Association, for the best four plans of kitchen gardens, with fruit, plant, and forcing houses, gardener's house, and offices, complete. We are requested to call the attention of our readers to the fact that the time for forwarding the plans is now at hand—namely, January 1st, 1879. The plans must be sent to the Secretary, Mr. John Methven, 15, Princes Street, Edinburgh.

THE FERN WORLD.—Messrs. Sampson Low, Marston and Co. are about to commence the publication, in a series of shilling monthly parts, of Mr. Francis George Heath's "Fern World." Part I will be ready with the January magazines.

"N. C." COMMUNICATES the following in reference to the FROST AT NENAGH:—"A self-registering thermometer, placed on a stand raised one foot above the snow, fell during the week ending December 14th, four nights to 15° Fahr.; on 14th to 10°; and this morning (17th) it had fallen to zero." The soil is dry. Our correspondent "W. J. M." writing from Clonmel states that the weather has been so severe there as to have killed several shrubs in his garden.

THE dates of the Floral Meetings in connection with the MANCHESTER ROYAL BOTANICAL GARDENS, to be held in the Town Hall next year, are March 18th and April 29th. On the last-named date the Exhibition of the National Auricula Society (northern section) will be held in the Town Hall. The usual Great Show will be held in the gardens at Whitsuntide, and the National Rose Society's Northern Show on July 12th. The Cottagers' show will be held August 4th.

WE have been astonished to see exposed for sale in Covent Garden Market splendid specimens of GOLDEN QUEEN HOLLIES from 6 to 10 feet high, and which have evidently been trained with great care. Such specimens as

these are so valuable that we cannot imagine that nurserymen would thus offer them for sale; and private owners usually cherish such handsome shrubs so highly as to refuse to part with them. From whence are such beautiful and valuable specimens obtained?

— MR. ELLIS writes to us as follows on the SEVERITY OF THE FROST IN THE NORTH:—"At Bothalhaugh, two miles and a half east of Morpeth in Northumberland and four miles west of the sea, the thermometer fell to 10 degrees below zero (42 degrees of frost), on Friday, December 13th. Bothalhaugh is in a very sheltered valley 35 feet above the sea level. There are several places in the neighbourhood where the mercury fell below zero, but none where so many as 10 degrees were marked to my knowledge. This corroborates the experience of the Rev. F. W. Stow, who, in the *Times*, gives the great difference between the temperature on the high ground at his house and that in the valley below."

— THE balance sheet of the NEWCASTLE BOTANICAL AND HORTICULTURAL SOCIETY shows that the total receipts for the year amounted to £2116 15s., and the expenditure, including £238 17s. 6d. due to the Treasurer from last year, was £2238 0s. 7½d., leaving a balance of £121 4s. 9½d. due to the Treasurer. The receipts include the following items:—Subscriptions, £1214 18s. 7d.; admissions—spring show, £184 13s. 6d.; summer show, £469 16s. 7d.; autumn show, £212 0s. 9d. The payments included £649 1s. 6d. for prizes and £373 12s. for music. Messrs. Taylor and French, who have done so much for the Society, have, solely owing to the pressure of their private business, resigned their position as Honorary Secretaries—a decision that was received with unanimous expressions of regret at the recent meeting of the Society.

WORK FOR THE WEEK.

FLOWER GARDEN.

MEN during the present "slack time"—we envy those having one—may be usefully employed in preparing the necessary soil for spring potting, and turning compost for the enriching of flower beds, pushing forward every description of work that will ease that at the busy season. Look frequently over the stock of bedding-out plants. Frost and snow are not favourable to them; the plants can have but little air, and if kept warm they make only enfeebled growth. Avoid that as much as possible by keeping the plants cool, and give no more water than to prevent the foliage flagging. Keep succulents as dry as possible and free from frost. *Verbenas*, *Petunias*, &c., require a rather dry atmosphere, aiming at 45° as a minimum, and excluding frost. *Pelargoniums* should be kept gently moving, nothing is gained by starving them in winter. 45° to 50° is a suitable temperature for the variegated kinds, and 5° less for the green-leaved varieties. *Coleuses*, *Alternantheras*, and *Iresines* require plenty of light and heat, 50° being a minimum, and require to be kept moist and moving during the winter.

FRUIT GARDEN.

Proceed with the pruning and dressing of espalier and wall trees—Apple, Cherry, Pear, and Plum. Pear trees infested with scale may be freed by dressing them with petroleum, applying it with a brush, and American blight upon Apple trees may be similarly destroyed. Tared string is suitable for securing the branches of espaliers, and medicated shreds answer perfectly for securing the branches of wall trees. When the condition of wall fruit trees is unsatisfactory an examination of the roots should be made, especially in the case of unfruitfulness resulting of over-luxuriance, which may generally be remedied by judicious root-pruning, using a sharp knife for the purpose, extracting from the soil the portions cut off, as if left they would probably foster fungoid growth to the injury of the live roots. In the case of exhaustion resulting from overbearing or poverty of soil, the soil should be removed down to the roots, exposing a considerable portion of them, avoiding injuring them in the least degree; and if there be any dead or decayed roots remove them, then cover the roots with turfy loam with a third of thoroughly decayed manure. Tread the soil firm and mulch at once with littery manure. Trees are frequently rendered unfruitful by having the surface roots mutilated with the spade.

FRUIT HOUSES.

Pines.—Preparations must be made for producing ripe fruit during the months of May and June. Smooth-leaved *Cayenne*, Black *Jamaica*, and *Charlotte Rothschild*, which failed showing fruit during October and November, will not now throw up in time to ripen at the period in question, and attention must be directed to such as attain perfection in less time—such as the different kinds of the *Queen*, *Enville*, *Providence*, &c. Choose forthwith those plants which have an enlarged base with a tendency to open at the centre, signs of the fruit being shortly visible, placing them in a light house or pit, affording brisk

bottom heat of 85° to 90°, and a top heat of 60° to 70° at night, and 70° to 75° by day, and 10° more when the external conditions are favourable. A genial atmosphere should be maintained, but do not produce it by steam from the hot-water pipes, as syringing the plants overhead once or twice a week is ample and then very lightly, on fine afternoons damping the house. See that the soil is in a proper condition as to moisture, using tepid water with a dash of guano in it, applying it copiously when required, which will be about every ten days. Former instructions as to plants in other stages will need to be continued as before advised.

PLANT HOUSES.

Conservatory.—This structure will now be gay with Christmas Roses in pots, *Laurustinuses*, *Andromeda floribunda*, early-flowering *Rhododendrons*, sweet-scented flowers such as *Lilacs*, *Violets*, *Roman* and *Paper White Narcissuses*, *Roman Hyacinths*, *Cytisuses*, *Cyclamens*, *Primulas*, *Heliotropes*, *Richardias* brought into flower in heat, the stately distinct flowers of which are very effective; *Epacris*, wintering-flowering *Heaths*, some of the early-flowering *Acacias*, *Azalea indica* vars. flowered in heat; *Camellias*, late-flowering *Chrysanthemums*, *Epiphyllums*, *Lily of the Valley*, *Amazon Lily* (*Eucharis amazonica*), *Hippeastrum pardinum*, *Plumbago rosea*, *P. coccinea* *superba*, *Poinsettia pulcherrima*, *Euphorbia jacquiniiflora*, *Thysacanthus rutilans*, *Centropogon Lucyanus*, *Apelandra cristata*, *A. Roelziana*, *Dalechampia Roelziana* *rosea*, and many other plants which make a very effective display. As some of those are from structures somewhat warmer than conservatories generally a little extra heat should be given, not, however, exceeding 50° by artificial means, affording at the same time increased humidity, the atmosphere of conservatories often being kept too dry for a majority of forced plants, hence their short continuance in good condition in such structures; therefore supply the plants well with water at the roots to compensate to some extent for the loss of moisture by the foliage, and if there be evaporation troughs fill as many as will afford the requisite humidity, which will prevent damping the paths, which should be kept dry and comfortable for the visitors to this structure.

TRADE CATALOGUE RECEIVED.

Shinn & Co., Niles, Alameda County, California.—*Descriptive Catalogue of Fruit Trees.*

TO CORRESPONDENTS.

* * All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

BRIARS (*W. Tipton and E. Thody*).—Write to Mr. Ware, Hale Farm Nurseries, Tottenham, London.

GREEN ROSE (*R. K. and S.*).—It is *Rosa viridiflora*, a well known but not a common plant. It was figured in vol. xxiii., page 132, of this Journal.

LIST OF FRUITS (*J. W.*).—*Pears*: Peach, Fondante d'Automne, Doyenné du Comice, Marie Louise, and Winter Niles. *Plums*: July Green Gage, Purple Gage, and Coe's Golden Drop.

BLACK CURRANTS UNFRUITFUL (*J. W., King's Lynn*).—We think the evil of which you complain is chiefly attributable to imperfectly ripened wood. The shoot you have sent is very immature. If several of the branches are removed from the bushes so as to admit sun and air to the foliage, we think fruit buds would form freely. Perhaps, also, the soil requires draining. The *Primulas* are good, but none of them so dark as the variety you mention. We have no authority to give the address you require, but we know the fruits referred to are produced as stated in the article to which you refer.

AZALEA AMEXA (*Spade*).—Large worms in the pot would so injure the roots and also check the drainage as to cause the leaves to fall from the plant. Dissolve a lump of lime weighing a pound or more in a gallon of water, and when clear water the plant with the lime water. The worms will then come to the surface and may be destroyed. Do not disturb the roots until the plant has flowered, when it may be repotted if necessary. The temperature is right.

CO-OPERATIVE GARDEN STORES (*A. F.*).—We do not know of any stores of the nature indicated. If there are such, a letter addressed to the Manager will be delivered by the postal authorities or will be returned to you.

PETROLEUM AS AN INSECTICIDE (*R. C.*).—I have seen no ill effects resulting from the petroleum reaching the roots of plants, and I do not think there is any danger that the small portion I recommend will harm them, but I generally turn the pot plants on their sides when syringing them. Permanent plants, such as *Stephanotis*, however, have been operated on in an upright position. Besides, we know that some able correspondents have recommended petroleum in a dilute form to be sprinkled freely over *Carrot* beds to check the *Carrot grub*, and, again, it is now a common practice to dress *Peas* and other large seeds with undiluted petroleum. The soil, therefore, in which they are sown must be highly impregnated with it, and nothing but good comes of it as I can testify. Some of my friends have tried petroleum as a fertiliser for *Caulidowers* and other gross-feeding plants, and have thought well of it, but I cannot speak of this from my own knowledge.—WILLIAM TAYLOR.

SLOW-COMBUSTION BOILERS (*R. A. P.*).—Upon due consideration we think our reply will be most useful to you if we avoid direct answers to the questions raised in your letter, and offer a few facts relative to the matter for your guidance. The combustion of fuel in all boilers is slow or fast, very much in proportion to the setting of the boiler and the care shown in

the manipulation of the soot door and damper, both of which are intended to check draught, and the damper is also meant to retain heat about the boiler and to prevent its escape up the chimney. In a saddle-back boiler heating a range of vineries some 80 feet in length, the fire is often left untouched for eight hours, and a given temperature steadily maintained in cold weather by simply leaving only a very slight opening in both soot door and damper, the fire being of course thoroughly established, and the furnace full of fuel and banked with fine well-damped ashes at the time of leaving it. We therefore counsel you to retain your saddle-backs and to apply this hint. Also see if your boilers are well set. The fire should pass under the boiler, back along one side, over the top near the door, and along the other side to the shaft, so as to subject its entire surface to the action of the fire. To ascertain the number of feet of 4-inch pipe required for lean-to houses divide the cubic feet of air contained in the house by 30 for a temperature of 60°, and by 20 for a temperature of 70°. This will afford you sufficient data in calculations for houses of any size or form.

MACHINE FOR WASHING FLOWER POTS (T. W.).—A really efficient pot-washing machine would be a boon to gardeners, and if reasonable in price it would probably command a sale when fairly before the public.

CUCUMBERS BITTER (R. H.).—Bitterness of the fruit often arises from slow growth. If more active root-action can be induced, and the temperature of the house can be raised a few degrees, improvement will probably follow, and in spring the bitterness will probably disappear. The quality of the fruit hitherto having been good affords evidence that the fault is not attributable to the variety.

HEATING BY PARAFFIN STOVE (J. S.).—For preserving such plants as you name—Fuchsias and Geraniums—a temperature of 52° is unnecessarily high. With a good and well-managed lamp and good paraffin there should be little smell from the stove. If you have to make the stove very hot a shallow vessel of water should be placed on it to prevent the atmosphere of the house becoming too dry.

HARDY PERENNIALS FOR FLOWERING THE FIRST SEASON (Somerset).—*Antirrhinum*, *Delphinium* in variety, *Dianthus chinensis* vars., *Pansy* vars., *Verbena venosa*, *Pentstemon*, *Polythronum*, and *Viola*, they being forwarded in gentle heat. All hardy perennials are best raised from seed sown in May or June in the open ground, and they will flower with certainty the year following, *Phlox decussata* and *Adonis vernalis* not excepted. You may readily find the names of hardy perennials by referring to any descriptive seed catalogue.

ANNUALS FOR GREENHOUSE DECORATION (J. X. X. and W. W.).—We presume you mean hardy annuals, which, by sowing in gentle heat so as to forward them, can be had in flower early in the season, growing them in cold frames or with a little heat, it being essential that they have only sufficient heat to keep them gently moving. They must also be kept near the glass to prevent drawing, and have free ventilation to keep the plants sturdy. All the dwarf-growing kinds are suitable, a few of which are—*Asperula azurea setosa*, *Calandrinia grandiflora*, *Alyssum maritimum*, *Collinsia bicolor*, *C. candidissima*, *Clarkia integrifolia limbat*, *C. pulchella marginata flore-pleno*, *Kaulfussia amelloides*, *Nemophila*, *Nolana atriplicifolia*, *Eriogonum bistoria Veitchii*, *Schizanthus pinnatus*, *Silene pendula* and vars., *Whitlavia grandiflora*, and many others. Many of the half-hardy annuals are very effective when grown in pots. The names of hardy and tender annuals may be found in any catalogue.

SEEDS FROM SOUTH AMERICA (E. M. F.).—Your deciphering of the names appears correct, but 3 is probably *Asplenium gelatum*; 4, *Pteris scaberula*; 9, *Coprosma lucida*, greenhouse evergreen, loam; 10, *Pittosporum tenuifolium*, New Holland, loam with a little peat, greenhouse evergreen; 2 is no doubt *Todea*; it and 3 and 5 succeed in a greenhouse temperature, but should be raised in heat, the Ferns requiring to be moist and shaded, and Filmy Ferns, *Hymenophyllum* and *Todea*, constantly wet. The others should be sown in strong bottom heat early in March.

REMOVING BARK FROM VINES (Young Gardener).—We advise the loose bark to be removed; but scraping or peeling, so as to injure the live bark, cannot be too severely condemned. Aerial roots on the stems of Vines are often caused by defective root-action, but are more frequently resultant of a close and moist atmosphere, with frequent damping of the rods.

LAPAGERIA ROSEA (J. P. C.).—We should defer transferring the *Lapageria* to the orchard house until February or March, as the plant from being grown in a greenhouse will be likely to feel the change and suffer from frost if removed now, whereas by another winter it would be more hardy, and would better endure the cold; the roots being well protected it is nearly hardy.

STRAWBERRIES FROM SEED (J. E.).—Strawberries will fruit the following year if raised from seed sown in heat in February, some probably in the autumn of the first year. Slates or tiles should be about 15 inches long by 9 inches wide, placing them on both sides of the plants. Leaves are a poor manure for Strawberries, and no efficient substitute for stable manure, though in a decomposed state are useful. In the fresh state they are worthless, and should be at least half decayed before being employed. We should apply the guano in liquid form, pouring it between the rows after the plants come into flower, one ounce of guano to a gallon of water. You will gain little by raising plants from seed, very likely be much disappointed. Well-rooted runners taken from fertile plants afford the most satisfactory results.

ERRATUM.—The new Pear exhibited by Messrs. Wm. Paul & Son at the last meeting of the Royal Horticultural Society was incorrectly printed in our report *Theresa Nevill*. The correct name of the Pear is *Meresia Nevill*, as in the "Fruit Manual."

NAMES OF PLANTS (Somerset).—*Pinus Pinaster*.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

THE MANAGEMENT OF SWINE.

(Continued from page 477.)

WE will refer now to the pens recommended for store stock and fattening pigs. Having previously stated that the meal house, &c., should be in the centre of two ranges of buildings, the range

may be continuous and facing the south, unless from circumstances it may be necessary to take another line, when the building may face the west. We recommend that the building should be 20 feet space and be covered with a pantile roof, and be of the same height as previously stated—that is, the eaves to be 7½ feet from the ground level. A pitched path should be formed in front, raised 12 inches from the ground, in this case for defensive purposes only. In these sties we recommend a feeding path at the back of the shed, 3 feet wide with fixed iron troughs and flap shutters attached for feeding purposes, and communicating with the meal house, boiling house, &c. The divisions of the sties should be of iron, either flat bars fixed at about 6 inches apart and ½ feet in height, or sheet iron galvanised of the same height, the divisions to be 10 feet apart; this will leave after taking off the feeding path, &c., pens of 16 feet by 10 feet. The frontage may be of wood or sheet iron, and having a 2½-foot wicket to each sty, so that from the front earth, litter, and dung may be added or removed as the case may be. These sties will be excavated 2 feet deep below the ground level and feeding path, but the troughs being fixed instead of rising with the manure as it accumulates, a space next the trough 3 feet wide should be left on the ground level to give the pigs a footing level with the feeding trough. The portion of the sties to be excavated will therefore be 13 feet by 10 feet. It is, however, sometimes excavated the whole distance of 16 feet, and then instead of only filling-in about 8 or 10 inches in depth of earth over the whole of the pen, the earth is filled-in 1½ foot in depth in front of the troughs, giving a footing for the animals at feeding time, and an absorbent floor throughout. This in daily use will be littered with straw or other materials as cleanliness dictates, and be allowed to accumulate as long as convenient, but the dung should not be allowed to remain in one spot, but be spread over the pen each time that fresh litter is applied. A boar's pen may be placed at the far end of the building entirely separate from the other pens, the feeding trough being in the same range. An off pen adjoining, however, should be made for use (when a sow pays the boar a visit), with a wicket 2½ feet wide leading out of the boar's pen. The division between the boar's pen and the adjoining pen should be carried up to the cross beam—that is, 7½ feet from the ground level. The animal may then lead a quiet life without being disturbed by the other stock, and be fed with a moderate diet of vegetable food and cracked beans, or peas, or beanmeal.

We will now refer to the young pigs after being weaned. The sows having been removed from them and placed in a yard where dung is stored, the young pigs may be fed in the same pen, and there remain until they are old enough to be fed for fattening and be placed in the fattening sties before named. The food should now be in accordance with the time they will be required for killing. If for quarter pork of light weights, say from 60 lbs. to 80 lbs. each, they cannot be kept too high immediately they are weaned, and upon farms where butter or cheese-making is carried out there will always be a portion of whey or buttermilk available. This with barleymeal and a slight addition of bean or pea meal will make them fat in a short time, and afford meat of the best quality with a fair proportion of lean and fat combined. In the winter months the food should be given warm. When the pigs are required to be kept for a time as store animals, we object to their being allowed to run at liberty about a farmyard as they often are; first, because we know nothing of a farmyard except as a temporary manure store, and this under our advice should be occupied by the breeding sows as before stated; secondly, these animals we look upon as manure-making machines as well as profitable stock on the home farm; therefore, when they are kept in pens as before stated they will not only have left their manure in the most available state, but their health will be insured as far as management can contribute to it; at the same time their well-doing will be assured by the warmth and comfort of the pens, because warmth and regularity of temperature must always be considered an equivalent to a certain amount of food. When the pigs are required to be kept on for bacon at weights about 200 lbs. each, they should be removed to the larger pens, where plenty of room will be found for feeding, placing about six animals in each pen. Up to the time they reach seven months old they may be fed with cracked beans, peas, or maize about twice a day, and in addition during the summer months they may have a liberal allowance strewed over their pens of green fodder, such as trifolium, vetches, clover, and the cutting of borders containing hog weed, cow parsley, and coarse grasses, followed in the autumn by the earliest roots, such as carrots, turnips, and Swedes, also cabbages—in fact, anything except mangolds, which we reject altogether, as we have often seen young pigs killed by their use, and after death the lungs have been found decayed and often turned a black colour. This mode of feeding will keep the stock in a growing state, the beans and other broken grain contributing a good foundation for future fattening by making a good proportion of lean flesh, and the manure made will be good, because any portion of the green fodder not consumed will be trodden down and improve the accumulating manure.

When the store pigs are about six or seven months old they

may then be put to good food for fattening, and instead of green fodder eaten with beans, &c., they should have all trough food. In winter time it should be warm or cooked food, such as boiled potatoes, carrots, cabbage, &c., as much as they can eat without waste. These mixed with barley meal and bean or peameal will make meat fast enough and of good quality after about eight weeks' feeding. For the last fortnight of the period they should have meal only, this will make the meat firm and improve the value for consumption. We cannot however, leave the subject without referring to a method of feeding whereby a farmer of our acquaintance fed annually over one hundred hogs up to 200 lbs. each for a bacon factory, and they gave good satisfaction, being fed with mangolds cut and placed in troughs with meal alternately, and he assured us that it paid him better than any other mode of feeding he had ever adopted during the summer months. The mangolds were the produce of the previous year. We cannot contradict such evidence, but we may improve upon the mode of feeding by pulping the mangolds, adding the meal to make a pudding instead of giving the mangold and meal separately. In this way mangolds may, we consider, be used with safety and profit by pigs of full age, but not for animals under four months old. In the instance we have given the pigs made excellent bacon when finished-off by a fortnight's feeding with meal only.

When young sow pigs are reared for breeding purposes those should be chosen which have not less than twelve teats. The selected animals may when weaned be kept upon the same food as the pigs held on as stores for bacon, but they may have more liberty and be kept in a yard and store for manure as recommended for the aged sows. Sows will usually continue to breed until they are four or five years old with advantage, but care should be taken that they may be expected to farrow in the months of March and September.

The sort of pigs to be kept should be in accordance with the district and the climate, for nearly every county in the United Kingdom has a breed which is preferred by the farmers of the district. The most prominent stock, especially for exhibition purposes, are the large Berkshire, the smaller Sussex, and Improved Dorset as black pigs; but the white breeds are the large Yorkshire, the smaller being chiefly of the Middlesex and some other sorts; but for general purposes, instead of confining ourselves to distinct breeds we prefer judicious crossing both the larger and smaller breeds of the same colour. We cannot enter into the merits of different breeds on the present occasion.

WORK ON THE HOME FARM.

Horse Labour.—This is the dulllest time of the year for horse labour. Although tillage operations have been at a standstill during the late frosty and changeable weather, yet there is always work of some kind which may be found for the horses, such as carting gravel for the repairs of the roadways on the home farm. These repairs are too often done in a negligent manner. Whenever gravel is applied, and especially when the road is only wide enough for one vehicle to pass, it should be laid only in the middle of the road, extending to the wheel track on either side. The road will then be kept in shape, particularly when so made that the water can pass away freely. When the land is firm enough to bear the carts without cutting the surface long fresh dung may be laid out on the clovers and pasture land, and if the frost is hard manure may be drawn on to the land which has been stetched or banked up in readiness for the mangold or potato crop. The land will afterwards only require to have the stetches reversed and be ready for seeding and planting at the earliest season in the spring. When the horses cannot work on the land by dung-carting, &c., they may be employed in making heaps of earth in a convenient place in readiness for carting to farm buildings whenever earth floors for cattle pens, &c., are in use. All corn in the barns should now be threshed to prevent damage by rats and mice, for they are sure to increase rapidly from this time forward if the corn is allowed to remain. A large number of the rats may be killed by ferreting, but the mice are more difficult to deal with. The odd horse or horses will also be employed in carting roots from fields or pits for horse and cattle feeding, &c.; also carting hurdles for the shepherd, as the sheep will now be feeding off roots upon the land. When the sheep tread the land too much—as they often do when the weather is very wet, and especially upon the breaking-up of frost—the stock cannot feed roots on the fields without injury to the land for the next crop. In such cases the roots may be carted to a dry pasture for a few days' feeding. The carting of straw and hay for stock will also be going on; at the same time the straw and hurdles necessary for making a lambing fold for the ewes must employ the odd horse for portions of the day. The shepherd will know how to place the fold, as it should be near to some shelter by hedges or woods with a convenient drift way, &c., unless it is made on some part of the farm premises which will secure shelter and convenience also.

Hand Labour will now consist of cutting and plashing hedges, making banks and ditches, and attending to the outfalls of drains. The work of draining in the fields may now be done, as it is

easier to command a sufficient number of men for the work with out displacing valuable labour in the spring. The present season is more favourable than it usually is in the winter months for draining. We notice the subsoil is drier than the surface, thus facilitating the labour of underground draining. We shall not enlarge upon the subject at present, as we intend to treat of the drainage of different soils as a leading subject on a future occasion; we will, however, remark in passing that draining, although it may be done piecemeal, yet there ought always to be a plan showing the depth and distance apart of the drains. This calls to our mind that having some years ago set out and completed the draining upon a home farm, and having also furnished a plan of the drains in each field, the property was afterwards sold. The new proprietor, without reference to the plans of draining and the outlets, grubbed the hedges and filled in the ditches, which blocked the drains. Since then we have always been particularly cautious by calling attention to the fact that no underground draining ever ought to be done without being shown on a map or plan. It is now that the labour of women and lads is valuable in preparing roots for the cutter for feeding cattle and sheep, but we do not find that the women and boys are to be had as they used to be. We once never thought of employing men for such easy work where agility is so important, the men not being able to do more work than the women and boys, although receiving double the wages. The young store cattle, particularly heifers of one and two years old, where fed in yards and sheds, will require not only regular feeding with roots and straw or rough hay, but constantly fresh litter of dry straw; even this will not make a comfortable bed for them without the sheds and yards have been bottomed with earth for absorbing the liquid manure. This matter, therefore, should have attention, as it tells favourably both for manure and the comfort of the stock. On some home farms wood-cutting will now be going on, and it is advantageous to have this work completed by the middle of February, because the sap begins to rise in the underwood stools about that time, and the carting of the underwood can be done whilst the horse and manual labour is least valuable. The cutting of timber for repairs also should now be done, it being desirable that when the timber is required for repairs upon the home farm it should be cut in the winter time before the sap rises; even oak timber will be more enduring if cut now than when cut for the purpose of taking off the bark in the spring. It is now also that the carting away both of timber and the made-up underwood can be done without delaying more valuable labour, except in the case of very wet woodland or gullies, when the carting may be deferred with advantage until drier weather in the spring.

SHOW OF THE SURREY COLUMBARIAN SOCIETY.

THE newly-formed Surrey Columbarian Society held their first Show on the 10th and 11th at Guildford. The entries numbered 180, and the Show was a singular success for a first attempt. It was held in a well-lighted hall in the Commercial Road, which, being over the Turkish Baths, was of a most pleasant temperature—no small advantage in the present weather alike to exhibitors and Pigeons. Mr. Esquilant was the Judge, and we believe pronounced some of the classes excellent, specially those for Carriers. There were two special prizes: the one for the best bird in the classes for Carriers, Pouters, Barbs, and Fantails; the other for the best bird in the rest of the Show. The former went to Messrs. Cucksey & Flicker's Black Carrier hen; the latter to the first-prize little Red Turbit, the cup bird in the young Turbit classes at the last Crystal Palace Show.

Carriers had four classes. Cocks were very good. First a Black, second a Dun, with the finest wattle in the class, but a little short in body. The first hen was a very good Black. There were two well-filled classes of young birds. Pouters were few, but the first-prize bird good. Barbs were a good class. We thought the second-prize bird a very promising young one. Fantails were decidedly good. First went to the little White hen with beautiful carriage that took the cup last year at the Crystal Palace. Second to the flat-tailed cock which took the cup there this year. Tumblers were chiefly Kites, and not remarkable. Dragons.—The first-prize bird—a Blue—was well ahead of the rest. Turbits were interesting from the three prize birds being all celebrated winners shown against each other. First the little Red before mentioned as winner of the special prize. Second a Yellow hen celebrated for her frill and winner of many cups. Third a Black, and first at the Crystal Palace one year. Owls.—First and second were beautiful little White Africans. Second was the Palace and Birmingham winner, while the first hen was second at the Palace. Third an English Powder Blue, lovely in colour but deficient in head properties. Jacobins were not good. Short-faced Antwerps a well-filled class, and the winners very fair. Homers number about fifty. In the Any variety class rich-coloured Archangels were first and second, and a large Silver Runt third.

We must congratulate the promoters of this Show on the excellent management of their first attempt, and hope to see many more such on a still larger scale. We subjoin the prize list:—

PIGEONS.—CARRIERS.—Cocks.—1, 2, and 3, Cucksey & Flicker. *Hens*.—1

3. and Special, Cucksey & Flicker. *Young Cocks*.—1, 2, and 3, Cucksey and Flicker. *Young Hens*.—1, 2, and 3, Cucksey & Flicker. *POTTERS*.—1, A. Allen. 2 and 3, C. H. Kendrick. *ANY OTHER VARIETY*.—1 and 2, O. E. Cresswell. 3, W. Kent. *SELLING CLASS*.—1 and 3, Cucksey & Flicker. 2, W. E. Hutt.

THE KERRY BREED OF CATTLE.

FROM time immemorial Ireland has possessed a hardy, handsome, and valuable breed of cattle, although small in point of size. This is known as the Kerry breed, and it has retained its best characteristics notwithstanding that it has been treated with comparative neglect. Its value is now, however, better appreciated, and more attention has been paid to the development of its special characteristics. These are the production of a large yield of rich milk, taking the size of the cows into consideration, and when fattened of beef of rare quality. The Kerry cow is particularly well adapted for villa farming, as she is extremely docile, is easily kept, and produces milk rich in quality and in considerable abundance. We have known many instances in which Kerry cows have given sixteen quarts of milk daily for a considerable time after calving, and twelve quarts of milk per day may be reckoned a fair average when the cow is fairly fed. The milk is rich in quality and produces a good proportion of butter, say 7 lbs. per week as a rule; and when it becomes necessary to fatten her for the butcher the process is an easy one, whilst the quality of the beef is such that a Dublin butcher, whose customers are amongst the better classes, will always give 1d. a lb. more for it than for a fattened cow or heifer of any other breed. When fat the Kerry usually weighs about 4 cwt.

The fashionable colour of the Kerry cow is pure black, but some are red, especially in the case of the Dexter variety. The true Kerry is described in Pringle's "Review of Irish Agriculture," published in the Journal of the Royal Agricultural Society of England, as "a light, neat, active animal, with fine and rather long limbs, narrow rump, fine small breast, lively projecting eye full of fire and animation; with a fine white cocked horn tipped with black." The Dexter variety "has a round, plump body, square behind; legs short and thick, with the hoofs inclined to turn in; the head is heavy and wanting in that fineness and life which the head of the true Kerry possesses, and horns of the Dexter are inclined to be long and straight." The Dexter appears to be a

BUSACO, the property of Mr. James Robertson, La Mancha, Malahide, Co. Dublin. The first-prize Kerry bull at the Royal Dublin Society's Shows in 1875, 1876, 1877, and 1878; also first at the Royal Irish Shows at London—Kerry in 1875, Cork in 1876, Galway in 1877, and Dublin in 1878.

variety originally produced by selection, but whilst possessing its peculiar points it retains the milk and meat-producing properties

of the breed from which it sprung and to which it is justly regarded as belonging.

Mr. James Robertson, La Mancha, Malahide, Co. Dublin, has for some years devoted much attention to this very nice breed of cattle, and many persons in England have now become familiar

Fig. 75.

MISTLETOE, the property of Mr. James Robertson, La Mancha, Malahide, Co. Dublin. The first-prize Kerry Cow at the Royal Irish Show held at Cork in 1876.

with it through the excellent specimens which Mr. Robertson has occasionally exhibited or sold in England, and especially through the many handsome Keries which he exhibited last June at the International Show at Paris, where he was awarded a number of prizes. Mr. Robertson's bull Busaco has won seven or eight first royal prizes in Ireland, in fact he has never been beaten, although he had at different times to contend against superior animals of their kind. When Busaco was two years old he stood 34 inches in height at the shoulder, girthed 50 inches; while the length from the top of the shoulder to the tail was 38 inches.

VARIETIES.

WE have before us several fresh schedules of forthcoming Shows. The Stockport Show is fixed for January 10th and 11th. There are twenty-three open classes for poultry, with three prizes in each of £2, 15s., and 5s. In these classes the birds are shown in pairs. There are also forty-six local classes, in which the birds are shown singly. Pigeons have nineteen classes, all open, and are shown singly. There is a Dog Show in connection with the Poultry Show.

THE Reading Pigeon and Cage Bird Show is fixed for January 22nd and 23rd. There are no less than forty-six classes for Pigeons. Carriers have five classes, Pouters six, Dragons five, Antwerps seven, Tumblers three, Owls four, Turbitts three, &c. Canaries have twenty classes, Mules four, British birds six, Foreign birds four. We know by experience that the Reading Show hall is always well heated, and that delicate birds can be entered there with confidence.

WE quoted last week from the *Daily News* about the migration of British birds. Mr. O. E. Cresswell writes to us that he has lately seen in his garden, on the borders of Berkshire and Surrey, a rare British bird—the small spotted woodpecker. He has watched it day after day in apple trees, and on a green bank; apparently it is a bird of this year, not yet having its scarlet crest.

STRAW HIVES AT CRYSTAL PALACE SHOWS.

ON page 440 of the present volume of your Journal I find Mr. Pettigrew has endeavoured to support his statement in regard to the above subject by dragging my name forward to support his recollection of a conversation which he says he had with Mr. Bagshaw four years ago. His statement that straw skeps

were refused admission to the Crystal Palace Shows is a perversion of facts which Mr. Bagshaw, who is "a gentleman of unimpeachable veracity," very properly declines to support, either by his own word or by the production of documentary evidence.

That Mr. Bagshaw wrote to me several times I admit; but that in reply I ever wrote a single word which would admit of the construction Mr. Pettigrew puts upon one or the other, I utterly deny. Indeed from the first I had no such one-sided idea. The proposal to hold a Crystal Palace Show originated at my own fire-side. The first idea was simply to hold a meeting of bee-keepers, and after dining to discuss bee matters and make friendships. A proposition was made to that effect in the "British Bee Journal" of October 1, 1873. On January 1st, 1874, a first list of subscribers was published in that Journal, followed on the 1st of February by a proposed schedule of prizes subject to alteration. In the second class in its list, marked *b*, a prize was awarded of £2 and certificate "for the best skep or box hive for depriving purposes," and there were four other classes, *c*, *d*, *e*, *f*, and in which the straw hivist could have competed if he had chosen to do so, the prizes being of the same value.

Mr. Pettigrew at that time made no objection to them, though during the spring months his friends did what they could in the *Journal of Horticulture* to bring the movement into discredit. Mr. Symington replied in the "British Bee Journal" to a letter of Mr. Bagshaw's which appeared in the *Journal of Horticulture* on March 19th, 1874, explaining the nature of the proposed Crystal Palace schedule, and plainly showing that skeps could compete in four classes for hives and sixteen for honey. A copy containing Mr. Symington's communication having been sent to Mr. Pettigrew, how can he ignore it and charge the promoters of the shows with having excluded straw skeps therefrom?

Now up to this time the British Bee-keepers' Association had no existence, but I had received upwards of £70 towards the prize fund of the proposed show, and I then invited all those who had subscribed to a meeting at Camden Town, where I hoped "not only to revise the schedule of prizes to be offered, but to lay the foundation of a national society for the promotion of bee culture." The meeting took place accordingly on May 16th, 1874, and the British Bee-keepers' Association started into existence. But there was no alteration of the schedule that would exclude the skep or its produce from competition, though Mr. Hunter, in his eagerness to provide or cause to be provided a hive that should be within the reach of all cottagers, carried a motion which added to the wording of class 2, and made it read—"For the best skep or box hive for depriving purposes that can be supplied for 3s., exclusive of floor board, prize £2 2s. and certificate."

The Show was held, and it was a great success. Amongst other reports of it which appeared in the *Journal of Horticulture*, alluding to class 2 as above described, the writer says, "Some very good straw skeps were shown. One (No. 9) exhibited by W. Martin even was fitted with bars, but the prize in the class was we think justly awarded to Mr. C. N. Abbott for a veritable Woodbury, price 3s., with many improvements," &c. Thus we have Mr. Pettigrew denying documentary evidence which must have come under his notice. In the schedule of the Association for the second great exhibition at the Crystal Palace in 1875, prizes of 20s. and certificate were offered "for the best and cheapest skep for depriving purposes." The first prize was carried off by Messrs. Neighbour with a Pettigrew hive at 4s. 6d., Mrs. Pagden coming in second with her neat little skep at 1s. 9d. These are facts, and "facts are stubborn things."

I am sorry for Mr. Pettigrew's sake that he has rendered it necessary for me to ask you to publish these facts; but for the implication of my name I should have taken no notice of this subject. Those who desire a more minute understanding of my meaning should refer to Mr. Bagshaw's letter on page 91 of the *Journal of Horticulture*, 1874, and to the scorching denunciation with which his defence of the Manchester swindle was met in the succeeding week, page 113, by the straightforward steady and true aparian, "B. & W.," who does his best to keep the common weal of bee culture up to the times.

I remember that before the first Crystal Palace Show, 1874, took place Mr. Bagshaw asked me in a letter if in class 8, "For the largest and best harvest (of honey) from one stock of bees under any system or combination of systems," he could bring to the show the produce of a stock, and of all the swarms that had issued from it; and, it being our first show, I preferred to let the matter be decided by the Committee, which must have been appointed or I could not have been the "treasurer," and in my reply I probably said his query was a "poser" which the Committee must decide upon, and doubtless from Mr. Hunter's hands he received the desired information.

That Mr. Pettigrew perfectly understood the position of affairs, and took in the whole situation, may be best gathered from his "proposed schedule of prizes for the Manchester Show" wherein the first set of prizes in class A were offered "For the largest and best results obtained from one stock of bees managed on any system, either swarming or non-swarming," the prizes being respectively 80s., 40s., and 20s. Unfortunately the season 1875 was a very bad one, and as a consequence the thing collapsed. In the

schedule first referred to, written by Mr. Pettigrew, prizes were offered in class 9 "for the best and neatest observatory or unicombed hives" to the amount of "60s., 40s., and 20s.;" and in class 10, "for the most ornamental hive of glass, or glass and wood," prizes were offered, in Mr. Pettigrew's own hand, to the value of 40s. and 20s., with the stipulation that in both instances the hives were "to be exhibited with bees in them." Further on, in class 13, he proposed a prize of 20s. "for the best bar-frame hive," and an equal amount for "the best straw hive." Later, in the same schedule, he offered prizes of the value of £5, £2, and £1 respectively "for the best and largest collection of hives, bee furniture, and other necessities for an apiary;" and in the last class No. 10 offered 20s. "for a collection of the best and cheapest supers (empty) for general use in an apiary." This occurred in May, 1875, yet now in 1878 Mr. Pettigrew alludes to the outcome of the great show by the British Bee-keepers' Association at South Kensington in August last as "puffed-up novelties," though the text in their schedule was almost identical with his own in respect of the foregoing, and the meaning undoubtedly the same. I have no desire to comment on Mr. Pettigrew's method of teaching; and as it will be evident to the meanest capacity that he and I are not in the same boat, I need say no more than that I have felt it necessary, by a plain statement of facts, to clear the air during this dull season, that he may not in darkness or ignorance run the stem of his craft into the stern of mine.—C. N. ABBOTT.

[We have been obliged to omit much of Mr. Abbott's communication, which was discursive, both from want of space and from its irrelevancy; confining it entirely to the subject in dispute.—Eds. J. or H.]

OUR LETTER BOX.

BRITISH BIRDS (*Col. Bulger*).—We regret that we cannot remember the dates of the papers you require. They would, we think, be a portion of the week's issue previously to that in which the articles appeared in this Journal.

CANARY MOULTING (*Stamford*).—Your bird certainly should not be losing his plumage just at the season when it is most required. If your pet is kept in a room where fire or gas is used this, in a great measure, will account for the continual casting of feathers. In its semi-weekly condition it would be hazardous to life to remove the bird into a colder temperature just now. If the cage is suspended high up in the room, lower it some couple of feet, and at night time cover it over. Spurt on the bird with your mouth a little sherry wine, and place in the bird's drinking vessel some scraped liquorice. The "great variety of extras" may have tended to upset the bird's system; in other words, you are killing your pet with kindness. Excepting occasionally treating your bird with a little biscuit and lettuce seed, let its food consist of the seeds you have named, but scald the rapeseed before supplying it; also a piece of salt to peck at, and plenty of grit sand and fresh water. The best way to keep birds in good health is to give them good sound seed and pure water, and keep them in an even temperature free from draught.

SUDDEN DEATH OF CANARY (*A Merry Christmas*).—We cannot fully account for the sudden termination of your Canary's life. Such mishaps are of everyday occurrence through fits and other causes. Like other animals birds are subject to diseases of various kinds, and from your description of the attack which brought about its death it is just possible your bird might have died through heart disease. You did wrong by keeping the two birds "in one cage all the year round," more especially as you state "the birds have been fighting a good deal of late." Instead of promoting harmony you have allowed them to encourage their pugnacious propensity until the weaker of the two has gone to the wall. Such excitement would naturally bring about prostration, and the holding of the bird before the fire would hasten death through suffocation. We cannot attribute the cause of death to the small quantity of hempseed you gave, especially as the hen bird, which is strong, partook of the same food. We advise the keeping of the sexes separate until the proper time for pairing them to breed; then it is more likely the birds will pay due respect to each other.

REMARKS.

18th.—Bright clear day with sunshine, snow all disappearing.
19th.—Very clear fine day, bright sunshine; cold starlight night.
20th.—Thick and very dark all day.
21st.—Clear and cold dry day, intervals of sunshine; rather thick in afternoon; starlight evening. Snow in night but not deep.
22nd.—Fair but dull morning, snow till 11 A.M., and heavy from noon till 4 P.M., total depth 1½ inch. Fine and clear at night.
The frost continues, and though not severe is becoming noticeable for its duration.—G. J. SYMONS.
